Each hypothesis is load-bearing. Drop the wire tie (`polyTie`) and a certificate could prove its region fact about one wire while running the coefficient check on a polynomial over a different one — concluding a bound about a value the premise never constrained. Drop the predicate-shape clause and a convex-but-not-conic predicate falsely transfers along an extension ray (the proof section computes a two-line counterexample: certified coefficients  $\{0, -1\}$  both satisfy  $\square \geq -1$ , yet the polynomial dips to  $-2$  on the ray). Drop the coefficient recomputation and the conclusion is unrelated to the polynomial. Drop the simplex tie or full-dimensionality and the barycentric reading of the premise breaks. The checker's own scope guard (constant canonical forms at any dimension; coordinate polynomials only over 1-dimensional regions when the extension set is nonempty) is part of the soundness story: everything beyond the proven fragment is refused, never accepted on faith.

**notes** Predicates enter through a deliberately closed-world grammar: finite conjunctions of scalar hole-atoms  $s \cdot \square \bowtie c$  with  $s > 0$  and  $\bowtie \in \{\leq, \geq, =\}$ , classified for convexity (always) and conicity ( $c = 0$  throughout). Comparators outside the grammar are refused — conservatism that can lose completeness, never soundness. The elementwise atom semantics batch the conclusion: a tensor-shaped polynomial term gives per-entry predicate application for free.

**What the coefficient side-condition means — and what it does not.** The rule's main premise appears in the payload as the single name `allForwardDiffBernCoeffsSatisfyP`, so this book binds its meaning by displaying the definition chain in full, from the checker sources. Reading the chain: `satisfiesPredQ` substitutes a candidate rational for the designated predicate-hole wire and runs the *closed* formula evaluator — the predicate is judged at a concrete value, by exact  $\mathbb{Q}$  arithmetic, never at a wire. `Term.asCoordPoly?` translates the polynomial term into the region's ambient coordinates, by one of two routes: an `idx`-free term goes through its wire-keyed canonical polynomial (at most one wire, remapped to coordinate 0), and a projection-indexed term maps each projection  $w[j]$  to coordinate variable  $j$ . `bernConeCoeffCheck` then gates (simplex tie, full-dimensionality, and the scope guard: non-constant `idx`-free polynomials only over 1-dimensional regions; multivariate coordinate forms only at  $S = \emptyset$  with all projection indices in range), computes the full forward-difference Bernstein coefficient table of the translated polynomial over the masked vertex list, and sweeps every grid entry through the predicate.

What a skeptical reader should confirm by eye in the definitions below: the conclusion formula never enters the check — only the polynomial, the region data, and the predicate do (the conclusion is pinned separately, as the syntactic substitution of the polynomial into the predicate's hole); nothing in the chain reads a valuation, so the check cannot covertly assume anything about wire values; and every false branch of the guards is a refusal — the fragment boundary (dimension, extension set, index range) fails closed. Semantic truth is established only in `sound_bernCone`, from the region premise's validity.

## Correspondence (Steele display $\leftrightarrow$ Lean)

**a bound Lean statement CHANGED since certification — re-review and re-certify** The dictionary below is a reviewer-certified statement of how the mechanized statements above interpret the displayed rule: display metavariable  $\mapsto$  Lean binder, each display hypothesis  $\mapsto$  the premise or side condition carrying it, the display conclusion  $\mapsto$  the goal — with any deliberate difference in width between display and mechanization named outright. Certification is recorded as a hash triple over (the displayed cell, the extracted statement texts, this dictionary's own text); if any of the three changes, this block turns amber until a reviewer re-certifies. The correspondence claim itself remains editorial — reviewer-grade, not machine-checked; its machine-checked successor types each soundness statement against the rule as a structured object, and supersedes this block per rule as it lands.

Judgment frame as in Ax; sub-derivation premise as at WEAKEN. The general statement is `sound_bernCone`; `sound_bernCone_empty` (certified alongside) is its  $S = \emptyset$  specialization, through which the general proof routes that case.

- $x \mapsto \text{termX} : \text{Term}; \Delta \mapsto \text{simplex}; S \mapsto S : \text{ExtensionSet}; d \mapsto \text{degree} : \text{Nat}; p \mapsto \text{polynomial} : \text{Term}; P \mapsto \text{predicate} : \text{Formula}$  (the hole-atom grammar of the note, its hole a designated wire).
- the region premise  $\Phi \vdash x \in \mathcal{R}(\Delta, S) \mapsto \text{ih}$  with `hregionPost : regionPremise.post = .inRegion termX simplex S;  $\Phi$`  shared via `hpre`.
- the wire-tie premise  $\text{wires}(p) = \emptyset \vee (x = w \wedge \text{wires}(p) \subseteq \{w\}) \mapsto \text{hpolyTie}$ , the same disjunction verbatim — note `termX = Term.var w`: the display's “ $x = w$ ” means the region term literally *is* that wire.
- the two-clause predicate premise  $\mapsto \text{hpredShape}$ : the conjunction of ( $S$  nonempty  $\rightarrow$  conic) and ( $S$  empty  $\rightarrow$  convex), by the decidable predicate classifiers.
- the displayed coefficient sweep  $\mapsto \text{hcoeff} : \text{allForwardDiffBernCoeffsSatisfyP simplex S degree polynomial predicate}$  — one name whose meaning this book binds by displaying its definition chain in full (the intro above); the display's first premise line (simplex tie, full-dimensionality) and its scope-guard premise have no Lean binder of their own because the checker's gates certify them: *absorbed*, as `PCONSTEXACT`'s closedness is.
- conclusion  $\Phi \vdash P(p(x)) \mapsto$  the goal under `hpostApply : applyPredicateToTerm predicate polynomial seq.post` — the conclusion is the syntactic substitution of the polynomial term into the predicate's hole; the “at  $x$ ” lives in the wire tie, not in a separate application node.

Width note, two-sided and honest: the statement is *proven* at every hypernet, sequent, and payload — and `hcoeff` is satisfiable only inside the displayed scope-guard premise (constant canonical forms at any dimension; non-constant `idx`-free forms over 1-dimensional regions; multivariate coordinate forms at  $S = \emptyset$  only), so the certified reach of the displayed rule is exactly its guard-passing fragment, by refusal outside it — never by unverified acceptance. Conversely nothing in either statement is wider than the display: every hypothesis is consumed, and the display's own two-clause predicate license is carried exactly.

## Lean verifier receipts

module BernsteinLogic.Soundness; bound build a20d90e66c13... (bound from receipt a9c0e34d3e3c9c8c, 2026-08-03T21:30:36Z). A receipt records that named checking layers accepted a build: (module, compiled-artifact SHA-256, environment SHA-256, checker layers), minted when the checking gate ran; the store receipts attesting the bound build are listed with the layers each run credited. Nothing here asks the reader to trust the store: every layer is an independently runnable program over the quoted sources — rebuild the module and re-run the checkers to reproduce the verdict. Receipts attesting superseded builds credit no layer and are omitted from this rendering (the count of omissions, if any, is noted below).

#### gate-layer coverage of the bound build:

build (lake build (elaboration)) current

replay (leanchecker (official kernel replay)) stale only

hardened (safe\_verify (hardened screen)) stale only

decorrelated (lean4export + nanoda (decorrelated kernel)) current

**comparator: fixture DemoBernCone** the three-implementation comparator harness (compiled machine code, kernel-reduction probes, and the compiler-IR interpreter, all executing the same elaborated checker functions) carries the worked example's certificate — an  $Ax \rightarrow \wedge E \rightarrow \text{BERNCONE}$  chain at  $S = \emptyset$  — as its fixture DemoBernCone. The suite passes only when all three paths return identical verdicts on it, and the kernel path probes two-sided (reporting its own verdict rather than confirming the compiled one), so a false green would require the same wrong answer from execution stacks that share nothing below the elaborated definitions.

## HOL verifier receipts

[documentary](#) hol-strict CLEAN over the ported checker chain: theory bern\_catalogue, 472 theorems, 0 cheat-tagged, 0 nonstandard axioms (whitelist: DISK\_THM; the four bool axioms) — verification run of 2026-07-22 on an isolated build host, scripts sha-matched verbatim to the sources cited here (git blob e41b9ed0...). The ported receipt table replays the BERNcone rows of the Lean development's own receipt battery: the worked-example accept (bernConeCoeffCheck at  $S = \emptyset$ , degree 1) plus four mutant rejections (tightened goal, wrong dynamics sign, degree lie, sub-dimensional simplex) and the nonconvex-predicate rejection. Downstream, the same chain carries the checker to a CakeML binary with the machine\_code\_sound tag (theory bernCertProofARM8). bernConeIntvCheck is the ported companion of a since-retired validated-numeric rule variant; its round-down-then-check strategy is destined to fold into the BernCone checker as an internal fast path (evaluation strategy, not proof content), and the ported definition with its three receipt rows (exact-dyadic accept, rounded-bound accept, non-representable-bound reject) is retained as that branch's reference. Semantic stratum, also ported: the soundness twins sound\_bernCone and its  $S = \emptyset$  specialization sound\_bernCone\_empty (theory bern\_tr\_berncone: hol-strict clean, 14 theorems, 0 offences, verification run of 2026-07-22 on an isolated build host, content-addressed at the same sources), consumed by the certified-fragment keystone (checkPf\_sound\_frag, theory bern\_tr\_splice, 20 theorems, 0 offences, same run) under the payload's decode-time gates: a reference-checker accept inside the proven wire fragment yields sequent validity.

HOL receipts are documentary: quoted results of hol-strict runs and census rows from the HOL4 development's build evidence, not minted receipt artefacts. A HOL receipt store (the Lean store's twin) is named future work.

## Proof

Genre: core rule (tier 1) — an ordinary mathematical proof at Putnam-exam-solution detail. Every hypothesis of the rule is used below and remarked on, with the counterexample its removal admits where one exists; the formal-anchor table maps each step to the Lean declaration that carries it.

**Setting and claim.** Fix a hypernet  $H$ . A valuation  $\sigma$  assigns each wire a rational tensor of its declared shape; a sequent  $\Phi \vdash \Psi$  is semantically valid when every admissible  $\sigma$  satisfying  $\Phi$  satisfies  $\Psi$ , with comparison atoms read per-entry. A region atom  $x \in \mathcal{R}(\Delta, S)$ , for  $\Delta = \text{conv}(V_0, \dots, V_n)$  an  $n$ -simplex and  $S \subsetneq \{0, \dots, n\}$  a proper set of *extended* vertices, holds at  $\sigma$  when the evaluated point admits barycentric weights  $\lambda_v$  with  $\sum_v \lambda_v = 1$ ,  $\lambda_v \geq 0$  at core vertices  $v \notin S$ , and  $\lambda_v \leq 0$  at  $v \in S$  — the closed simplex when  $S = \emptyset$ , and the unbounded set extending beyond the faces opposite  $S$  otherwise. (Field bookkeeping, fixed once: the vertices  $V_0, \dots, V_n$  are exact rational data of the payload; the weights  $\lambda_v$  are quantified over  $\mathbb{R}$ ; and the evaluated point is rational, valuations assigning rational tensors — Step 2 of the theorem is where these three facts meet.) The rule's payload supplies the region premise  $\Phi \vdash x \in \mathcal{R}(\Delta, S)$ , a polynomial term  $p$  of degree  $\leq d$ , a predicate  $P$  from the accepted grammar (a finite conjunction of scalar hole-atoms  $s \cdot \square \bowtie c$ ,  $s > 0$ ,  $\bowtie \in \{\leq, \geq, =\}$ ), the checked wire tie polyTie, the predicate-shape clause ( $P$  conic when  $S \neq \emptyset$ ; convex suffices when  $S = \emptyset$ ), and the checked coefficient condition: every forward-difference Bernstein coefficient of  $p$  over  $\mathcal{R}(\Delta, S)$ , recomputed exactly, satisfies  $P$ . For  $S \neq \emptyset$  the checker's scope guard is part of the rule's acceptance: certificates are confined to constant canonical forms (any dimension) or single-wire polynomials over a 1-dimensional region (**Remark R15.8**) — “accepted” below always means guard-passing. The claim (sound\_bernCone): the composite sequent  $\Phi \vdash P(p(x))$  is then semantically valid.

**Lemma R15.1** (Bernstein form on the closed simplex). *Let  $p$  be a polynomial of degree  $\leq d$  on  $\mathbb{R}^n$  with degree- $d$  Bernstein coefficients  $(b_\alpha)_{|\alpha|=d}$  on  $\Delta$ , so that  $p(x) = \sum_{|\alpha|=d} b_\alpha B_\alpha^d(\lambda)$  with  $B_\alpha^d(\lambda) = \binom{d}{\alpha} \lambda^\alpha$  in the barycentric coordinates  $\lambda$  of  $x$ . For  $x \in \Delta$  (all  $\lambda_v \geq 0$ ),*

$$B_\alpha^d(\lambda) \geq 0 \quad \text{and} \quad \sum_{|\alpha|=d} B_\alpha^d(\lambda) = \left( \sum_v \lambda_v \right)^d = 1,$$

*so  $p(x)$  is a convex combination of the coefficients  $b_\alpha$ .*

*Proof.* Nonnegativity is termwise ( $\lambda^\alpha \geq 0$ ); the partition of unity is the multinomial theorem applied to  $(\lambda_0 + \dots + \lambda_n)^d = 1^d$ . The representation itself is the classical change to the Bernstein basis [18, 74]; the checker *computes* the  $b_\alpha$  from  $p$ 's canonical monomial form by exact forward differencing over  $\mathbb{Q}$ , so the representation is an identity of exact rational data, not an approximation. That Bernstein coefficients enclose the range of  $p$  on  $\Delta$  — the reading of this lemma used below — is the sound (easy) direction of [39].  $\square$

**Lemma R15.2** (accepted predicates are convex). *Let  $P$  be accepted by the predicate classifier. Then its satisfaction set  $\{v \in \mathbb{Q} : \text{satisfiesPredQ}(P, v)\}$  is convex.*

*Proof.* Each accepted atom orients (possibly by mirroring) to  $s \cdot v \bowtie c$  with  $s > 0$  and  $\bowtie \in \{\leq, \geq, =\}$ ; its satisfaction set is a closed ray or a point — an interval either way — and division by the positive  $s$  does not disturb this. A conjunction intersects finitely many intervals. Strict comparators and  $\neq$  are *refused* by the classifier — closed-world conservatism that can lose completeness but never soundness; the refusal is a checker verdict, not a soundness case.  $\square$

**Lemma R15.3** (the univariate ray identity). *Let  $d \geq 0$  and let  $b_0, \dots, b_d$  be the degree- $d$  Bernstein coefficients of  $p$  on the segment  $[V_a, V_b]$ , indexed by the multiplicity of  $V_b$  (labels chosen so that the extended vertex is  $V_a$  and the core vertex is  $V_b$ ; the mirrored case relabels — concretely, with the other vertex extended, apply the identity to the reversed sequence  $c_i := b_{d-i}$ , whose differences against the un-reversed one are the signed  $(\Delta^j c)_{d-j} = (-1)^j (\Delta^j b)_0$ ; the checked table is computed relative to the extension mask, so its rows are the  $(\Delta^j c)_{d-j}$  of the relabeled orientation). Let  $x$  lie on the extension ray beyond  $V_b$ : in barycentric coordinates  $x = \lambda_a V_a + \lambda_b V_b$  with  $\lambda_a = -u \leq 0$ ,  $\lambda_b = 1 + u$ ,  $u \geq 0$ . Then, with  $(\Delta b)_i := b_{i+1} - b_i$  the forward difference,*

$$p(x) = \sum_{j=0}^d \binom{d}{j} u^j (\Delta^j b)_{d-j}, \quad (*)$$

a combination of the certified table values  $(\Delta^j b)_{d-j}$  with nonnegative weights  $\binom{d}{j} u^j$ , the  $j = 0$  weight being 1.

*Proof.* Substitute  $\lambda_a = -u$ ,  $\lambda_b = 1 + u$  into the Bernstein form and expand  $(1 + u)^i$  binomially:

$$p(x) = \sum_{i=0}^d \binom{d}{i} b_i (-u)^{d-i} (1 + u)^i = \sum_{i=0}^d \sum_{k=0}^i \binom{d}{i} \binom{i}{k} (-1)^{d-i} b_i u^{d-i+k}.$$

Collect the coefficient of  $u^j$ : setting  $i = d - j + m$  with  $m = 0, \dots, j$ , it is  $\sum_{m=0}^j \binom{d}{d-j+m} \binom{d-j+m}{m} (-1)^{j-m} b_{d-j+m}$ . The product of binomials telescopes,

$$\binom{d}{d-j+m} \binom{d-j+m}{m} = \frac{d!}{(j-m)! m! (d-j)!} = \binom{d}{j} \binom{j}{m},$$

so the coefficient of  $u^j$  is  $\binom{d}{j} \sum_{m=0}^j \binom{j}{m} (-1)^{j-m} b_{d-j+m} = \binom{d}{j} (\Delta^j b)_{d-j}$ , which is  $(*)$ . (Degree-1 sanity check:  $p(x) = b_1 + u(b_1 - b_0)$ , matching  $(1 + u)b_1 - ub_0$  directly.) The values  $(\Delta^j b)_{d-j}$  are exactly the rows the checker's forward-difference table certifies on this fragment: the  $j$ -th difference of the coefficient sequence, anchored at the core vertex — in the rule display's notation, the degree- $d$  Bernstein coefficients of the difference polynomials  $P_j$  on the core face  $F_S$ , specialized to the one-dimensional and constant shapes the scope guard admits.  $\square$

**Lemma R15.4** (conic transfer). *Let  $P$  be accepted with the conic classification (every atom's constant is 0). Then its satisfaction set contains 0, and is closed under nonnegative scaling and under finite nonnegative combinations.*

*Proof.* Each conic atom reads  $s \cdot v \bowtie 0$ , satisfied at  $v = 0$  and preserved under  $v \mapsto tv$  for  $t \geq 0$ ; conjunction preserves both facts. Closure under addition follows from convexity (Lemma R15.2) plus scaling:  $v + w = 2 \cdot \frac{1}{2}(v + w)$ ; induction extends to finite nonnegative combinations.  $\square$

**Theorem R15.5** (soundness of BERNCONe). *Under the payload's checked hypotheses, if the region premise is semantically valid, then so is  $\Phi \vdash P(p(x))$ .*

*Proof.* Fix an admissible  $\sigma \models \Phi$ ; the region premise yields barycentric weights for the evaluated point of  $x$  as in the Setting. The conclusion formula is, by the checked `postApply`, the predicate  $P$  with the polynomial term substituted for its hole, so it suffices to establish `satisfiesPredQ`( $P, \cdot$ ) at the evaluated value(s) of  $p$  — per-entry, when  $p$  is tensor-shaped.

*Step 1 (the polynomial reads one point).* The wire tie `polyTie` says  $p$  is closed, or mentions exactly the region wire  $w$  with  $x = w$ . In the second case the region premise pins  $\sigma$ 's read of  $w$  to a point of  $\mathcal{R}(\Delta, S)$ ; in the first, no wire is read at all and  $p$ 's value is its closed constant.

*Step 2 (rational weights).* The model's barycentric weights are *real*; the kernel computes over  $\mathbb{Q}$ . The weights solve a linear system with rational data (the vertex coordinates and the evaluated point) under the region atom's sign pattern —  $\lambda_v \geq 0$  at core vertices,  $\lambda_v \leq 0$  at extended ones. Substituting  $\mu_v := -\lambda_v$  at the extended vertices turns the pattern into a nonnegative-orthant condition on a rational polyhedron, so a real solution can be traded for a rational one with the same signs, and the exact kernel consumes the rational weights. This step is invisible in informal treatments and load-bearing in the mechanization.

*Step 3 (case  $S = \emptyset$ : the convex kernel).* By Lemma R15.1,  $p$ 's value is a convex combination of the certified coefficients; every coefficient satisfies  $P$  (the checked table sweep); by Lemma R15.2 satisfaction transfers to the combination. On this case the

checker admits both translation routes — the idx-free single-wire form and the multivariate projection-indexed form with all indices in range — and the per-entry evaluation lemma carries the scalar argument to every entry of a tensor-shaped value.

*Step 4 (case  $S \neq \emptyset$ ).* The checker’s scope guard confines accepted certificates to two shapes. (4a: *constant canonical form, any dimension.*) If  $p$ ’s canonical polynomial has no variables, its value everywhere is the constant — the zero-order forward-difference row is that constant, certified directly. (4b: *single-wire polynomial over a 1-dimensional region.*) A proper nonempty extension set on a 1-simplex extends exactly one of the two vertices, and  $\mathcal{R}(\Delta, S)$  is the closed ray from the core vertex; Lemma R15.3 writes  $p$ ’s value as a nonnegative combination of the certified table values with the  $j = 0$  weight equal to 1, and Lemma R15.4 transfers satisfaction through the combination. Everything else is *refused* by the guard, so no further case exists for soundness to cover.

*Step 5 (read off).* In each case  $\text{satisfiesPredQ}(P, \cdot)$  holds at the evaluated value; the substitution reading turns this into  $\sigma \models P(p(x))$ .  $\square$

*Remark R15.6 (why polyTie is not decoration).* Nothing else ties the checked polynomial to the wire the premise constrains. Without the field, take the satisfiable premise  $w_0 \in \mathcal{R}(\text{conv}(1, 2), \emptyset)$  and the polynomial  $p = w_1$  over a *different* wire: the translation remaps the single-variable canonical form onto the region coordinate, the certified coefficients are  $\{1, 2\}$  — both satisfying  $\square \geq 1$  — and the rule would conclude  $\Phi \vdash w_1 \geq 1$ , false at any valuation reading  $\sigma(w_1) = 0$ . Closed polynomials need no tie: their value reads no wire.

*Remark R15.7 (why conic, not merely convex, on rays).* The predicate-shape clause is two-sided because the two region shapes transfer differently: convex combinations (Lemma R15.1) on the closed simplex, conic combinations with unbounded weights ( $\star$ ) on a ray. A convex-but-not-conic predicate fails on the ray, by hand: take  $d = 1$ ,  $\Delta = \text{conv}(0, 1)$  with the vertex at 0 extended (the region is the ray  $[1, \infty)$ ),  $p(t) = 1 - t$ , and  $P = (\square \geq -1)$ . The certified table is  $\{b_1, (\Delta b)_0\} = \{0, -1\}$ , every value satisfying  $P$ ; yet at  $u = 2$  (the point  $t = 3$ ), ( $\star$ ) gives  $p = b_1 + 2(b_1 - b_0) = -2 < -1$ . The classifier refuses exactly this: an atom with nonzero constant classifies non-conic, and the  $S \neq \emptyset$  clause then rejects the certificate. Conversely, at  $S = \emptyset$  demanding conic would be needless strength — the rule carries the license (any accepted convex predicate) in the premise itself rather than in surrounding prose.

*Remark R15.8 (the scope guard is part of the theorem).* The checker refuses non-constant idx-free polynomials over regions of dimension  $\neq 1$ , and multivariate projection-indexed polynomials whenever  $S \neq \emptyset$ . Soundness is stated and proven for every certificate the checker *accepts*; the guard makes the unproven territory unrepresentable rather than discouraged. The fully general multivariate ray identity (the arbitrary-shape analogue of Lemma R15.3) remains open in the development and becomes load-bearing only if the guard lifts — the two must move together.

*Remark R15.9 (relation to the literature).* The rule is the certificate form of Bernstein-coefficient range enclosure: coefficients bound the range on the simplex [39], enclosures converge under degree elevation and subdivision [85] — which is why SUBDIVIDE is this rule’s completeness partner — and the basis itself goes back to [18], surveyed in [74]. With polynomial atoms and positivity certificates the rule sits beside the Krivine–Handelman family [110, 144]: as everywhere in this calculus, only the trivial (sound) direction is claimed or needed — no Positivstellensatz completeness enters the kernel. The forward-difference computation of the coefficient table is the classical finite-difference reading of the Bernstein form; the subdivision algorithms of [40, 151] operate on the same data one rule over.

| proof step                                                                            | formal anchor                                                                                                                                                                                   |

## 15.3 Admissible and Alias Rules

### Rule 16. NORM (admissible rule)

#### The rule (Steele metanotation)

as realized in the mechanized development; source row: `rules.toml` — *Norm*. The metanotation statement is typeset by hand for notational quality; its mechanized ground truth is the Lean statement below, extracted from the sources at every build of this book and hash-bound. The rule *roster* is machine-checked (every mechanized rule tag round-trips to exactly one catalogue row); the statement *text* is editorial, checked by eye against the extracted Lean beside it.

$$\frac{t_1, t_2 \text{ polynomial terms in the same variables with equal monomial canonical forms over } \mathbb{Q} \quad \text{bshape}_H(t_1) = \text{bshape}_H(t_2) \neq \perp \text{ (a shared defined broadcast shape)} \quad \text{wires}(t_1), \text{wires}(t_2) \text{ all finitely typed in } H}{\Phi \vdash t_1 = t_2} \text{ NORM}$$

NORM is the calculus's computation rule: it states, as a premise-free sequent, every equality of polynomial terms that holds by *canonical form* —  $w + w = 2 \cdot w$ , distributivity, collection of like monomials, exact  $\mathbb{Q}$  coefficient arithmetic. A producer uses it constantly and invisibly: whenever an emitted derivation needs two spellings of the same polynomial to be interchangeable (before an EQELIM, to massage a term into the pinned shape another rule's payload demands), a single NORM node discharges the rewriting that an equational-logic presentation would smear across many congruence steps.

What the checker recomputes: that both sides are idx-free (projection terms have no canonical form in the wire-keyed polynomial space — the comparison would not carry the rule's meaning), and that the two canonical polynomials are *identical* — coefficient-for-coefficient equality over  $\mathbb{Q}$ , never evaluation at test points, and never rescaling:  $2 \cdot w$  and  $w + w$  are equal as canonical forms;  $2 \cdot w$  and  $w$  are not, proportional though they are. The remaining payload fields are well-typedness, not computation: both sides share a defined broadcast shape and mention only finitely typed wires.

Each hypothesis is load-bearing. Drop the canonical-form identity and the rule asserts arbitrary equalities. Drop the shared-shape and finiteness fields and the rule is false *as staged*: at a wire of extended dtype, even  $\vdash t = t$  is invalid — the atom fails to hold at every valuation giving the wire an infinite entry, while holding at the rational ones — and since the premise is arbitrary, the staged rule concluded failing sequents from satisfiable premises; a cancelling sub-term  $w_2 - w_2$  over a wire whose shape does not join with the other side's leaves the same canonical form but an atom that never evaluates at any valuation — unsatisfiable outright. The typing fields are exactly what makes “equal canonical forms” imply “equal evaluated tensors” at every valuation.

**notes** The rule also names a convention the premise-free rules of this catalogue share (*the NORM convention*): the premise  $\Phi$  is arbitrary and never consulted — a fact that holds at every valuation holds under any premise. The catalogued stratum records an unpacking sketch through BERNONE and ARITHATOM; the shipped warrant is direct and stronger (one verified semantic lemma, all tensor shapes), with the well-typedness fields carrying what the sketch left implicit.

#### Lean statement

BernsteinLogic.Soundness . sound\_norm

statement bound

```
-- Norm, sound under the PROPOSED-B13-Norm fields: both sides evaluate
(bshape + finWires), at the same shape (`tyEq` + `evalQ_bshape`), with
per-entry values equal because the canonical polynomials are literally
equal. -/
theorem sound_norm {H : Hypernet} {seq : Sequent} {termL termR : Term}
  (hcanon : polynomialCanonicalEq termL termR)
  (htyEq : termL.bshape H = termR.bshape H)
  (htyDef : ∃ s, termL.bshape H = some s)
  (hfinL : termL.finWires H) (hfinR : termR.finWires H)
  (hpost : seq.post = .atom .eq termL termR) :
  seq.semanticallyValid H
```

**The whole computational content, displayed.** The check is two gates and one equality: both sides idx-free, and the canonical polynomials literally equal. Everything else the rule needs is well-typedness data carried in the payload and consumed by the soundness lemma, not by the checker.

BernsteinLogic.Core.Catalogue . Term.toPoly

## Correspondence (Steele display ↔ Lean)

reviewer-certified against the displayed texts

The dictionary below is a reviewer-certified statement of how the mechanized statements above interpret the displayed rule: display metavariable  $\mapsto$  Lean binder, each display hypothesis  $\mapsto$  the premise or side condition carrying it, the display conclusion  $\mapsto$  the goal — with any deliberate difference in width between display and mechanization named outright. Certification is recorded as a hash triple over (the displayed cell, the extracted statement texts, this dictionary's own text); if any of the three changes, this block turns amber until a reviewer re-certifies. The correspondence claim itself remains editorial — reviewer-grade, not machine-checked; its machine-checked successor types each soundness statement against the rule as a structured object, and supersedes this block per rule as it lands.

Judgment frame as in Ax.

- $t_1, t_2 \mapsto \text{termL termR} : \text{Term}$ ; the displayed side condition (equal monomial canonical forms)  $\mapsto \text{hcanon} : \text{polynomialCanonicalEq termL termR}$ , quoted in full below — both sides idx-free and the canonical polynomials literally equal. The display's "same variables" and "polynomial terms" have no separate binders: canonical forms are wire-keyed (equality forces the same canonical support — a mentioned-but-cancelled wire is no constraint on the polynomial; evaluability polices it through the typing fields instead) and the term grammar is polynomial by construction.
- conclusion  $\Phi \vdash t_1 = t_2 \mapsto$  the goal under  $\text{hpost} : \text{seq.post} = \text{.atom .eq termL termR}$ ; the arbitrary  $\Phi$  is premise-freeness by silence — the precondition component of  $\text{seq} : \text{Sequent}$  is unconstrained by any hypothesis (the  $\text{PConstExact}$  representation).

Width note: the display carries the typing pack inline, matching the mechanized statement's four well-typedness hypotheses one for one —  $\text{htyEq}$  (both broadcast shapes equal),  $\text{htyDef}$  (and defined — the some),  $\text{hfinL}/\text{hfinR}$  (all free wires at finite dtypes). The bound  $\text{PNormData}$  payload carries the same conditions under its own field names —  $\text{hcanon} \leftrightarrow \text{canonEq}$ ,  $\text{htyEq} \leftrightarrow \text{tyEq}$ ,  $\text{htyDef} \leftrightarrow \text{tyDef}$ ,  $\text{hfinL}/\text{hfinR} \leftrightarrow \text{finL}/\text{finR}$ ,  $\text{hpost} \leftrightarrow \text{postEq}$  — and they are not optional: without them the bare canonical-form rule is refuted (an  $\infty$ -valued wire makes even  $t = t$  fail at every extended-valued assignment — the roster row's counterexample). The one-line canonical-form sentence is the rule's *intent*; the certified statement is that sentence plus exactly this typing pack.

## Lean verifier receipts

module BernsteinLogic.Soundness; bound build a20d90e66c13... (bound from receipt a9c0e34d3e3c9c8c, 2026-08-03T21:30:36Z). A receipt records that named checking layers accepted a build: (module, compiled-artifact SHA-256, environment SHA-256, checker layers), minted when the checking gate ran; the store receipts attesting the bound build are listed with the layers each run credited. Nothing here asks the reader to trust the store: every layer is an independently runnable program over the quoted sources — rebuild the module and re-run the checkers to reproduce the verdict. Receipts attesting superseded builds credit no layer and are omitted from this rendering (the count of omissions, if any, is noted below).

| receipt          | minted               | layers             | status  |
|------------------|----------------------|--------------------|---------|
| a9c0e34d3e3c9c8c | 2026-08-03T21:30:36Z | build+decorrelated | current |

21 further receipt(s) in the store attest superseded builds of this module and are omitted from this rendering.

module BernsteinLogic.Core.Catalogue; bound build cbc92e976a1d... (bound from receipt 5abdb3589707b5df, 2026-08-03T21:30:33Z). A receipt records that named checking layers accepted a build: (module, compiled-artifact SHA-256, environment SHA-256, checker layers), minted when the checking gate ran; the store receipts attesting the bound build are listed with the layers each run credited. Nothing here asks the reader to trust the store: every layer is an independently runnable program over the quoted sources — rebuild the module and re-run the checkers to reproduce the verdict. Receipts attesting superseded builds credit no layer and are omitted from this rendering (the count of omissions, if any, is noted below).

#### gate-layer coverage of the bound build:

build (lake build (elaboration)) current

replay (leanchecker (official kernel replay)) stale only

hardened (safe\_verify (hardened screen)) stale only

decorrelated (lean4export + nanoda (decorrelated kernel)) current

comparator: fixture NormOutsideFragment the three-implementation comparator harness (compiled machine code, kernel-reduction probes, and the compiler-IR interpreter, all executing the same elaborated checker functions) carries a well-typed single NORM node as its fixture NormOutsideFragment, expected verdicts check = true, v0frag = false. The fixture is the suite's false-verdict control: NORM sits outside the restricted fragment recognizer by design, so the fixture pins the reject lane end to end — a comparator that could only confirm acceptance would be blind to a path that wrongly accepts everything.

## HOL4 statement

theory bern\_catalogue, HOL4 development script bern\_catalogueScript.sml script bound

    termIdxFree l ∧ termIdxFree r ∧ termToPoly l = termToPoly r
End
```

## HOL verifier receipts

documentary hol-strict CLEAN over the ported checker chain: theory bern\_catalogue, 472 theorems, 0 cheat-tagged, 0 nonstandard axioms (whitelist: DISK\_THM; the four bool axioms) — verification run of 2026-07-22 on an isolated build host, scripts sha-matched verbatim to the sources cited here (git blob e41b9ed0...). The ported receipt table pins the rule's exactness discipline in both directions: the canonical-form accept ( $w_0 + w_0 = 2 \cdot w_0$ ) and the scale-preserving reject ( $2 \cdot w_0 \neq w_0$  as canonical forms). Scope note, honest by the port's own seam inventory: the ported surface is the first-order check function; the payload's well-typedness fields (broadcast shapes, finite typing) live in the dependently-typed proof-object layer, which is a separately tracked porting stage. Semantic stratum, also ported: the soundness twin sound\_norm (theory bern\_tr\_fragclose: hol-strict clean, 26 theorems, 0 offences, verification run of 2026-07-22 on an isolated build host, content-addressed at the same sources), consumed by the certified-fragment keystone (checkPf\_sound\_frag, theory bern\_tr\_splce, 20 theorems, 0 offences, same run): a reference-checker accept inside the proven wire fragment yields sequent validity.

HOL receipts are documentary: quoted results of hol-strict runs and census rows from the HOL4 development's build evidence, not minted receipt artefacts. A HOL receipt store (the Lean store's twin) is named future work.

## Proof

Genre: admissible rule (tier 2) — a proof-tree-rewriting recipe. The tier taxonomy defines tier 2 as *verified unpacking into core rules* (one node → many), with rules admissible by *reduction to verified machinery* as the recorded boundary case; NORM is of the latter kind, and this section — the book's first admissible rule — states the general template that the later recipes instantiate.

**Recipe R16.1** (the admissible template, general form). An admissible rule  $R$  with premises  $P_1, \dots, P_n$  and conclusion  $C$  is warranted by a *rewrite*: a function taking any proof-tree node

$$\frac{\mathcal{T}_1 \triangleright P_1 \quad \cdots \quad \mathcal{T}_n \triangleright P_n}{C} R \quad \rightsquigarrow \quad \mathcal{D}[\mathcal{T}_1, \dots, \mathcal{T}_n] \triangleright C$$

where  $\mathcal{D}$  is a derivation fragment over core (and previously-justified admissible) rules with the same conclusion, consuming the premise subtrees  $\mathcal{T}_i$  at its leaves. Where such a fragment exists, applying it leaf-first eliminates every  $R$ -node from a finite tree in

finitely many steps, so any judgment derivable with  $R$  is derivable without it — admissibility in the derivability sense. In the tier’s recorded boundary case — rules admissible *by reduction to verified machinery*, this one among them — no fragment is applied: where no catalogue derivation of  $C$  can exist, the node is instead discharged in place against a named verified theorem, no derivability claim is made, and the conserved property — weaker, and sufficient — is the calculus’s soundness theorem itself. Either way, no new kernel semantic content enters. The verified object shipped per admissible rule is a soundness lemma for  $R$  that factors through already-verified machinery: for a fragment-backed rule, provable by replaying  $\mathcal{D}$ ; for a boundary-case rule, the discharge theorem itself.

**Recipe R16.2** (the NORM instance — the degenerate rewrite). NORM has no proof premises ( $n = 0$ ): the node

$$\frac{\text{polynomialCanonicalEq}(t_1, t_2) \quad \text{both sides shape-stable and finitely typed}}{\Phi \vdash t_1 = t_2} \text{NORM} \rightsquigarrow \text{the checker replays the canonical forms; sound\_no}$$

The side condition is *computational*: both sides idx-free, and their canonical monomial polynomials *identical* over  $\mathbb{Q}$  — coefficient-for-coefficient, decidable, replayed by the checker. The catalogued stratum records an unpacking sketch through `BERNCONE` and `ARITHATOM` (an equality as a pair of zero-polynomial bounds); the shipped warrant is direct and stronger — one verified semantic lemma at all tensor shapes — with the payload’s well-typedness fields carrying exactly what the sketch left implicit.

**Proposition R16.3** (semantic warrant). *Suppose  $t_1, t_2$  are idx-free with  $t_1.\text{toPoly} = t_2.\text{toPoly}$ , the two sides carry the same defined broadcast shape in  $H$ , and every wire of either side is finitely typed. Then  $\Phi \vdash t_1 = t_2$  is semantically valid over  $H$  for arbitrary  $\Phi$ .*

*Proof.* Fix any admissible valuation  $\sigma$ ; the premise is not consulted — this is *the NORM convention*, shared by every premise-free rule of the catalogue: a fact holding at every valuation holds under any premise. The shape and finiteness fields give both sides defined evaluations, as tensors of the common broadcast shape  $s$ : a term’s broadcast shape is computed structurally, so its definedness already certifies that every subterm’s join exists; finitely typed wires always read; and idx-freedom leaves no projection to fail. If  $s$  has positive rank and zero total size, both sides evaluate to the unique empty tensor of shape  $s$  and the equality atom holds outright — there is no entry to compare. Otherwise fix an entry index of  $s$  (for  $s = []$ , the single scalar position) and read each wire at it: a rank-0 wire contributes its scalar, and a positive-rank wire — necessarily of shape  $s$  itself, the only positive rank that joins with  $s$  under this broadcast discipline — contributes its entry at the index. Evaluation at that read-out is a ring homomorphism into  $\mathbb{Q}$  from the polynomial ring over the union of the wires the two sides mention (a wire absent from one side, or cancelled from its canonical form, simply carries coefficient zero there); a syntactic identity of canonical forms is an identity of polynomials, and ring homomorphisms preserve polynomial identities — so the two evaluated tensors agree entry by entry, and their shapes agree by hypothesis. Hence the equality atom holds at  $\sigma$ . That is the whole proof; `sound_norm` packages it once, per-entry, at every tensor shape.  $\square$

**Remark R16.4** (what broke without the typing fields). As first staged — canonical-form equality alone — the rule was *false*, twice over, and the counterexamples are why the fields exist. (i) At a wire of extended dtype, the staged rule concluded *invalid* sequents: at any valuation giving the wire an infinite entry, even  $t = t$  fails to hold — evaluation is over exact rationals, and an infinite entry refuses — so  $\vdash t = t$  fails exactly at the extended-valued assignments while holding at the rational ones. (ii) A cancelling sub-term leaves the canonical form unchanged but not the evaluation:  $t_2 = t_1 + (w_2 - w_2)$  has  $t_2.\text{toPoly} = t_1.\text{toPoly}$ , yet if  $w_2$ ’s shape does not join with  $t_1$ ’s, the right-hand atom side never evaluates at *any* valuation — there the concluded atom is unsatisfiable outright. In either case a satisfiable (indeed arbitrary) premise concluded a failing sequent; the shared-shape and finiteness fields exclude both. A hypothesis whose necessity is semantic (evaluability), not algebraic, is exactly the kind a recipe must state, or the next porter re-learns it the hard way.

**Remark R16.5** (exactness discipline, and the idx-freedom gate). Canonical-form equality is never up-to-rescaling:  $2 \cdot w$  and  $w + w$  are equal as canonical forms;  $2 \cdot w$  and  $w$  are not, proportional though they are — the matching discipline every combination rule of this catalogue (`FARKAS`, `SZYGY`) inherits when it compares atom polynomials. The idx-freedom gate is the meaning-preservation condition of the translation: the wire-keyed polynomial space cannot express per-entry projections, so a projection-bearing term has no canonical form here and the comparison is refused rather than performed on the wrong object. (The combination rules’ widened replays translate projections into their own variable spaces; those translations belong to those rules, not to NORM.)

## Rule 17. FARKAS (admissible rule)

### The rule (Steele metanotation)

as realized in the mechanized development; source row: `rules.toml` — *Farkas*. The metanotation statement is typeset by hand for notational quality; its mechanized ground truth is the Lean statement below, extracted from the sources at every build of this book and hash-bound. The rule *roster* is machine-checked (every mechanized rule tag round-trips to exactly one catalogue row); the statement *text* is editorial, checked by eye against the extracted Lean beside it.

$$\frac{\begin{array}{l} \{\ell_j \bowtie_j 0\}_j \text{ a sub-conjunction of } \Phi \text{ with each } \ell_j \text{ linear, } \bowtie_j \in \{\leq, =\} \\ \{\lambda_j \in \mathbb{Q}_{\geq 0}\}_j \text{ nonneg coefficients, with } \lambda_j \text{ free when } \bowtie_j \text{ is } = \\ \text{wires}(\sum_j \lambda_j \ell_j) \text{ all finitely typed in } H \end{array}}{\Phi \vdash \sum_j \lambda_j \ell_j \leq 0} \text{ FARKAS}$$

FARKAS is the affine-combination rule over the premise: from atoms  $\{\ell_j \bowtie_j 0\}$  occurring as sub-conjuncts of  $\Phi$  and nonnegative multipliers  $\lambda_j$  (free-signed on equality atoms), it concludes  $\Phi \vdash \sum_j \lambda_j \ell_j \leq 0$ . It is the one-rule form of what SYZVGV does with sub-*proofs*: here every combined atom must already sit in the premise conjunction, so no component derivations enter. A producer finds the multipliers by whatever method it likes (an LP feasibility call, typically) and ships only the combination term; nothing about the search survives into the certificate.

What the checker recomputes, given the payload (combination term, conclusion term): decode the combination into weighted entries — a fixed canonical encoding (a right-nested sum of  $\lambda_j \cdot e_j$  products with a zero terminator), anything else rejected; require each weight nonnegative; require each entry's polynomial to occur among the  $(\cdot \leq 0)$ -normal polynomials of a premise conjunct — equality atoms expose *both* polarities to the matcher, which is exactly how a free-sign multiplier on an equality is realized as a nonnegative weight on the appropriate polarity; and require the weighted fold of the entry polynomials to equal the conclusion's polynomial *identically*, as canonical forms over  $\mathbb{Q}$ . The check is a disjunction of three branches of one replay algorithm, differing only in the variable space where polynomials are compared: the legacy idx-free canonical-form branch, a wire-aware coordinate branch for projection-indexed terms, and a mixed tagged-union branch for combinations mentioning both bare wires and projections.

Each hypothesis is load-bearing. Drop the sign condition and a producer multiplies a bound by  $-1$  and concludes its negation. Drop the atom-sourcing check and the combination smuggles in atoms nobody assumed. Drop the exact fold identity and the conclusion is unrelated to the premise. Drop the positive-size wire condition and the rule is unsound at degenerate shapes: comparison atoms over a zero-size (empty-tensor) wire hold *vacuously*, and a combination of two vacuous contradictory atoms —  $5 \leq w$  and  $w \leq 3$  at a wire of shape  $[0]$  — derives the false scalar conclusion  $\vdash 2 \leq 0$  from a satisfiable premise. Drop the conclusion's shape/finiteness fields and a conclusion mentioning an untyped wire has a correct canonical polynomial but never evaluates, so the concluded atom never holds. The proof section walks these in order.

**notes** The catalogued statement ranges over *linear*  $\ell_j$ ; the replay itself is degree-blind, and soundness never consults linearity — the restriction is the rule's published register (the shape producers emit and the wire format prices), not a checked side condition. SYZVGV lifts the same fold to component conclusions with degrees unrestricted; PBOUND re-spells that lift as the compact affine bound-node.

  seq.semanticallyValid H

```

**What the combination check means — and what it does not.** The side condition appears in the payload as the single name `farkasCombinationValid`, so this book binds its meaning by displaying the decoding chain from the checker sources. `farkasEntries` decodes the combination term against a *pinned* canonical encoding — anything else is rejected, so the wire format cannot express a malformed combination. `atomLeZeroPolys` is the  $(\cdot \leq 0)$ -normalization of one premise atom, exact and never rescaled; note that equality atoms contribute both polarities, which is the entire realization of the classical free-sign multiplier discipline for equality constraints. `farkasCheckCore` strings the gates together in the `idx`-free canonical-form space; `farkasCheck` is the three-way branch disjunction — the two widened branches replay the same gates verbatim in the wire-aware coordinate space (projection terms  $w[j]$  keyed by an injective pairing of wire and coordinate, so distinct wires can never collide) and in the mixed tagged-union space (bare wires and projections as disjoint variable classes; the variant identifying a bare wire with its zeroth projection admits a false sequent and is deliberately unrepresentable).

What a skeptical reader should confirm by eye: the conclusion term enters only as the target of the exact fold identity; the step's posted formula appears nowhere in the check; and nothing in the chain evaluates or consults the truth of anything — the check manipulates polynomials, never valuations. Semantic truth is established only in `sound_farkas`, which case-splits on the accepted branch.

## Correspondence (Steele display $\leftrightarrow$ Lean)

**a bound Lean statement CHANGED since certification — re-review and re-certify** The dictionary below is a reviewer-certified statement of how the mechanized statements above interpret the displayed rule: display metavariable  $\mapsto$  Lean binder, each display hypothesis  $\mapsto$  the premise or side condition carrying it, the display conclusion  $\mapsto$  the goal — with any deliberate difference in width between display and mechanization named outright. Certification is recorded as a hash triple over (the displayed cell, the extracted statement texts, this dictionary's own text); if any of the three changes, this block turns amber until a reviewer re-certifies. The correspondence claim itself remains editorial — reviewer-grade, not machine-checked; its machine-checked successor types each soundness statement against the rule as a structured object, and supersedes this block per rule as it lands.

Judgment frame as in Ax. Distinctively, there is no sub-derivation hypothesis at all: the displayed premise row describes the syntactic conjunct structure of  $\Phi$  itself, so the statement consumes `seq.pre` directly and no `ih` exists.

- the combination  $\sum_j \lambda_j \ell_j \mapsto$  the binder conclusion : Term; the multipliers  $\lambda_j \mapsto$  encoded in `combinationCoeffs` : Term under the pinned canonical encoding the intro describes.
- the displayed premise row — sub-conjunction of  $\Phi$ , each  $\ell_j$  linear,  $\bowtie_j \in \{\leq, =\}$ , multipliers nonnegative and free exactly on equalities, and the identity of conclusion with the combination  $\mapsto$  one hypothesis, `hvalid` : `farkasCombinationValid combinationCoeffs seq.pre conclusion`, whose meaning this book binds by displaying the decoding chain in full (absorbed hypotheses, the PCONSTEXACT pattern: a successful check certifies the structure; the free-sign discipline is realized as both-polarity contribution of equality atoms). The displayed row is the rule's published register; the realized matcher is wider — see the width note below.
- the displayed typing premises  $\text{bshape}_H(\sum \lambda_j \ell_j) \neq \perp$  and finite typing  $\mapsto$  `hshape` (existence of a defined broadcast shape — the some) and `hfin` : `conclusion.finWires H`.
- conclusion  $\Phi \vdash \sum_j \lambda_j \ell_j \leq 0 \mapsto$  the goal under `hpost` : `seq.post = .atom .le conclusion (.const 0)`.

Width notes. On the side-condition surface the statement and the display agree: `hwpos` — every free wire of `seq.pre` and of the conclusion typed at a shape of strictly positive total size — appears inline as the display's positive-size row, and it is not optional: without it, zero-size wires make atoms vacuously true and a combination of two vacuous atoms derives a false scalar bound (the zero-size counterexample beside the warrant proof). One direction is genuinely *wider*: the matcher behind `hvalid` normalizes arbitrary two-sided comparison atoms over all five admitted comparators (strict forms contribute their non-strict normal polynomials; equality atoms both polarities) and the replay is degree-blind — the displayed linear zero-form  $\{\leq, =\}$  row is the rule's published register (the note above), not the checked boundary. The displayed cell is the rule's intent; the certified statement is that intent with the register widened exactly as stated.

## Lean verifier receipts

module BernsteinLogic.Soundness; bound build a20d90e66c13... (bound from receipt a9c0e34d3e3c9c8c, 2026-08-03T21:30:36Z). A receipt records that named checking layers accepted a build: (module, compiled-artifact SHA-256, environment SHA-256, checker layers), minted when the checking gate ran; the store receipts attesting the bound build are listed with the layers each run credited. Nothing here asks the reader to trust the store: every layer is an independently runnable program over the quoted sources — rebuild the module and re-run the checkers to reproduce the verdict. Receipts attesting superseded builds credit no layer and are omitted from this rendering (the count of omissions, if any, is noted below).

**HOL verifier receipts**

[documentary](#) hol-strict CLEAN over the ported checker chain: theory `bern_catalogue`, 472 theorems, 0 cheat-tagged, 0 nonstandard axioms (whitelist: `DISK_THM`; the four `bool` axioms) — verification run of 2026-07-22 on an isolated build host, scripts sha-matched verbatim to the sources cited here (git blob `e41b9ed0...`). The ported receipt table replays the  $\lambda = 1$  re-canonicalization accept. Downstream, the same chain carries the checker to a CakeML binary with the `machine_code_sound` tag (theory `bernCertProofARM8`). Divergence repaired, dated: an earlier port run predated the Lean checker's third branch (the mixed tagged-union replay, added 2026-07-19) and carried the two-branch `farkasCheck` with a refusal-direction-only caveat; `farkasCheckFull` — displayed above — is now the honest three-branch disjunction, and the reference checker's Farkas arm consumes it verbatim (verified in the sources at the 2026-07-22 run cited here). Semantic stratum, also ported: the soundness twin `sound_farkas` (theory `bern_tr_ready8`: hol-strict clean, 8 theorems, 0 offences, verification run of 2026-07-22 on an isolated build host, content-addressed at the same sources), stated at `farkasCheckFull` — matching the widened checker arm verbatim — and consumed by the certified-fragment keystone (`checkPf_sound_frag`, theory `bern_tr_splICE`, 20 theorems, 0 offences, same run): a reference-checker accept inside the proven wire fragment yields sequent validity.

HOL receipts are documentary: quoted results of hol-strict runs and census rows from the HOL4 development's build evidence, not minted receipt artefacts. A HOL receipt store (the Lean store's twin) is named future work.

**Proof**

Genre: admissible rule (tier 2) — a proof-tree-rewriting recipe; the general admissible template is stated in the `NORM` section and instantiated here. FARKAS is admissible by reduction to verified machinery: the affine-combination replay is checked computation, and one verified lemma warrants every accepted node.

**Recipe R17.1** (the FARKAS instance). FARKAS has no proof premises — its inputs are sub-conjuncts of  $\Phi$  itself, not sub-derivations:

$$\frac{\{a_j : \ell_j \bowtie_j r_j\}_j \subseteq \Phi \text{ conjunct-wise, } p_j \text{ their } (\cdot) \leq 0\text{-normal forms} \quad \lambda_j \geq 0 \text{ (free-signed on equalities)} \\
 \sum_j \lambda_j p_j \equiv c \text{ (exact canonical fold)} \quad c \text{ shape-stable, finitely typed; wires}(\Phi) \cup \text{wires}(c) \text{ positive-size}}{\Phi \vdash c \leq 0} \quad \text{FARKAS} \rightsquigarrow \text{the checker replays th}$$

The rewrite target contains zero catalogue nodes: the entire content is the checked combination (decoded, sign-gated, atom-sourced, folded — the fragment display quoted above walks the chain) plus the semantic argument of Proposition R17.3. The matcher is wider than the catalogued cell's published register (linear zero-form  $\{\leq, =\}$  rows): it normalizes arbitrary two-sided comparison atoms of the five admitted comparators — strict forms contribute their non-strict normal forms, semantically

(Proposition R17.2) — and the replay is degree-blind (the book note). The catalogued stratum records an unpacking sketch through BERNCONE at degree 1; the shipped warrant is direct, at all tensor shapes, heterogeneous premise-atom shapes included.

**Proposition R17.2** (nonnegative combination, per entry). *Work in an ordered field. Suppose values  $a_j$  satisfy  $a_j \leq 0$ , and weights  $\lambda_j \geq 0$ . Then  $\sum_j \lambda_j a_j \leq 0$ . Moreover the  $(\cdot \leq 0)$ -normal reading of each premise atom delivers such values: an atom  $l \bowtie r$  with  $\bowtie \in \{\leq, <\}$  yields  $l - r \leq 0$ ; with  $\bowtie \in \{\geq, >\}$  it yields  $r - l \leq 0$ ; and an equality yields both  $l - r \leq 0$  and  $r - l \leq 0$  — so a free-sign multiplier  $\nu$  on an equality is realized as the nonnegative weight  $|\nu|$  on the polarity matching  $\nu$ 's sign.*

*Proof.* Each  $\lambda_j a_j \leq \lambda_j \cdot 0 = 0$  (multiplication by a nonnegative element preserves  $\leq$ ), and a finite sum of nonpositive elements is nonpositive, by induction. The polarity readings are the definitions of the normal forms; a holding strict atom *implies* its non-strict normal form — the matcher emits the same polynomial for  $<$  as for  $\leq$ , the weakening being a fact about holding, not a checker step. The equality discipline is the textbook sign convention for multipliers of equality constraints [216, §7.3], realized here syntactically: the matcher sees both polarities, so a negative multiplier is unrepresentable rather than checked for.  $\square$

**Proposition R17.3** (semantic warrant). *Suppose the payload's combination check accepts (any branch), the conclusion term  $c$  is shape-stable and finitely typed, and every wire of  $\Phi$  and  $c$  is typed at a positive-size shape. If  $\sigma \models \Phi$  for an admissible  $\sigma$ , then  $\sigma \models c \leq 0$ .*

*Proof.* The shape and finiteness fields give  $c$  a defined evaluation; fix a conclusion entry  $i$ . The accepted branch fixes a variable space and a per-entry valuation for it: the idx-free branch reads each bare wire *clamped* at entry  $i$  — a rank-0 wire reads its scalar; a positive-rank wire of  $m$  entries reads entry  $i$  when  $i < m$  and entry 0 otherwise, so the read is always an honest in-range entry of the same tensor, and is the plain positional read wherever  $i$  is in range (a read that serves heterogeneous premise atom shapes at every conclusion index); the wire-aware branch reads each projection  $w[j]$  at its fixed coordinate; the mixed branch does both at once, on disjoint variable classes. Two facts from the Setting's broadcast discipline make the clamped reads honest and exact. First, a holding atom never compares unequal positive ranks, and a term's defined broadcast shape forces every positive-rank wire in it to carry that very shape (only rank-0 joins across shapes) — so all positive-rank wires of one premise atom share one shape, and the clamp lands them at one *common* honest entry of that atom, rank-0 wires reading their scalar under any index; here positive size is load-bearing: an atom over positively-sized wires has at least one honest entry for the clamp to land on, so its per-entry normal form is genuinely nonpositive at the branch's valuation (Remark R17.4 shows what happens otherwise). Second, the same discipline pins every positive-rank wire of  $c$  at  $c$ 's own shape, so at conclusion entry  $i$  the clamp is exact and the fold's value at the branch's valuation is entry  $i$ . Thus each sourced entry polynomial is the normal form of a premise conjunct that holds at  $\sigma$ , read per-entry; Proposition R17.2 bounds the weighted fold by 0; the certified fold identity says the fold is  $c$ 's polynomial in the branch's variable space; evaluating at the branch's valuation gives entry  $i$  of  $c$ 's tensor  $\leq 0$ . Entries were arbitrary, so the atom  $c \leq 0$  holds. `sound_farkas` case-splits on the branch disjunct and runs exactly this argument three times.  $\square$

**Remark R17.4** (why positive-size wires are not decoration). Comparison atoms hold per-entry, and a zero-size wire has no entries: at  $w$  of shape  $[0]$ , the atoms  $5 \leq w$  and  $w \leq 3$  both hold *vacuously* — yet their  $(\cdot \leq 0)$ -normal forms  $5 - w$  and  $w - 3$  are perfectly good polynomials, and with  $\lambda = 1$  each they fold to the constant 2. Without the positive-size condition the rule derives  $\vdash 2 \leq 0$  from a satisfiable premise: the classic mismatch between empty-product semantics and nonempty algebra, and the reason the field exists. (A narrower wire discipline once masked the failure by accident of strength; the field is the honest general-shape guard.)

**Remark R17.5** (why the conclusion's shape fields are not decoration). A conclusion mentioning an untyped wire — say  $c' = 0 \cdot w_{999} + c$  with  $w_{999}$  untyped — has a correct canonical polynomial: the dead monomial vanishes in canonical form, so the fold identity holds exactly as it does for  $c$ . But evaluation is structural on the *term*, not on its canonical form — it still reads  $w_{999}$ , which is untyped — so the conclusion never evaluates, and the concluded atom never holds at any valuation. The shape-stability and finiteness fields make “the fold is  $c$ 's polynomial” imply “ $c$  evaluates”, closing the gap between syntax and semantics.

**Remark R17.6** (the three branches are one algorithm). The branches differ only in the variable space where polynomials are compared: canonical wire-keyed forms; projection coordinates keyed by an injective (wire, coordinate) pairing — distinct wires *must* get distinct variables, since a composite may mix projections of several wires and conflating  $w_0[j]$  with  $w_2[j]$  would let semantically different polynomials collide (a one-line witness: from the holding premise  $w_0[0] \leq 0$  at  $w_0[0] = -1$ ,  $w_2[0] = 1$ , the conflated space accepts the false conclusion  $w_2[0] \leq 0$ ); and the mixed tagged union, where bare wires and projections are disjoint classes — in particular a bare  $w$  is never identified with  $w[0]$ : the identification variant admits a false sequent (witness:  $w = (-1, 1)$  satisfies  $w[0] \leq 0$ , and the identified space would conclude the whole-wire bound  $w \leq 0$ , false at the second entry), so the tagging is a soundness fact, not a convenience. Entry encoding, sign gates, atom sourcing, and the exact fold are the same gates, replayed branch by branch in its own variable space (the branch definitions cited at the anchors), and each branch carries its own per-entry valuation in the soundness proof.

**Remark R17.7** (relation to the literature). The linear ancestor is Farkas' lemma [73]; the multiplier sign conventions ( $\lambda \geq 0$  on inequalities, free on equalities) are [216, §7]. As everywhere in this calculus, only the sound (trivial) direction is claimed: the classical lemma's content — that every valid affine consequence *has* such a combination — is a completeness statement about producers, never consulted by the kernel. Degree-blindness of the replay places the rule's polynomial generalizations in the Krivine–Handelman family [110, 144], reached in this catalogue through SYZGYV and BERNCONE rather than by widening this rule.

## Rule 18. SUBDIVIDE (admissible rule)

### The rule (Steele metanotation)

as realized in the mechanized development; source row: `rules.toml` — *Subdivide*. The metanotation statement is typeset by hand for notational quality; its mechanized ground truth is the Lean statement below, extracted from the sources at every build of this book and hash-bound. The rule *roster* is machine-checked (every mechanized rule tag round-trips to exactly one catalogue row); the statement *text* is editorial, checked by eye against the extracted Lean beside it.

$$\frac{\Phi \vdash x \in \mathcal{R}(\Delta, S) \quad \{(\Delta_k, S_k)\}_{k=1}^N \text{ finite, with cover side-condition } \mathcal{R}(\Delta, S) \subseteq \bigcup_k \mathcal{R}(\Delta_k, S_k) \quad \forall k. \Phi \wedge (x \in \mathcal{R}(\Delta_k, S_k)) \vdash \Psi}{\Phi \vdash \Psi} \text{ SUBDIVIDE}$$

SUBDIVIDE is the case-split rule of region reasoning: from a proven membership  $\Phi \vdash x \in \mathcal{R}(\Delta, S)$ , a finite family of branch regions covering the parent, and one sub-proof of the goal per branch (each under the strengthened premise  $\Phi \wedge x \in \mathcal{R}(\Delta_k, S_k)$ ), it concludes  $\Phi \vdash \Psi$  on the whole parent region. It is degree escalation's partner and load-bearing for every non-toy proof: where a single BERNCONE certificate at feasible degree is too coarse, a producer splits the region, certifies each piece at low degree, and lets SUBDIVIDE reassemble the global conclusion — the branch-and-bound shape that makes Bernstein enclosures converge.

What the checker recomputes, given the payload (parent region, branch family, per-branch sub-proofs): that the parent region reads as a closed interval — ambient dimension 1, support exactly two vertices at distinct coordinates, empty extension set; that every branch region reads as a closed interval and is tied to its own extension set; and that the branch intervals *chain* across the parent interval — a greedy reach, iterated to its fixpoint, that extends past any interval whose left endpoint has already been reached and must arrive at the parent's right endpoint. Everything beyond this fragment (extension-ray parents or branches, regions of dimension  $\geq 2$ , supports of more than two vertices) is refused, never accepted on faith. The repair for that narrowness is CONVINTRO:  $n$ -dimensional box grids arise by *nesting* per-coordinate splits across several rule applications, not inside one — each branch establishes its coordinate facts as order atoms, and CONVINTRO converts them back into the region atom the next coordinate's split consumes, so the one-dimensional rule reaches every box grid without widening its checker.

Each hypothesis is load-bearing. Drop the cover check and a producer omits the branch where the goal fails — a gap family such as  $[1, \frac{4}{3}] \cup [\frac{3}{2}, 2]$  over  $[1, 2]$  proves the goal everywhere except where it is false. Drop the branch-region tie and the chained intervals belong to different regions than the ones the sub-proofs assume. Drop the branch-premise shape and a sub-proof could be consulted outside the piece it was proven on. Drop the branch-conclusion tie and the branches may prove any formulas whatever —  $\Psi$  never enters their obligations while the rule concludes it anyway. Drop the parent region premise and a valuation satisfying  $\Phi$  with the point outside the parent falls through every branch: the cover says nothing about it, yet the rule still concludes  $\Psi$  there. The certificate slot for cover evidence rides the wire but is deliberately *not consulted*: the checker recomputes the cover from the branch regions themselves, so ignoring the slot can only make checking stricter, never unsound.

**notes** The region variable itself plays no role in the cover geometry: the soundness argument feeds the *same* evaluated point to the parent and to the selected branch, so no tie between the term and the cover is needed — the cover is a fact about intervals, not about wires. A future interpretation may read per-gap infeasibility certificates out of the wire slot; the catalogued stratum records the corresponding unpacking sketch (per-branch cuts discharged through FARKAS and  $\vee$ -elimination).

```

**What the cover check means — and what it does not.** The side condition appears in the payload as the single name `coverInfeasibilityValid`, so this book binds its meaning by displaying the definition chain in full, from the checker sources. Reading the chain: `ExtensionSet.intervalD?` is the closed-interval reading of a region — it succeeds only on the checkable fragment (dimension 1, two-vertex support at distinct coordinates, empty extension set), returning sorted endpoints, and everything else reads none, which the cover check turns into refusal. `coverExtendPass` is one greedy pass: extend the reach past any interval whose left endpoint has been reached; `coverReach` iterates it, and as many passes as there are intervals suffice for the fixpoint (a

productive pass strictly increases the reach onto a new right endpoint, of which there are only finitely many). `coverChainCheck` asks whether the reach from the parent's left endpoint arrives at its right endpoint; `coverCheck` assembles the whole condition, tying each branch's extension set to its simplex on the way.

What a skeptical reader should confirm by eye: the region term and the wire-borne cover certificate are *ignored* — the relation discards both arguments, and the cover is recomputed from the branch regions alone (the recompute pattern; a forged certificate cannot influence the verdict, and a missing one costs nothing); no valuation is consulted anywhere; and the branch sub-proofs enter soundness, not the cover computation — the checker decides pure interval geometry.

BernsteinLogic.Core.Catalogue . **ExtensionSet.intervalID?**

definition bound

```

/-- The closed-interval reading of a region `R(Δ, S)`: succeeds iff the
ambient dimension is 1, the simplex's support is exactly two vertices at
distinct coordinates, and the extension set is empty – returning the
region's endpoints, sorted (`lo < hi` by construction). Everything else
reads `none` (and the cover check then rejects). -/

## Correspondence (Steele display ↔ Lean)

reviewer-certified against the displayed texts

The dictionary below is a reviewer-certified statement of how the mechanized statements above interpret the displayed rule: display metavariable  $\mapsto$  Lean binder, each display hypothesis  $\mapsto$  the premise or side condition carrying it, the display conclusion  $\mapsto$  the goal — with any deliberate difference in width between display and mechanization named outright. Certification is recorded as a hash triple over (the displayed cell, the extracted statement texts, this dictionary's own text); if any of the three changes, this block turns amber until a reviewer re-certifies. The correspondence claim itself remains editorial — reviewer-grade, not machine-checked; its machine-checked successor types each soundness statement against the rule as a structured object, and supersedes this block per rule as it lands.

Judgment frame as in **Ax**; sub-derivation premises as at **WEAKEN**.

- $x \mapsto \text{termX} : \text{Term}$  (a free term — unlike **BERNCONE**, no wire tie is needed here: the note above explains why);  $(\Delta, S) \mapsto \text{simplex}, S$ ; the branch family  $\{(\Delta_k, S_k)\}_{k=1}^N \mapsto \text{branchSimplex}, \text{branchS} : \text{Fin } n\text{Branches} \rightarrow \_$ .
- region premise  $\Phi \vdash x \in \mathcal{R}(\Delta, S) \mapsto \text{ihRegion}$  with  $\text{hregionPost} : \text{regionPremise.post} = \text{.inRegion termX simplex S}; \Phi$  shared via  $\text{hpre}$ .
- the branch judgments  $\forall k. \Phi \wedge (x \in \mathcal{R}(\Delta_k, S_k)) \vdash \Psi \mapsto \text{ihBranch}$  with  $\text{hbranchPre}$  pinning each branch premise to the displayed conjunction in the displayed order ( $\Phi$  left) and  $\text{hbranchPost}$  tying every branch conclusion to  $\text{seq.post}$  —  $\Psi$  is whatever formula the conclusion sequent carries; nothing constrains its shape.
- the cover side-condition  $\mathcal{R}(\Delta, S) \subseteq \bigcup_k \mathcal{R}(\Delta_k, S_k) \mapsto \text{hcover} : \text{coverInfeasibilityValid}$ , i.e.  $\text{coverCheck} = \text{true}$ : the parent extension set must present as a 1-dimensional interval ( $\text{ExtensionSet.interval1D?}$  — outside that fragment the check refuses, so the certified reach of the displayed set-inclusion is the interval fragment, the **CONVELIM** class), each branch's simplex-tie is checked, and the greedy chain ( $\text{coverExtendPass}/\text{coverReach}/\text{coverChainCheck}$ , certified alongside) verifies the branch intervals chain across the parent interval — a decidable *sufficient* witness of the displayed inclusion, conservative like every refusal boundary.
- consumed by nothing: the payload's cover certificate term rides into  $\text{coverInfeasibilityValid}$  as an ignored argument (the binder is underscore-named in the displayed definition) — retained for the per-gap-infeasibility interpretation the note records; the realized checker recomputes the cover itself and reads no producer-supplied cover data.

Width note: within the interval fragment neither side is wider — every other hypothesis is consumed, and the displayed rule's “finite family” is carried by the  $\text{Fin } n\text{Branches}$  index type itself.

## Lean verifier receipts

module BernsteinLogic.Soundness; bound build a20d90e66c13... (bound from receipt a9c0e34d3e3c9c8c, 2026-08-03T21:30:36Z). A receipt records that named checking layers accepted a build: (module, compiled-artifact SHA-256, environment SHA-256, checker layers), minted when the checking gate ran; the store receipts attesting the bound build are listed with the layers each run credited. Nothing here asks the reader to trust the store: every layer is an independently runnable program over the quoted sources — rebuild the module and re-run the checkers to reproduce the verdict. Receipts attesting superseded builds credit no layer and are omitted from this rendering (the count of omissions, if any, is noted below).

## HOL verifier receipts

**documentary** hol-strict CLEAN over the ported checker chain: theory bern\_catalogue, 472 theorems, 0 cheat-tagged, 0 nonstandard axioms (whitelist: DISK\_THM; the four bool axioms) — verification run of 2026-07-22 on an isolated build host, scripts sha-matched verbatim to the sources cited here (git blob e41b9ed0...). The ported receipt table replays the cover battery: the positive chain  $([1, \frac{3}{2}] \cup [\frac{3}{2}, 2]$  over  $[1, 2]$ ) and four negative controls — the gap mutant, a point-supported branch, an extension-ray parent, and untied branch simplices. Representation seam, inventoried in the script: the indexed branch family becomes one list of (simplex, extension-set) pairs in index order, and the Lean relation's two inert arguments (region term, cover certificate) are not reproduced — both value-preserving deltas under the port's seam discipline.

HOL receipts are documentary: quoted results of hol-strict runs and census rows from the HOL4 development's build evidence, not minted receipt artefacts. A HOL receipt store (the Lean store's twin) is named future work.

## Proof

Genre: admissible rule (tier 2) — a proof-tree-rewriting recipe; the general admissible template is stated in the NORM section and instantiated here. SUBDIVIDE is the genuinely one-node-to-many member of this batch: its rewrite is a case analysis over the branch sub-proofs, and the checked cover condition is what makes the case analysis exhaustive.

**Recipe R18.1** (the SUBDIVIDE instance). The node carries a region premise and one sub-proof per branch:

$$\frac{\mathcal{T}_0 \triangleright (\Phi \vdash x \in \mathcal{R}(\Delta, S)) \quad \mathcal{T}_k \triangleright (\Phi \wedge (x \in \mathcal{R}(\Delta_k, S_k)) \vdash \Psi) \quad (k = 1, \dots, N) \quad \mathcal{R}(\Delta, S) \subseteq \bigcup_k \mathcal{R}(\Delta_k, S_k) \text{ (checked: the interval chain)}}{\Phi \vdash \Psi} \text{SUBDIVIDE} \rightsquigarrow \text{select the covering branch; consult its subtree.}$$

Conceptually the rewrite is an  $N$ -way case analysis: at any valuation satisfying  $\Phi$ , the premise puts the evaluated point in the parent region, the cover places it in some branch region  $k$ , and  $\mathcal{T}_k$ 's strengthened premise then holds — so  $\mathcal{T}_k$  delivers  $\Psi$ . The shipped warrant packages this selection argument as one verified lemma rather than as catalogue surgery (the catalogued stratum records the corresponding derivation sketch through FARKAS-discharged infeasibility cuts and  $\vee$ -elimination); the checked side condition is Proposition R18.2, the exhaustiveness of the case analysis.

**Proposition R18.2** (the greedy chain covers). *Let ivs be a finite list of closed intervals and  $\text{lo} < \text{hi}$  rationals. Define one greedy pass  $r \mapsto \text{extend}(r)$ : fold over the list, replacing  $r$  by an interval's right endpoint whenever that interval's left endpoint is  $\leq r$  and its right endpoint is  $> r$ . If after  $|\text{ivs}|$  passes from  $\text{lo}$  the reach is  $\geq \text{hi}$ , then  $[\text{lo}, \text{hi}] \subseteq \bigcup \text{ivs}$ .*

*Proof.* Maintain the invariant: the reach  $r$  satisfies  $\text{lo} \leq r$ , and either  $r \leq \text{lo}$  or every point of  $[\text{lo}, r]$  lies in some interval of the full list. It holds initially ( $r = \text{lo}$ , the first disjunct). One pass preserves it: when the fold takes an interval  $[a, b]$  with  $a \leq r < b$ , any point  $y \in [\text{lo}, b]$  is either  $\leq r$  — covered by the invariant, or by  $[a, b]$  itself in the  $r \leq \text{lo}$  base case since then  $a \leq \text{lo} \leq y$  — or lies in  $(r, b] \subseteq [a, b]$ ; and when the fold declines an interval the state is unchanged. As many passes as there are intervals reach the fixpoint: a productive pass strictly increases  $r$  onto a new interval's right endpoint, of which there are at most  $|\text{ivs}|$ , and an unproductive pass is already the fixpoint. If the final reach is  $\geq \text{hi} > \text{lo}$ , the invariant's second disjunct is in force and covers all of  $[\text{lo}, \text{hi}]$ .  $\square$

**Proposition R18.3** (semantic warrant). *Suppose the region premise and every branch premise-sequent are semantically valid, the branch premises have the checked shape ((branch  $k$ )'s premise is  $\Phi \wedge (x \in \mathcal{R}(\Delta_k, S_k))$  and its conclusion is  $\Psi$ ), and the cover check accepts. Then  $\Phi \vdash \Psi$  is semantically valid.*

*Proof.* Fix an admissible  $\sigma \models \Phi$ . The region premise puts the evaluated point  $q$  of  $x$  in  $\mathcal{R}(\Delta, S)$ ; the accepted cover check says the parent reads as a closed interval  $[\text{lo}, \text{hi}]$  (dimension 1, two-vertex support,  $S = \emptyset$ ), so  $q$ 's coordinate lies in  $[\text{lo}, \text{hi}]$  — eliminating the parent's barycentric weights to endpoint bounds. By Proposition R18.2 some branch interval contains the coordinate. Each branch interval was itself produced by running the closed-interval reading on that branch's own simplex and extension set (the cover check refuses any branch it cannot so read, and checks the tie between the two), so “the coordinate lies in branch  $k$ 's interval” converts back — re-introducing barycentric weights over branch  $k$ 's own support from the two endpoint bounds — into membership of

the *same* evaluated point in  $\mathcal{R}(\Delta_k, S_k)$ : this is where nothing about the region term is needed beyond its one evaluation, used twice. Hence  $\sigma$  satisfies branch  $k$ 's premise  $\Phi \wedge (x \in \mathcal{R}(\Delta_k, S_k))$ ; its validity delivers its conclusion, which is  $\Psi$  by the checked branch–conclusion shape.  $\square$

*Remark R18.4* (what breaks without the cover check). Everything: the rule without the cover is “prove  $\Psi$  wherever convenient.” The canonical mutant is the gap family  $\{[1, \frac{4}{3}], [\frac{3}{2}, 2]\}$  over the parent  $[1, 2]$  — each branch sub-proof can be perfectly honest, and the goal simply fails on  $(\frac{4}{3}, \frac{3}{2})$ , where no branch constrains it. The greedy reach from 1 arrives at  $\frac{4}{3}$  and stops: no remaining interval's left endpoint is  $\leq \frac{4}{3}$ , so the check refuses. The checker's replayed battery keeps this mutant, together with a point-supported branch (a degenerate interval that cannot read), an extension-ray parent, and untied branch simplices, as standing negative controls.

*Remark R18.5* (the fragment boundary, and why refusal is the right default). The checkable fragment is deliberate: 1-dimensional closed intervals, chained. Extension-ray parents or branches, higher-dimensional regions, and richer supports are refused — not because the rule is false there, but because no verified covering argument exists there yet, and the fail-toward-refusal posture makes the unproven territory unrepresentable. Box domains lose no expressive reach:  $n$ -dimensional grids are expressible by nesting per-coordinate splits across several applications, each within the fragment, the inner split's parent membership entering through the outer split's branch premise. The cover-certificate wire slot is likewise part of the posture: recomputing the cover from the branch regions means a forged certificate cannot influence the verdict — ignoring the slot cannot affect it either — and a future interpretation that additionally *required* per-gap infeasibility certificates from the slot would only tighten the check (one that instead accepted new covers on certificate evidence would be a new checking route, owing its own soundness argument).

*Remark R18.6* (relation to the literature). The rule is the reassembly half of branch-and-bound over Bernstein enclosures: subdivision sharpens coefficient bounds quadratically in the subdivision width and drives them to the range in the limit [85], with the subdivision algorithms themselves classical [40, 151]. In that literature the splitting is a completeness device — *some* refinement certifies any strict global fact; here only the soundness direction enters the kernel: whatever refinement the producer chose, the chain check makes its case analysis exhaustive. None of the producer-side effectivity data (piece counts, degrees, tolerances) is consulted.

## Rule 19. LiRPA (admissible rule)

### The rule (Steele metanotation)

as realized in the mechanized development; source row: `rules.toml` — *LiRPA*. The metanotation statement is typeset by hand for notational quality; its mechanized ground truth is the Lean statement below, extracted from the sources at every build of this book and hash-bound. The rule *roster* is machine-checked (every mechanized rule tag round-trips to exactly one catalogue row); the statement *text* is editorial, checked by eye against the extracted Lean beside it.

$$\frac{\begin{array}{ccccc} \Phi \vdash a \leq h & \Phi \vdash h \leq b & \text{relu}_{\{h\} \rightarrow \{y\}} \in H & a < 0 & 0 < b \\ \alpha a + \beta \leq 0 & \beta \leq 0 & \alpha b + \beta \leq b & & \\ 0 \leq \gamma a + \delta & 0 \leq \delta & b \leq \gamma b + \delta & & \end{array}}{\Phi \vdash (\alpha h + \beta) \leq y \wedge y \leq (\gamma h + \delta)} \quad \text{LiRPA}$$

LiRPA is the calculus's neural-network bound-propagation rule — the certificate form of the linear relaxation of the ReLU activation that bound-propagation verifiers compute (the CROWN/LiRPA family, the triangle relaxation, DeepPoly). Given already-proven box bounds  $\Phi \vdash a \leq h$  and  $\Phi \vdash h \leq b$  on the preactivation wire of a cited ReLU application, with  $a < 0 < b$  (the box straddles the kink — the *unstable* case, in the verification literature's vocabulary), it concludes the two-sided affine envelope  $\alpha h + \beta \leq y \wedge y \leq \gamma h + \delta$  on the application's output wire  $y$ . The producer finds the envelope however it likes — CROWN's adaptive slopes, the triangle relaxation's chord, any heuristic — and ships only the box endpoints and the four coefficients; no relaxation machinery is re-run or trusted.

What the checker recomputes, given the payload (two premise proofs, the two wires, six rationals): the *linkage* — the hypernet really contains a packaged ReLU application at exactly these ports, of positive total size (a one-line decidable port lookup); that the premises are literally the atoms  $a \leq h$  and  $h \leq b$  over one shared premise formula; the sign conditions  $a < 0$  and  $0 < b$ ; the six envelope inequalities, exactly over  $\mathbb{Q}$  — the lower line under the function at the three checkpoints  $a, 0, b$  ( $\alpha a + \beta \leq 0, \beta \leq 0, \alpha b + \beta \leq b$ ) and the upper line above it at the same three ( $0 \leq \gamma a + \delta, 0 \leq \delta, b \leq \gamma b + \delta$ ); and that the conclusion is *exactly* the pinned conjunction of the two affine comparison atoms, built by the checker from the coefficients — the producer proposes no conclusion shape at all.

Each hypothesis but one is load-bearing. Drop the linkage and  $y$  is an arbitrary wire with no semantic tie to  $h$  (the rule as first staged had exactly this gap and was kept vacuous — rejecting every certificate — until the port-lookup premise landed). Drop the lower kink check ( $\beta \leq 0$ ) and the chord through the box endpoints, which passes both endpoint checks, would certify as a lower envelope while lying strictly above the function at  $h = 0$ . (The upper kink check  $0 \leq \delta$  is the one redundancy: under the strict straddle the two upper endpoint checks already force  $\delta \geq -ab/(b-a) > 0$  — evaluate the affine interpolation of the endpoint bounds at 0 — so it rides along because the certificate's check set is the uniform six.) Drop an endpoint check and a steep line passing the remaining two checkpoints escapes the function at the dropped end (the proof section constructs both failures). The box premises themselves are what make an affine *upper* envelope possible at all — no affine function dominates  $\max(0, h)$  on all of  $\mathbb{Q}$  — and what license lower-line slopes outside  $[0, 1]$ .

**notes** The family's shared machinery — the packaged-node linkage, the elementwise two-case semantic contract, and the conservativity warrant behind it — is stated once, in this section's recipe preamble, and referenced by the four sibling rules (ReLU-POS, ReLU-NEG, ReLU-NN, ReLU-ABOVE). One envelope serves the whole node: the rule is elementwise over the cited application's tensor shape, with a single  $(a, b, \alpha, \beta, \gamma, \delta)$  for every entry — per-entry envelopes are expressed with singleton-shaped applications. The payload additionally declares a denominator bound on its witness rationals (a size claim for resource accounting; it carries no proof-theoretic weight in the soundness argument). The rule's name is the literature's: linear-relaxation-based perturbation analysis [243].

### Lean statement

**The linkage and the pinned conclusion, from the checker sources.** `reluLinked` is the whole of the family's side condition: the hypernet's application list contains a packaged ReLU application at exactly the cited preactivation/output ports, of positive total size — one decidable lookup (`PrimApp.isReluAt`), no pattern-matching over composites. The positive-size gate refuses vacuous surface at the source: a size-zero node's comparison atoms hold vacuously, and a fact no valuation can falsify must not be citable (the same lesson the FARKAS rule's zero-size counterexample taught that payload). `affineWireTerm` and `liRpaConclusionForm` pin the conclusion: the rule concludes exactly the conjunction of the two affine comparison atoms, built from the payload coefficients — there is no producer-supplied conclusion shape to audit.

BernsteinLogic.Core.Catalogue . **PrimApp.isReluAt**

definition bound

```
-- Port-lookup matcher for the ReLU linkage: a packaged ReLU
-- application at exactly these ports, of positive total size. The size
-- gate is the shape-aware rider (conservative-extension memo register 2,
-- the `PFarkasData.wiresPos` lesson generalized): a shape-[0] node's
-- atoms hold vacuously, and vacuous surface must not be citable — the
```

```

rules refuse it at the linkage, before any soundness question arises. -/
def PrimApp.isReluAt (preact post : Wire) : PrimApp → Bool

    (.atom .le (.var post) (affineWireTerm δ γ preact))

```

**The verified chain.** `reluLinked_facts` turns the linkage into semantics: under any admissible valuation the two cited wires carry tensors of one shared shape and positive entry count, related entrywise by the two-case ReLU relation. The four interpolation lemmas are the checkpoint arithmetic — an affine function suitably bounded at an interval's endpoints is bounded on the interval, one lemma per envelope side per sign branch — and `sound_lirpa` assembles them entrywise into the rule's warrant.

BernsteinLogic.Soundness . **reluLinked\_facts**

statement bound

```

/-- Extraction for the realized B12 linkage: under any admissible
valuation, a cited ReLU application yields both wire tensors – one
shared shape, positive entry count – and the elementwise two-case
relation. Typing rides `H.typeConsistent` at the cited application (no
payload typing fields needed – the wire format is untouched). -/

```

**Why consuming the packaged two-case fact is not new kernel content.** The two-case relation is the packaged symbol's defined semantics, consumed by the family as model fact at every positive size; what this pair of declarations adds is the conservativity warrant — that the definition mints no genuinely new primitive: `reluExpH` is the definitional expansion (a copy, a sign-split cell complex, an indicator cast, and an exact rank-0 contraction), and `relu_projection` shows — both directions — that the two-case relation is exactly the expansion's model-level facts existentially projected onto the external ports, proven at the canonical single-entry instance. The boundary point  $h = 0$  rides the one-hot cell semantics: both cells admit it, and every admissible choice forces  $y = 0$ . Applications of total size other than one currently have no core expansion (a recorded packing gap in the development's notes): at those sizes the node stands as a genuine primitive with the stated semantics — the rules remain sound there, while the not-a-new-primitive claim is certified only at size one.

BernsteinLogic.ReluExpansion . **relu\_projection**

statement bound

```
/-- **Obligation P (the projection lemma), both directions**: the
packaged ReLU's derived sp-fact – the two-case relation – EQUALS the
expansion's sp-facts existentially projected onto the external ports.
The internal wires (the copies, the indicators, the cast image, the
rank-0 legs) are exactly the existentially-quantified content of the
valuation; the boundary case  $p = 0$  is covered because both one-hot
choices are admissible there and both force  $y = 0$ . -/
theorem relu_projection (p y : ℚ) :
  (∃ σ : reluExpH.Valuation, σ.Admissible ∧

## Correspondence (Steele display $\leftrightarrow$ Lean)

**reviewer-certified against the displayed texts** The dictionary below is a reviewer-certified statement of how the mechanized statements above interpret the displayed rule: display metavariable  $\mapsto$  Lean binder, each display hypothesis  $\mapsto$  the premise or side condition carrying it, the display conclusion  $\mapsto$  the goal — with any deliberate difference in width between display and mechanization named outright. Certification is recorded as a hash triple over (the displayed cell, the extracted statement texts, this dictionary's own text); if any of the three changes, this block turns amber until a reviewer re-certifies. The correspondence claim itself remains editorial — reviewer-grade, not machine-checked; its machine-checked successor types each soundness statement against the rule as a structured object, and supersedes this block per rule as it lands.

Judgment frame as in Ax; sub-derivation premises as at WEAKEN. This dictionary doubles as the family preamble: its linkage row is shared verbatim by the four sibling rules.

- $h \mapsto \text{preact} : \text{Wire}; y \mapsto \text{post} : \text{Wire}; a, b, \alpha, \beta, \gamma, \delta \mapsto$  the six rational binders of the same names in `sound_lirpa`.
- the linkage premise  $\text{relu}_{\{h\} \rightarrow \{y\}} \in H \mapsto \text{hlink} : \text{reluLinked } H \text{ preact post}$  — membership *plus* the positive-size gate: unfolding (the definition above), the certified premise demands a packaged ReLU application at exactly these ports *of positive total size*. The display's bare  $\in$  shows no size condition; the certified linkage is strictly narrower, by design (vacuous surface refused at the source — the intro above), and the narrowing is family-wide.
- box premises  $\Phi \vdash a \leq h$  and  $\Phi \vdash h \leq b \mapsto \text{ihl}, \text{ihu}$  with posts pinned by `hlowerPost : lowerPremise.post = .atom .le (.const a) (.var preact)` and `hupperPost : upperPremise.post = .atom .le (.var preact) (.const b)` — displayed comparators and operand orders carried exactly;  $\Phi$  shared three ways via `hpre` and `hpreMatch`.
- the eight arithmetic side conditions  $\mapsto \text{hAneg}, \text{hBpos}, \text{hLower1} \text{--} \text{hLower3}, \text{hUpper1} \text{--} \text{hUpper3}$ , verbatim over  $\mathbb{Q}$  — scalar hypotheses on the payload rationals, not judgments.
- conclusion  $\Phi \vdash (\alpha h + \beta) \leq y \wedge y \leq (\gamma h + \delta) \mapsto$  the goal under `hpostForm : lirpaConclusionForm preact post` applied to the four coefficients and `seq.post` to the conjunction of the two affine atoms in the displayed order (lower envelope left). Spelling drift, disclosed: the pinned affine term is `affineWireTerm`'s offset-first  $\beta + \alpha h$ , where the display writes  $\alpha h + \beta$  — semantically identical, but formulas are ordered trees, so the certified rule accepts exactly the offset-first spelling (the `CONVELIM/CONVINTRO` build-output class).

Width notes beyond the linkage gate: the certified atoms are elementwise over the cited application's tensor shape — one envelope for every entry, per the note above — where the display reads scalar; that is the batch semantics of the atom grammar, not a strengthening. `reluLinked_facts`, the four interpolation lemmas, `relu_projection`, and `reluExpH` are certified alongside as machinery: the first extracts the elementwise two-case relation the family consumes, the last two ground the packaged symbol in the core expansion — they are *about* the linkage, in the satellite sense of ORE's `ctx`-rule. No hypothesis of `sound_lirpa` is unused, and nothing certified is wider than the display.

## Lean verifier receipts

module `BernsteinLogic.Core.Catalogue`; bound build `cbc92e976a1d...` (bound from receipt `5abdb3589707b5df`, 2026-08-03T21:30:33Z). A receipt records that named checking layers accepted a build: (module, compiled-artifact SHA-256, environment SHA-256, checker layers), minted when the checking gate ran; the store receipts attesting the bound build are listed with the layers each run credited. ## HOL verifier receipts

documentary hol-strict CLEAN: theory bern\_tr\_catdata2, 272 theorems, 0 cheat-tagged, 0 nonstandard axioms (whitelist: DISK\_THM; the four bool axioms) — verification run of 2026-07-22 on an isolated build host, against a content-addressed checkout of

the exact sources cited here (git blob cd3c1e95...). The proof-object stratum is ported as one mutual datatype family with a mutual wellformedness predicate, exactly as the Lean mutual inductive block; this rule's arm carries the two premise sub-proofs, the six sandwich inequalities verbatim, the application-list linkage (`reluLinkedB`, theory `bern_tr_catdata`, 252 theorems, 0 offences, same run — the lookup the earlier port excluded wholesale now has a ported realization), and the conclusion form (`lirpaConclusionFormB`, theory `bern_tr_catforms`, 23 theorems, 0 offences). The receipt theorem cited here is the kernel-evaluated accept/reject pair over a hypernet carrying the packaged ReLU application. The four bound lemmas behind the sandwich soundness are ported as well (`lirpa_lower_neg` / `lirpa_lower_pos` / `lirpa_upper_neg` / `lirpa_upper_pos`, theory `bern_tr_soundmid`, 16 theorems, 0 offences, run of 2026-07-22). Honest residue: the apex semantic theorem assembling them (the Lean development's `sound_lirpa`) is not yet ported; its ingredients above are.

HOL receipts are documentary: quoted results of `hol-strict` runs and census rows from the HOL4 development's build evidence, not minted receipt artefacts. A HOL receipt store (the Lean store's twin) is named future work.

## Proof

Genre: admissible rule (tier 2) — a proof-tree-rewriting recipe. This section additionally carries the *family template* for the five ReLU rules (`LIRPA`, `RELU-POS`, `RELU-NEG`, `RELU-NN`, `RELU-ABOVE`): the packaged-node machinery they share is stated once here, and the four sibling sections instantiate it by reference.

**Recipe R19.1** (the ReLU family template). The general admissible template — one rule node rewrites to a derivation fragment over core and previously-justified rules with the same conclusion — is stated in full in the `PCONSTEXACT` section; the five ReLU rules are its instances over one shared semantic fact. The realized term grammar has no `relu` symbol: `relu` is a *packaged hypernet primitive*, an application  $\text{relu}_{\{h\} \rightarrow \{y\}} \in H$  with preactivation (input) wire  $h$  and output wire  $y$ . Every family rule cites it through one side condition, the *linkage*  $\text{reluLinked}(H, h, y)$ : the hypernet's application list contains a packaged ReLU at exactly these ports, of positive total size — a single decidable port lookup, not a pattern-match over composites. The packaged node's semantic contract is the elementwise two-case fact: under every admissible valuation, at every entry  $i$  of the node's (shared) tensor shape,

$$(h_i \leq 0 \wedge y_i = 0) \vee (0 \leq h_i \wedge y_i = h_i).$$

Three remarks fix what the template means and what it does not.

(i) *The rewrite shape.* Each family node rewrites to a case analysis over this disjunction: the sign-split fact enters the branch contexts (context-carrying  $\vee E$  — the disjunction arrives as a sub-conjunct of the premise; see the  $\vee E$  section's note), equality transport (`EqELIM`) carries the branch equality  $y = 0$  or  $y = h$  through the goal, and `ARITHATOM/NORM` plumbing normalizes atom orientations. Where a branch discharges fully into catalogue nodes the instance recipe displays the derivation (`RELU-NN` and `RELU-ABOVE`); where it does not — the boundary branches of `RELU-POS/RELU-NEG` need an antisymmetry step no catalogue rule provides — the instance says so and the rule is admissible by *reduction to verified machinery*, the honest tier note the `PCONSTEXACT` section established.

(ii) *The semantic contract and the conservativity warrant, kept distinct.* The two-case relation is the packaged symbol's *defined* semantics — part of what an admissible valuation of a hypernet containing the node means, at every entry of every positive-size application — and the family's soundness lemmas consume it as model fact at any size (that is (iii)'s extraction lemma). What the conservativity warrant adds is that the definition mints no genuinely new primitive: a definitional expansion into core primitives (a copy, the sign-split cell complex  $\Sigma^\pm$ , an indicator cast, and an exact rank-0 contraction — `reluExpH`), a typing rule derivable from the expansion's, and the projection theorem `relu_projection`: *both directions*, the two-case relation is exactly the expansion's model-level facts existentially projected onto the external ports — proven at the canonical single-entry instance. The boundary point  $h = 0$  rides the one-hot cell semantics: both cells of  $\Sigma^\pm$  admit it, and every admissible choice forces  $y = 0$ . Scope, stated loudly: applications of total size other than one currently have *no* core expansion (a recorded packing gap), so at those sizes the packaged node stands as a genuine primitive with the stated semantics — the five rules remain sound there, consuming the defined relation, while the not-a-new-primitive claim is certified only at size one.

(iii) *The shipped verified objects.* Per the catalogue's convention, each family rule ships a direct soundness lemma factoring through already-verified machinery rather than a derivation object: `reluLinked_facts` converts the linkage, under any admissible valuation, into (a) tensors at both ports, (b) one shared shape of positive entry count, and (c) the per-entry two-case relation; each rule's lemma is then an entrywise case analysis. The positive-size gate inside the linkage is deliberate hygiene: a size-zero node's comparison atoms hold vacuously, and vacuous surface must not be citable — the general lesson of the `FARKAS` rule's zero-size counterexample, enforced here at the source.

**Recipe R19.2** (the `LIRPA` instance — subdivide at the kink). The node, with its premise subtrees and side conditions:

$$\frac{\begin{array}{ccccccc} \mathcal{T}_a \triangleright \Phi \vdash a \leq h & \mathcal{T}_b \triangleright \Phi \vdash h \leq b & \text{relu}_{\{h\} \rightarrow \{y\}} \in H & a < 0 & 0 < b \\ \alpha a + \beta \leq 0 & \beta \leq 0 & \alpha b + \beta \leq b & 0 \leq \gamma a + \delta & 0 \leq \delta & b \leq \gamma b + \delta \\ \hline \Phi \vdash (\alpha h + \beta) \leq y \wedge y \leq (\gamma h + \delta) \end{array}}{\text{LIRPA}}$$

rewrites to a two-branch case analysis at the kink,

$$\frac{\mathcal{D}_- \triangleright \Phi \wedge (h \leq 0) \vdash (\alpha h + \beta) \leq y \wedge y \leq (\gamma h + \delta) \quad \mathcal{D}_+ \triangleright \Phi \wedge (0 \leq h) \vdash (\alpha h + \beta) \leq y \wedge y \leq (\gamma h + \delta)}{\Phi \vdash (\alpha h + \beta) \leq y \wedge y \leq (\gamma h + \delta)} \text{CASES}$$

where the case split is the box subdivision  $[a, b] = [a, 0] \cup [0, b]$  (region atoms enter from the order atoms via `CONVINTRO`; the cover is the one `SUBDIVIDE` checks), and the branches discharge as follows. In  $\mathcal{D}_-$ , the branch context proves  $h \leq 0$ , so `RELU-NEG`

yields  $y = 0$  (straight from the packaged contract: on  $h \leq 0$  both disjuncts force  $y = 0$ ); the two envelope atoms then reduce, through EQELIM along  $y = 0$ , to degree-1 bound facts on  $[a, 0] — \alpha h + \beta \leq 0$  and  $0 \leq \gamma h + \delta —$  whose degree-1 Bernstein certificates on that cell are *exactly* the checkpoint conditions at  $a$  and at  $0$  (BERNCONE at  $d = 1$ ; on a 1-simplex the degree-1 Bernstein coefficients of an affine gap polynomial are its two endpoint values). Dually in  $\mathcal{D}_+$ : RELU-Pos yields  $y = h$  (from the contract's active disjunct; at the boundary  $h = 0$  the inactive disjunct gives the same  $y = 0 = h$ ), and the envelope atoms reduce to degree-1 facts on  $[0, b] — \alpha h + \beta \leq h$  and  $h \leq \gamma h + \delta —$  whose Bernstein certificates are the checkpoint conditions at  $0$  and at  $b$ . The six side conditions are thus the six distinct endpoint values of the four affine gap polynomials, the kink checkpoints  $\beta \leq 0$  and  $0 \leq \delta$  each shared between their line's two cells. ARITHATOM, NORM, and CUT supply the atom-normalization and stitching plumbing throughout (the RELU-ABOVE section walks a chain of this kind in full). Scope of the rewrite, matching template remark (ii): this two-branch derivation is the canonical *single-entry* story — at larger tensor shapes the sign split is per-entry, so the displayed branch contexts  $h \leq 0$  and  $0 \leq h$  do not jointly cover a mixed-sign tensor and the derivation does not lift; the rule's warrant at every positive size is the direct semantic lemma (Proposition R19.3), per the family convention of remark (iii).

**Proposition R19.3** (semantic warrant). *Suppose the linkage holds, the two premise sequents are semantically valid with a common premise formula, and the eight arithmetic side conditions hold (the strict straddle pair  $a < 0, 0 < b$ , plus the six envelope checkpoints — “the six side conditions” elsewhere in this section always means the envelope six). Then the conclusion sequent — the pinned conjunction  $(\alpha h + \beta) \leq y \wedge y \leq (\gamma h + \delta)$  over the same premise — is semantically valid.*

*Proof.* Fix an admissible valuation  $\sigma$  satisfying  $\Phi$ . The premises, instantiated at  $\sigma$ , eliminate to entrywise bounds: every entry  $p$  of the preactivation tensor satisfies  $a \leq p \leq b$  (a rank-0 constant against a tensor compares against every entry). The linkage extraction (reluLinked\_facts) gives the output tensor at the same shape and, per entry, either  $p \leq 0 \wedge y = 0$  or  $0 \leq p \wedge y = p$ . Fix an entry and take the cases.

*Inactive case* ( $p \leq 0, y = 0$ ; here  $p \in [a, 0]$ ). Lower line:  $\alpha p + \beta \leq 0 = y$  by two-endpoint interpolation on  $[a, 0]$  — the affine function  $\alpha(\cdot) + \beta$  is  $\leq 0$  at  $a$  (checkpoint  $\alpha a + \beta \leq 0$ ) and at  $0$  (checkpoint  $\beta \leq 0$ ), hence on all of  $[a, 0]$  (lirpa\_lower\_neg; the verified proof is an explicit product certificate riding the identity  $(-a)(\alpha p + \beta) + (-p)(-(\alpha a + \beta)) + (p - a)(-\beta) = 0$ : on  $[a, 0]$  the last two products are nonnegative, so the assumed violation  $\alpha p + \beta > 0$  — which, with  $-a > 0$ , makes the first term strictly positive — is impossible in a zero sum). Upper line:  $y = 0 \leq \gamma p + \delta$  likewise from the checkpoints at  $a$  and  $0$  (lirpa\_upper\_neg). *Active case* ( $0 \leq p, y = p$ ; here  $p \in [0, b]$ ). Lower line:  $\alpha p + \beta \leq p = y$  by interpolation on  $[0, b]$  from the checkpoints  $\beta \leq 0$  and  $\alpha b + \beta \leq b$  (lirpa\_lower\_pos). Upper line:  $y = p \leq \gamma p + \delta$  from  $0 \leq \delta$  and  $b \leq \gamma b + \delta$  (lirpa\_upper\_pos).

The conclusion's two atoms evaluate entrywise at the shared shape (the affine terms evaluate to  $\beta + \alpha p$  and  $\delta + \gamma p$  per entry — affineWireTerm\_evalQ), so the four cases assemble into the conjunction. That is sound\_lirpa, whose structure the paragraph mirrors step for step.  $\square$

**Remark R19.4** (three checkpoints suffice). Because relu is affine on each side of  $0$  and  $a < 0 < b$ , an affine line bounds it on  $[a, b]$  iff it bounds it at the three points  $a, 0, b$  — the six side conditions are precisely these six facts (two lines  $\times$  three checkpoints), and equivalently the degree-1 Bernstein certificates of Recipe R19.2. A producer can therefore emit the tightest certifiable envelope for its chosen slopes by solving three scalar inequalities per line — nothing about the rule rewards loose coefficients.

**Remark R19.5** (what the strict straddle buys). With  $a < 0 < b$  the checkpoint conditions read, verbatim, “the line is on the correct side of relu at  $a, 0$ , and  $b$ ” (relu( $a$ ) =  $0$  needs  $a \leq 0$ ; relu( $b$ ) =  $b$  needs  $0 \leq b$ ). Semantic soundness would in fact survive relaxing the strictness: whatever the signs of  $a \leq b$ , the six conditions pin the lower line beneath relu on  $[\min(a, 0), \max(b, 0)] \supseteq [a, b]$  — at  $a$  because  $\alpha a + \beta \leq 0 \leq \text{relu}(a)$  holds unconditionally, and on each of  $[\min(a, 0), 0], [0, \max(b, 0)]$  by the same endpoint interpolation; for the upper line the interval containment does the work (the checks at  $0$  and  $b$  dominate relu on  $[0, \max(b, 0)]$ , the checks at  $a$  and  $0$  dominate it on  $[\min(a, 0), 0]$ ). The rule as adopted nevertheless demands the strict straddle, and reasonably: it pins LIRPA to the genuinely unstable case — a stable neuron rides RELU-Pos or RELU-Neg *exactly*, losing nothing to a relaxation — it keeps both interpolation cells nondegenerate, and it is consumed as stated by the verified interpolation lemmas, whose contradiction products multiply by  $-a$  and  $b$ .

**Remark R19.6** (the conclusion is built, not audited). The conclusion formula is pinned syntactically (lirpaConclusionForm): it is the conjunction of the two comparison atoms over the affine terms affineWireTerm  $\beta \alpha h$  and affineWireTerm  $\delta \gamma h$ , constructed from the payload coefficients — the producer supplies no conclusion shape. A payload field that the checker rebuilds rather than reads is one the payload cannot mis-declare (the PCONSTEXACT section's closedness observation, in conclusion-shape form): no “equivalent” respelling can smuggle in a different wire, comparator, or shape.

Literature: the two-sided affine relaxation of ReLU is the verification community's workhorse — the triangle relaxation [66], its dual/convex-outer form [242], CROWN's adaptive slope choice [246], DeepPoly's abstract-domain rendering [220], and the LIRPA framework that named the family [243]. This rule is the checker-side certificate form: the cited works *find* envelopes; the rule only ever *checks* one, at six rational inequalities.

## Rule 20. ReLU-Pos (admissible rule)

### The rule (Steele metanotation)

as realized in the mechanized development; source row: `rules.toml` — *ReLU-Pos*. The metanotation statement is typeset by hand for notational quality; its mechanized ground truth is the Lean statement below, extracted from the sources at every build of this book and hash-bound. The rule *roster* is machine-checked (every mechanized rule tag round-trips to exactly one catalogue row); the statement *text* is editorial, checked by eye against the extracted Lean beside it.

$$\frac{\Phi \vdash h \geq 0 \quad \text{relu}_{\{h\} \rightarrow \{y\}} \in H}{\Phi \vdash y = h} \text{ReLU-Pos}$$

ReLU-Pos is the exactness rule for the active side of a ReLU: once  $\Phi \vdash h \geq 0$  is proven for the preactivation wire of a cited ReLU application, the output wire is not merely bounded but *equal* —  $\Phi \vdash y = h$ . A producer reaches for it when earlier bound propagation has shown a neuron stably active (a proven lower box bound at or above zero): the lossy affine envelope of LiRPA is replaced by an identity, and the equality feeds EQELIM, so every fact known about  $h$  transports to  $y$  verbatim.

What the checker recomputes, given the payload (premise proof, the two wires): the linkage — the hypernet really contains a packaged ReLU application at exactly these ports, of positive total size (the family's port-lookup side condition, displayed in the LiRPA section); that the premise's conclusion is literally the atom  $h \geq 0$  over the same premise formula; and that the conclusion is literally  $y = h$ . Both atoms are elementwise over the node's tensor shape.

Drop the premise and the rule is false at any entry with  $h < 0$  (there  $y = 0 \neq h$ ). Drop the linkage and  $y$  is an arbitrary wire with no semantic tie to  $h$  — the linkage-free rule is unsound over unlinked wires, and a realization without the port lookup could only be kept sound by rejecting every certificate. The interesting hypothesis is the one that is *not* there: no side condition excludes the boundary  $h = 0$ , because the node's two semantic cases agree at the kink — the proof section makes this the centre of the argument.

**notes** TIER NOTE: the unpacking by case analysis over the sign-split fact discharges the active branch cleanly, but its boundary branch needs the antisymmetry step  $h \leq 0 \wedge h \geq 0 \Rightarrow h = 0$ , and no catalogue rule concludes an equality from a pair of opposite inequalities — so, like PCONSTEXACT, this rule is admissible by *reduction to verified machinery* rather than by a complete catalogue derivation: the shipped warrant is the direct lemma `sound_reluPos`, whose boundary case is one antisymmetry step in the model. The proof section states the enumeration behind that claim.

### Lean statement

The warrant consumes the family linkage extraction (`reluLinked_facts`, displayed in the LiRPA section) and the premise, eliminated entrywise (the elimination lemma is displayed alongside); the payload structure is `PreLUPosData`, quoted in full below.

BernsteinLogic.Soundness . **sound\_reluPos**

## Correspondence (Steele display ↔ Lean)

**reviewer-certified against the displayed texts** The dictionary below is a reviewer-certified statement of how the mechanized statements above interpret the displayed rule: display metavariable  $\mapsto$  Lean binder, each display hypothesis  $\mapsto$  the premise or side condition carrying it, the display conclusion  $\mapsto$  the goal — with any deliberate difference in width between display and mechanization named outright. Certification is recorded as a hash triple over (the displayed cell, the extracted statement texts, this dictionary's own text); if any of the three changes, this block turns amber until a reviewer re-certifies. The correspondence claim itself remains editorial — reviewer-grade, not machine-checked; its machine-checked successor types each soundness statement against the rule as a structured object, and supersedes this block per rule as it lands.

Judgment frame as in Ax; sub-derivation premise as at **WEAKEN**; linkage premise — including the positive-size narrowing hidden under the displayed  $\in$  — exactly as in the **LiRPA** dictionary, the family preamble.

- $h \mapsto \text{preact}; y \mapsto \text{post}; \text{relu}_{\{h\} \rightarrow \{y\}} \in H \mapsto \text{hlink} : \text{reluLinked } H \text{ preact post}$  (payload alias: `PReLUPosData.link`, same proposition).
- premise  $\Phi \vdash h \geq 0 \mapsto \text{ih}$  with `hprempost : premise.post = .atom .ge (.var preact) (.const 0)` — displayed comparator and operand order carried exactly, with no sign-folding (in contrast to the **CONVELIM** family's  $\text{all-}\leq$  build output);  $\Phi$  shared via `hpre`. Payload aliases, same propositions:  $\text{ih} \leftrightarrow \text{premiseProof}$  (over the shared premise),  $\text{hpre} \leftrightarrow \text{preEq}$ ,  $\text{hprempost} \leftrightarrow \text{premisePost}$ .
- conclusion  $\Phi \vdash y = h \mapsto$  the goal under `hpost : seq.post = .atom .eq (.var post) (.var preact)` (payload alias: `conclPost`, same equation) — output wire left, preactivation right, as displayed.

Width note: the certified atoms are elementwise over the cited application's tensor shape (batch semantics, as at **LiRPA**); the boundary  $h = 0$  needs no side condition — the node's two semantic cases agree at the kink, by one antisymmetry step in the model (the commentary and tier note). Beyond the family's linkage gate, neither side is wider: every hypothesis of `sound_reluPos` is consumed.

## Lean verifier receipts

module `BernsteinLogic.Soundness`; bound build `a20d90e66c13...` (bound from receipt `a9c0e34d3e3c9c8c`, 2026-08-03T21:30:36Z). A receipt records that named checking layers accepted a build: (module, compiled-artifact SHA-256, environment SHA-256, checker layers), minted when the checking gate ran; the store receipts attesting the bound build are listed with the layers each run credited. Nothing here asks the reader to trust the store: every layer is an independently runnable program over the quoted sources — rebuild the module and re-run the checkers to reproduce the verdict. Receipts attesting superseded builds credit no layer and are omitted from this rendering (the count of omissions, if any, is noted below).

## HOL verifier receipts

documentary hol-strict CLEAN: theory bern\_tr\_catdata2, 272 theorems, 0 cheat-tagged, 0 nonstandard axioms (whitelist: DISK\_THM; the four bool axioms) — verification run of 2026-07-22 on an isolated build host, against a content-addressed checkout of the exact sources cited here (git blob cd3c1e95...). The proof-object stratum is ported as one mutual datatype family with a mutual wellformedness predicate, exactly as the Lean mutual inductive block; this rule's arm states its entire checkable content — the premise post-form, the family linkage, and the conclusion equation — and the linkage lookup into the hypernet's application list has a ported realization (reluLinkedB, theory bern\_tr\_catdata, 252 theorems, 0 offences, same run). The receipt theorem cited here is the kernel-evaluated pair: an accept over a hypernet carrying the packaged ReLU application, and a refusal over one without it — linkage doing exactly its job. Honest residue: the semantic soundness twin (the Lean development's sound\_reluPos) is not yet ported; the payload/checker layer above is.

HOL receipts are documentary: quoted results of hol-strict runs and census rows from the HOL4 development's build evidence, not minted receipt artefacts. A HOL receipt store (the Lean store's twin) is named future work.

## Proof

Genre: admissible rule (tier 2). The family machinery — the packaged node, the linkage, the two-case semantic fact, and its conservativity warrant — is stated in the LiRPA section's family template and is not restated here.

**Recipe R20.1** (the ReLU-Pos instance). The node, and its intended rewrite over the family's sign-split fact:

$$\frac{\mathcal{T} \triangleright \Phi \vdash h \geq 0 \quad \text{relu}_{\{h\} \rightarrow \{y\}} \in H}{\Phi \vdash y = h} \text{ReLU-Pos} \rightsquigarrow \text{case analysis on } (h \leq 0 \wedge y = 0) \vee (0 \leq h \wedge y = h).$$

The *active* branch discharges cleanly: its context carries the conjunct  $y = h$  (the case disjunct enters the branch premise as one ordered subtree, so two  $\wedge E$  steps reach it), which  $Ax$  and  $\wedge E$  extract — the goal verbatim. The *boundary* branch does not: its context carries  $h \leq 0$  and  $y = 0$ , the premise supplies  $h \geq 0$ , and the goal  $y = h$  now needs the antisymmetry fact  $h = 0$  — which, as **Remark R20.3** shows, no catalogue derivation that withholds this rule itself provides. The rewrite therefore does *not* fully discharge into catalogue nodes; like PCONSTEXACT, the rule is admissible by reduction to verified machinery: the shipped warrant is the direct lemma sound\_reluPos, in which the boundary case is a single antisymmetry step in the model ( $p \leq 0$  from the case,  $0 \leq p$  from the premise, so  $p = 0$  and the two cases agree).

**Proposition R20.2** (semantic warrant). *Suppose the linkage holds and the premise sequent — same premise formula, conclusion the atom  $h \geq 0$  — is semantically valid. Then the sequent concluding  $y = h$  is semantically valid.*

*Proof.* Fix an admissible valuation  $\sigma$  satisfying  $\Phi$ . The premise eliminates entrywise: every entry  $p$  of the preactivation tensor satisfies  $0 \leq p$ . The linkage extraction (reluLinked\_facts) gives the output tensor at the same shape and, per entry, either  $p \leq 0 \wedge y = 0$  or  $0 \leq p \wedge y = p$ . In the second case  $y = p$  is the goal entry. In the first,  $p \leq 0$  meets the premise's  $0 \leq p$ , so  $p = 0$  (antisymmetry — the model step the catalogue lacks) and  $y = 0 = p$ . The conclusion atom is the entrywise equality of the two tensors at their shared shape. That is sound\_reluPos, step for step.  $\square$

*Remark R20.3* (the kink case has no catalogue derivation). The claim in Recipe [R20.1](#) is an enumeration over the catalogue’s equality-capable conclusions. `NORM` and `EQREFL` conclude only canonical-form identities ( $h$  and  $0$  are not canonically equal); `EQSYM`, `EQELIM`, and `ARITHATOM` at the `=` comparator only *transport* equalities already proven; this family and the cell rules conclude equalities only over their packaged applications’ ports; the combination rules (`FARKAS`, `SYZGY`, `PBOUND`, `BERNCONE` with an order predicate) conclude order atoms, never `=`; and `BERNCONE`’s degenerate conic-predicate route would need a region atom pinning  $h$  to the single point  $0$ , which no rule derives — region atoms denote regions of positive-dimensional simplices. The catalogue at large *does* reach the fact, and the route is instructive: over the two-wire hypernet carrying only the linked ReLU application, `ReLU-NEG` (premise  $h \leq 0$ , an `AX` extraction) concludes  $y = 0$ , this rule (premise  $h \geq 0$ ) concludes  $y = h$ , and one `EQELIM` along  $y = h$  rewrites  $y = 0$  into  $h = 0$  — the linked application is itself the antisymmetry oracle, its output forced to agree with both branches at the kink. But the elaboration needs the fact *without the rule being eliminated* — the leaf-first species of the admissible template consumes every rule except that one — and with either envelope rule withheld the supply dries up. Write  $d(t = u)$  for the canonical form of  $t - u$ , and consider a smallest derivation, withholding one envelope rule, that concludes an equality atom with  $d$  not a polynomial multiple of the surviving port difference ( $y$  if `ReLU-Pos` is withheld with `ReLU-NEG`’s  $y = 0$  surviving;  $y - h$  mirrored). Its final step cannot be the surviving port conclusion or a canonical-form identity ( $d$  a multiple of the port difference, respectively  $0$ ); not `EQSYM`, the zero-form respelling, or `EQELIM` transport (each changes  $d$  by a sign or by polynomial multiples of a previously concluded equality’s own  $d$  — a smaller derivation, hence a permitted multiple); not a closed ground fact ( $d = 0$ , the constants being exactly evaluated); not a combination or region rule (order and region conclusions only); and not a structural or case-analysis step, which only re-exposes an equality already concluded, or sitting in a premise set — the root premises ( $h \leq 0 \wedge h \geq 0$ , at either spelling) contain no equality, premise sets grow only by `CUT` formulas and case disjuncts concluded or contained in smaller derivations, and a case split whose smuggled disjunct carries the target is idle: its sibling branch must conclude the same target without it, a smaller offender. The target  $d(h = 0) = h$  is a multiple of neither  $y$  nor  $y - h$ , so  $h \leq 0 \wedge h \geq 0 \vdash h = 0$  has no `ReLU-Pos`-free derivation (nor, mirrored, a `ReLU-NEG`-free one), and the boundary branch cannot discharge into nodes. This is not a defect to repair but a fact about where the calculus keeps its arithmetic: an elaboration can source order antisymmetry only from the verified model step, one line of `sound_reluPos`, rather than from a rule every certificate would pay wire format for.

*Remark R20.4* (what the premise is for). Without  $\Phi \vdash h \geq 0$  the rule is false at any entry with  $h < 0$ : there the node’s semantics forces  $y = 0 \neq h$ . The premise is consumed *entrywise* — a tensor-shaped preactivation must be proven nonnegative in every entry, which is what a rank- $0$  constant against a tensor atom asserts. No side condition excludes the boundary  $h = 0$ , and none is needed: the two semantic cases agree there, which is exactly the antisymmetry step above.

## Rule 21. ReLU-NEG (admissible rule)

### The rule (Steele metanotation)

as realized in the mechanized development; source row: `rules.toml` — *ReLU-Neg*. The metanotation statement is typeset by hand for notational quality; its mechanized ground truth is the Lean statement below, extracted from the sources at every build of this book and hash-bound. The rule *roster* is machine-checked (every mechanized rule tag round-trips to exactly one catalogue row); the statement *text* is editorial, checked by eye against the extracted Lean beside it.

$$\frac{\Phi \vdash h \leq 0 \quad \text{relu}_{\{h\} \rightarrow \{y\}} \in H}{\Phi \vdash y = 0} \text{ReLU-NEG}$$

ReLU-NEG is the exactness rule for the inactive side of a ReLU, ReLU-Pos's mirror: once  $\Phi \vdash h \leq 0$  is proven for the preactivation wire of a cited ReLU application, the output is pinned to a constant —  $\Phi \vdash y = 0$ . A producer reaches for it when bound propagation has shown a neuron stably inactive (a proven upper box bound at or below zero): the neuron is dead on the region of interest, and the equality lets EQELIM rewrite  $y$  to the literal constant 0 downstream — dead-neuron elimination in certificate form, at the rank-0 instances the constant-sided transport gate admits (the family's shape-scope remark).

What the checker recomputes, given the payload (premise proof, the two wires): the linkage — a packaged ReLU application at exactly these ports, of positive total size (the family's port-lookup side condition, displayed in the LiRPA section); that the premise's conclusion is literally the atom  $h \leq 0$  over the same premise formula; and that the conclusion is literally  $y = 0$ . Both atoms are elementwise over the node's tensor shape.

Drop the premise and the rule is false at any entry with  $h > 0$  (there  $y = h \neq 0$ ). Drop the linkage and an arbitrary wire is asserted zero. As with ReLU-Pos, the boundary  $h = 0$  needs no exclusion: both semantic cases of the node force  $y = 0$  there.

**notes** TIER NOTE: as for ReLU-Pos, and for the mirrored reason — the unpacking's active branch would need  $h = 0$  from  $h \geq 0 \wedge h \leq 0$ , an antisymmetry step no catalogue rule provides — the rule is admissible by reduction to verified machinery: the shipped warrant is the direct lemma `sound_reluNeg`. The enumeration argument is stated once, in the ReLU-Pos proof section.

### Lean statement

The warrant consumes the family linkage extraction (`reluLinked_facts`, displayed in the LiRPA section) and the premise, eliminated entrywise (the elimination lemma is displayed alongside); the payload structure is `PreLUNegData`, quoted in full below.

BernsteinLogic.Soundness . **sound\_reluNeg**

statement bound

```
/-- ReLU-Neg: from `Φ ⊢ h ≤ 0` conclude `Φ ⊢ y = 0` — on each entry the
premise forces the nonnegative case's input to 0, where both cases
agree. -/
theorem sound_reluNeg {H : Hypernet} {seq premise : Sequent}
  {preact post : Wire}
  (ih : premise.semanticallyValid H)
  (hlink : reluLinked H preact post)
  (hpre : seq.pre = premise.pre)
  (hprePost : premise.post = .atom .le (.var preact) (.const 0))
  (hpost : seq.post = .atom .eq (.var post) (.const 0)) :
  seq.semanticallyValid H

## Correspondence (Steele display $\leftrightarrow$ Lean)

**reviewer-certified against the displayed texts** The dictionary below is a reviewer-certified statement of how the mechanized statements above interpret the displayed rule: display metavariable  $\mapsto$  Lean binder, each display hypothesis  $\mapsto$  the premise or side condition carrying it, the display conclusion  $\mapsto$  the goal — with any deliberate difference in width between display and mechanization named outright. Certification is recorded as a hash triple over (the displayed cell, the extracted statement texts, this dictionary's own text); if any of the three changes, this block turns amber until a reviewer re-certifies. The correspondence claim itself remains editorial — reviewer-grade, not machine-checked; its machine-checked successor types each soundness statement against the rule as a structured object, and supersedes this block per rule as it lands.

Judgment frame as in Ax; sub-derivation premise as at WEAKEN; linkage premise — including the positive-size narrowing hidden under the displayed  $\in$  — exactly as in the LiRPA dictionary, the family preamble.

- $h \mapsto \text{preact}; y \mapsto \text{post}; \text{relu}_{\{h\} \rightarrow \{y\}} \in H \mapsto \text{hlink} : \text{reluLinked } H \text{ preact post}$  (payload alias: `PReLUegData.link`, same proposition).
- premise  $\Phi \vdash h \leq 0 \mapsto \text{ih}$  with `hprempost : premise.post = .atom .le (.var preact) (.const 0)` — displayed comparator and operand order carried exactly;  $\Phi$  shared via `hpre`. Payload aliases, same propositions:  $\text{ih} \leftrightarrow \text{premiseProof}$  (over the shared premise),  $\text{hpre} \leftrightarrow \text{preEq}$ ,  $\text{hprempost} \leftrightarrow \text{premisePost}$ .
- conclusion  $\Phi \vdash y = 0 \mapsto$  the goal under `hpost : seq.post = .atom .eq (.var post) (.const 0)` (payload alias: `conclPost`, same equation) — output wire left, constant right, as displayed.

Width note: certified atoms elementwise over the cited application's tensor shape (batch semantics, as at LiRPA); the boundary  $h = 0$  is again condition-free — the mirrored antisymmetry step of the tier note. Beyond the family's linkage gate, neither side is wider: every hypothesis of `sound_reluNeg` is consumed.

## Lean verifier receipts

module BernsteinLogic.Soundness; bound build a20d90e66c13... (bound from receipt a9c0e34d3e3c9c8c, 2026-08-03T21:30:36Z). A receipt records that named checking layers accepted a build: (module, compiled-artifact SHA-256, environment SHA-256, checker layers), minted when the checking gate ran; the store receipts attesting the bound build are listed with the layers each run credited. Nothing here asks the reader to trust the store: every layer is an independently runnable program over the quoted sources — rebuild the module and re-run the checkers to reproduce the verdict. Receipts attesting superseded builds credit no layer and are omitted from this rendering (the count of omissions, if any, is noted below).

```

**HOL verifier receipts**

documentary hol-strict CLEAN: theory bern\_tr\_catdata2, 272 theorems, 0 cheat-tagged, 0 nonstandard axioms (whitelist: DISK\_THM; the four bool axioms) — verification run of 2026-07-22 on an isolated build host, against a content-addressed checkout of the exact sources cited here (git blob cd3c1e95...). The proof-object stratum is ported as one mutual datatype family with a mutual wellformedness predicate, exactly as the Lean mutual inductive block; this rule's arm states its entire checkable content — the premise post-form, the family linkage, and the zero-clamp conclusion equation — and the linkage lookup into the hypernet's application list has a ported realization (reluLinkedB, theory bern\_tr\_catdata, 252 theorems, 0 offences, same run). The receipt theorem cited here is the kernel-evaluated pair: an accept over a hypernet carrying the packaged ReLU application, and a wrong-conclusion refusal. Honest residue: the semantic soundness twin (the Lean development's sound\_reluNeg) is not yet ported; the payload/checker layer above is.

HOL receipts are documentary: quoted results of hol-strict runs and census rows from the HOL4 development's build evidence, not minted receipt artefacts. A HOL receipt store (the Lean store's twin) is named future work.

**Proof**

Genre: admissible rule (tier 2). The family machinery is stated in the LiRPA section's family template; ReLU-Pos is this rule's mirror, and the shared boundary argument is stated there.

**Recipe R21.1** (the ReLU-NEG instance). The node, and its intended rewrite over the family's sign-split fact:

$$\frac{\mathcal{T} \triangleright \Phi \vdash h \leq 0 \quad \text{relu}_{\{h\} \rightarrow \{y\}} \in H}{\Phi \vdash y = 0} \text{ReLU-NEG} \rightsquigarrow \text{case analysis on } (h \leq 0 \wedge y = 0) \vee (0 \leq h \wedge y = h).$$

The *inactive* branch discharges cleanly: its context carries the conjunct  $y = 0$  (one ordered subtree of the branch premise; two  $\wedge E$  steps), extracted by Ax and  $\wedge E$  — the goal verbatim. The *boundary* branch is the mirror of ReLU-Pos's: its context carries  $0 \leq h$  and  $y = h$ , the premise supplies  $h \leq 0$ , and the goal  $y = 0$  needs  $h = 0$  — the antisymmetry fact that no catalogue derivation withholding this rule itself provides (the enumeration argument, covering both withheld orientations, is stated once, as **Remark R20.3** in the ReLU-Pos section). The rule is therefore admissible by reduction to verified machinery: the shipped warrant is the direct lemma sound\_reluNeg, whose boundary case is the same one-line antisymmetry step in the model.

**Proposition R21.2** (semantic warrant). *Suppose the linkage holds and the premise sequent — same premise formula, conclusion the atom  $h \leq 0$  — is semantically valid. Then the sequent concluding  $y = 0$  is semantically valid.*

*Proof.* Fix an admissible valuation  $\sigma$  satisfying  $\Phi$ . The premise eliminates entrywise: every entry  $p$  of the preactivation tensor satisfies  $p \leq 0$ . The linkage extraction (reluLinked\_facts) gives, per entry, either  $p \leq 0 \wedge y = 0$  — the goal entry directly — or  $0 \leq p \wedge y = p$ , in which case  $p = 0$  by antisymmetry against the premise, so  $y = p = 0$ . The conclusion atom compares the output tensor entrywise against the rank-0 constant 0. That is sound\_reluNeg, step for step.  $\square$

**Remark R21.3** (what the premise is for, and what the rule feeds). Without  $\Phi \vdash h \leq 0$  the rule is false at any entry with  $h > 0$  (there  $y = h \neq 0$ ). Downstream, the conclusion differs from ReLU-Pos's in kind:  $y = 0$  pins the output to a *literal constant*, so EqELIM can rewrite  $y$  away — dead-neuron elimination inside a certificate — at the rank-0 instances the transport gate admits (a constant-sided equality rides EqELIM's shared-broadcast-shape condition; the family's shape-scope remark, ReLU-NN section), after which ground arithmetic on the constant rides PCONSTEXACT.

| proof step                           | formal anchor                                    |

## Rule 22. ReLU-NN (admissible rule)

### The rule (Steele metanotation)

as realized in the mechanized development; source row: `rules.toml` — *ReLU-NN*. The metanotation statement is typeset by hand for notational quality; its mechanized ground truth is the Lean statement below, extracted from the sources at every build of this book and hash-bound. The rule *roster* is machine-checked (every mechanized rule tag round-trips to exactly one catalogue row); the statement *text* is editorial, checked by eye against the extracted Lean beside it.

$$\frac{\text{relu}_{\{h\} \rightarrow \{y\}} \in H}{\Phi \vdash y \geq 0} \text{ReLU-NN}$$

ReLU-NN is the range fact: the output wire of a cited ReLU application is nonnegative,  $\Phi \vdash y \geq 0$ , with no proof premises at all —  $\Phi$  is arbitrary (the premise-free convention shared with NORM and PCONSTEXACT). It is the first thing a producer knows about every ReLU output: the lower half of every output box starts here, before any information about the preactivation exists, and together with ReLU-ABOVE it yields the exact pointwise lower envelope of the activation ( $y \geq \max(0, h)$ , as two atoms).

What the checker recomputes is nearly everything, because there is nearly nothing: the linkage — the hypernet really contains a packaged ReLU application at exactly these ports, of positive total size (the family's port-lookup side condition, displayed in the LiRPA section) — and that the conclusion is literally the atom  $y \geq 0$ , elementwise over the node's tensor shape.

The linkage is the only hypothesis, and dropping it is the whole failure mode: an arbitrary wire asserted nonnegative, against an arbitrary premise — the linkage-free rule is unsound over unlinked wires, and a realization without the port lookup could only be kept sound by rejecting every certificate. The positive-size gate inside the linkage keeps even the vacuous-surface corner unciteable (a size-zero node satisfies every elementwise atom trivially; the linkage refuses it at the source).

**notes** This is the family's cleanest unpacking: the case analysis over the sign-split fact discharges *both* branches into catalogue nodes — the inactive branch's leaf is the ground fact  $0 \geq 0$ , which rides PCONSTEXACT (the one rule that can state a closed ground fact). The proof section displays the full intended derivation (its case-closing disjunction elimination is the context-carrying form — a satellite theorem today, so the display is an elaboration blueprint rather than an emittable certificate), and states its shape scope honestly: the constant-sided equality transport type-checks at rank-0 instances, and the shape-general warrant is the direct lemma.

### Lean statement

The warrant consumes the family linkage extraction (`reluLinked_facts`, displayed in the LiRPA section): each output entry is either 0 or a copy of a nonnegative input entry. The payload structure, `PreLUNNData` — quoted in full below — carries no premise field.

BernsteinLogic.Soundness . **sound\_reluNN**

statement bound

```
/-- ReLU-NN: `Φ ⊢ y ≥ 0`, premise-free — every entry of the packaged
output is 0 or a nonnegative copy of the input entry. (A review finding
exhibited the rule as unsound over unbound wires; the linkage is the repair.) -/
theorem sound_reluNN {H : Hypernet} {seq : Sequent} {preact post : Wire}
  (hlink : reluLinked H preact post)
  (hpost : seq.post = .atom .ge (.var post) (.const 0)) :
  seq.semanticallyValid H
```

BernsteinLogic.Core.Catalogue . **PreLUNNData**

definition bound

```
inductive PreLUNNData : Hypernet → Sequent → Type where
| mk (H : Hypernet) (seq : Sequent)
  (preact post : Wire)

  (conclPost : seq.post = .atom .ge (.var post) (.const 0))
  : PreLUNNData H seq
```

### Correspondence (Steele display ↔ Lean)

**a bound Lean statement CHANGED since certification — re-review and re-certify** The dictionary below is a reviewer-certified statement of how the mechanized statements above interpret the displayed rule: display metavariable  $\mapsto$  Lean binder, each display hypothesis  $\mapsto$  the premise or side condition carrying it, the display conclusion  $\mapsto$  the goal — with any deliberate difference in width between display and mechanization named outright. Certification is recorded as a hash triple over (the displayed cell, the extracted statement texts, this dictionary's own text); if any of the

three changes, this block turns amber until a reviewer re-certifies. The correspondence claim itself remains editorial — reviewer-grade, not machine-checked; its machine-checked successor types each soundness statement against the rule as a structured object, and supersedes this block per rule as it lands.

Judgment frame as in Ax; linkage premise — including the positive-size narrowing hidden under the displayed  $\in$  — exactly as in the LiRPA dictionary, the family preamble.

- $h \mapsto \text{preact}; y \mapsto \text{post}; \text{relu}_{\{h\} \rightarrow \{y\}} \in H \mapsto \text{hlink} : \text{reluLinked } H \text{ preact post}$  (payload alias: `PreLUNNData.link`, same proposition). The display's universality over the preactivation — no premise constrains  $h$  — is carried by the linkage alone: `preact` occurs in no other hypothesis (the roster note records that the appendix payload named only the output wire — the certified linkage names both ports).
- premise-freeness  $\mapsto$  silence, the `PConstExact` representation: the precondition component of `seq : Sequent` is unconstrained by any hypothesis, so the statement holds under arbitrary premises  $\Phi$ .
- conclusion  $\Phi \vdash y \geq 0 \mapsto$  the goal under `hpost : seq.post = .atom .ge (.var post) (.const 0)` (payload alias: `conclPost`, same equation) — displayed comparator and operand order carried exactly.

Width note: certified atoms elementwise over the cited application's tensor shape (batch semantics, as at LiRPA). Beyond the family's linkage gate, neither side is wider: both hypotheses of `sound_reluNN` are consumed, and nothing else is stated.

## Lean verifier receipts

module `BernsteinLogic.Soundness`; bound build `a20d90e66c13...` (bound from receipt `a9c0e34d3e3c9c8c`, 2026-08-03T21:30:36Z). A receipt records that named checking layers accepted a build: (module, compiled-artifact SHA-256, environment SHA-256, checker layers), minted when the checking gate ran; the store receipts attesting the bound build are listed with the layers each run credited. Nothing here asks the reader to trust the store: every layer is an independently runnable program over the quoted sources — rebuild the module and re-run the checkers to reproduce the verdict. Receipts attesting superseded builds credit no layer and are omitted from this rendering (the count of omissions, if any, is noted below).

## HOL verifier receipts

**documentary** hol-strict CLEAN: theory bern\_tr\_catdata2, 272 theorems, 0 cheat-tagged, 0 nonstandard axioms (whitelist: DISK\_THM; the four bool axioms) — verification run of 2026-07-22 on an isolated build host, against a content-addressed checkout of the exact sources cited here (git blob cd3c1e95...). The proof-object stratum is ported as one mutual datatype family with a mutual wellformedness predicate, exactly as the Lean mutual inductive block; this premise-free rule's arm states its entire checkable content — the family linkage plus the nonnegativity conclusion equation — and the linkage lookup into the hypernet's application list has a ported realization (reluLinkedB, theory bern\_tr\_catdata, 252 theorems, 0 offences, same run). The receipt theorem cited here is the kernel-evaluated accept/refusal pair for the arm. Honest residue: the semantic soundness twin (the Lean development's sound\_reluNN) is not yet ported; the payload/checker layer above is.

HOL receipts are documentary: quoted results of hol-strict runs and census rows from the HOL4 development's build evidence, not minted receipt artefacts. A HOL receipt store (the Lean store's twin) is named future work.

## Proof

Genre: admissible rule (tier 2). The family machinery is stated in the LiRPA section's family template. This rule is premise-free:  $\Phi$  is arbitrary and never consulted (the NORM convention).

**Recipe R22.1** (the ReLU-NN instance — the full unpacking). The node:

$$\frac{\text{relu}_{\{h\} \rightarrow \{y\}} \in H}{\Phi \vdash y \geq 0} \text{ReLU-NN} \quad \rightsquigarrow \quad \text{case analysis on } (h \leq 0 \wedge y = 0) \vee (0 \leq h \wedge y = h),$$

and both branches discharge into catalogue nodes — the family's cleanest unpacking. *Inactive branch* (context carries  $y = 0$ ):

1.  $\vdash 0 \geq 0$  — PCONSTEXACT, the closed exact ground fact (the leaf that rule exists to state: no other catalogue rule concludes a closed ground fact);
2.  $\Phi_- \vdash y = 0$  —  $\text{Ax} + \wedge\text{E}$  from the branch context (the case disjunct enters as one ordered subtree; two  $\wedge\text{E}$  steps); then  $\Phi_- \vdash 0 = y$  by EQSYM;
3.  $\Phi_- \vdash y \geq 0$  — EQELIM along  $0 = y$ , transporting  $\Psi[a := 0] = (0 \geq 0)$  (step 1, weakened) to  $\Psi[a := y]$ , where  $\Psi = (a \geq 0)$ .

*Active branch* (context carries  $0 \leq h$  and  $y = h$ ): the context's sign atom is extracted ( $\text{Ax} + \wedge\text{E}$ ) and re-oriented to  $h \geq 0$  by the bound node's polarity-flip reading (PBOUND, reading (G): the single component  $0 \leq h$  with weight 1, canonical polynomial  $c = -h$ , read as  $e \geq 0$  with  $e = h$  — one node of the toolkit whose longer chains the ReLU-ABOVE section walks); EQSYM flips the context's  $y = h$  to  $h = y$ , and EQELIM along  $h = y$  (an equality between two wires of the node's one shared shape) transports it to  $y \geq 0$ .  $\vee\text{E}$  in its context-carrying form — today a satellite theorem, not a core constructor (the split rule's section prices exactly this), so what follows is the intended elaboration, emittable when that constructor lands — closes the case analysis, and CUT stitches the sign-split fact into place.

**Remark R22.2** (the shape scope of the displayed derivation). The realized EQELIM carries a broadcast-shape side condition (its section documents the counterexample that forced it): both sides of the transported equality must share a broadcast shape. Step 3's equality  $0 = y$  has a rank-0 constant on one side, so the displayed transport type-checks where the output wire is rank-0 — at tensor-shaped instances that step is stopped by the gate, and the family's realized warrant does not route through the derivation at all: it is the direct lemma sound\_reluNN, shape-general, via the linkage extraction. (Wire-to-wire transports such as the active branch's  $h = y$  are unaffected: the linkage forces one shared shape.) The derivation above is thus the intended admissibility story at scalar instances — intended, since its case-closing step awaits the constructor named at its step — and the reduction-to-verified-machinery story, the PCONSTEXACT pattern stated in the family template, is the standing warrant at every shape either way.

**Proposition R22.3** (semantic warrant). *If the linkage holds, the sequent concluding  $y \geq 0$  is semantically valid over any premise formula  $\Phi$ .*

*Proof.* Fix an admissible valuation  $\sigma$  ( $\sigma \models \Phi$  is taken but never consulted — the rule is premise-free). The linkage extraction (reluLinked\_facts) gives the output tensor and, per entry, either  $y = 0$  or  $y = p$  with  $0 \leq p$ ; in both cases  $0 \leq y$ . The conclusion atom compares the output tensor entrywise against the rank-0 constant 0. That is sound\_reluNN, step for step.  $\square$

**Remark R22.4** (the only hypothesis). The linkage is the rule's sole side condition — the conclusion-shape check beside it is a reconstruction pin, not a droppable hypothesis: the checker rebuilds the atom  $y \geq 0$  rather than trusting it, so “dropping” the pin merely re-addresses the rule at a conclusion it never concluded. Dropping the linkage is the whole failure mode: an arbitrary wire asserted nonnegative against an arbitrary premise. Its positive-size gate additionally keeps the vacuous corner unciteable — a size-zero node satisfies every elementwise atom trivially, and a fact no valuation can falsify must not enter a derivation (the family template's hygiene remark).

### proof step

Recipe R22.1 warrant  
family linkage extraction  
ground-fact leaf (step 1)  
payload structure

### formal anchor

sound\_reluNN  
reluLinked\_facts (see the LiRPA section)  
sound\_pConstExact (the PCONSTEXACT section)  
PRELUNNData (two wires, linkage — no premise field)

## Rule 23. ReLU-ABOVE (admissible rule)

### The rule (Steele metanotation)

as realized in the mechanized development; source row: `rules.toml` — *ReLU-Above*. The metanotation statement is typeset by hand for notational quality; its mechanized ground truth is the Lean statement below, extracted from the sources at every build of this book and hash-bound. The rule *roster* is machine-checked (every mechanized rule tag round-trips to exactly one catalogue row); the statement *text* is editorial, checked by eye against the extracted Lean beside it.

$$\frac{\text{relu}_{\{h\} \rightarrow \{y\}} \in H}{\Phi \vdash y \geq h} \text{ReLU-ABOVE}$$

ReLU-ABOVE is the identity minorant: the output wire of a cited ReLU application dominates its preactivation,  $\Phi \vdash y \geq h$ , with no proof premises —  $\Phi$  arbitrary, the premise-free convention. Together with ReLU-NN it gives the exact pointwise lower envelope of the activation as two always-available atoms ( $y \geq 0$  and  $y \geq h$ ); a producer needs no box knowledge at all to emit either. Upper bounds are different in kind — no affine upper bound on the activation exists without a box, which is why the upper side of the family lives in LiRPA behind two box premises.

What the checker recomputes: the linkage — the hypernet really contains a packaged ReLU application at exactly these ports, of positive total size (the family's port-lookup side condition, displayed in the LiRPA section) — and that the conclusion is literally the atom  $y \geq h$ , elementwise over the node's tensor shape.

The linkage is the only hypothesis; without it, two arbitrary wires are asserted ordered. Entrywise the fact is immediate from the node's two-case semantics: on the inactive branch  $y = 0 \geq h$  (there  $h \leq 0$ ), on the active branch  $y = h$ .

**notes** The proof section uses this rule's derivation as the family's worked example of atom-orientation plumbing: its inactive branch discharges into catalogue nodes through a chain of a bound-node polarity flip, a NORM identity, an ARITHATOM fold, and two EQELIM transports — a faithful specimen of what “one node unpacks to many” means in practice.

### Lean statement

The warrant consumes the family linkage extraction (`reluLinked_facts`, displayed in the LiRPA section): entrywise,  $y = 0 \geq h$  on the inactive case and  $y = h$  on the active one. The payload structure, `PRELUAboveData` — quoted in full below — carries no premise field.

`BernsteinLogic.Soundness . sound_reluAbove`

statement bound

```
-- ReLU-Above: `Φ ⊢ y ≥ h`, premise-free — entrywise, `y = 0 ≥ h` on
the nonpositive case and `y = h` on the nonnegative one. -/
theorem sound_reluAbove {H : Hypernet} {seq : Sequent} {preact post : Wire}
  (hlink : reluLinked H preact post)
  (hpost : seq.post = .atom .ge (.var post) (.var preact)) :
  seq.semanticallyValid H
```

`BernsteinLogic.Core.Catalogue . PRELUAboveData`

definition bound

```
inductive PRELUAboveData : Hypernet → Sequent → Type where
| mk (H : Hypernet) (seq : Sequent)
  (preact post : Wire)
  (link : reluLinked H preact post)
  (conclPost : seq.post = .atom .ge (.var post) (.var preact))
  : PRELUAboveData H seq
```

### Correspondence (Steele display ↔ Lean)

**reviewer-certified against the displayed texts** The dictionary below is a reviewer-certified statement of how the mechanized statements above interpret the displayed rule: display metavariable  $\mapsto$  Lean binder, each display hypothesis  $\mapsto$  the premise or side condition carrying it, the display conclusion  $\mapsto$  the goal — with any deliberate difference in width between display and mechanization named outright. Certification is recorded as a hash triple over (the displayed cell, the extracted statement texts, this dictionary's own text); if any of the three changes, this block turns amber until a reviewer re-certifies. The correspondence claim itself remains editorial — reviewer-grade, not machine-checked; its machine-checked successor types each soundness statement against the rule as a structured object, and supersedes this block per rule as it lands.

Judgment frame as in Ax; linkage premise — including the positive-size narrowing hidden under the displayed  $\in$  — exactly as in the LiRPA dictionary, the family preamble.

- $h \mapsto \text{preact}; y \mapsto \text{post}; \text{relu}_{\{h\} \rightarrow \{y\}} \in H \mapsto \text{hlink} : \text{reluLinked } H \text{ preact post}$  (payload alias: `PRELUAboveData.Link`, same proposition).
- premise-freeness  $\mapsto$  silence, the `PConstExact` representation: the precondition component of `seq : Sequent` is unconstrained by any hypothesis, so the statement holds under arbitrary premises  $\Phi$  — the display's universality over the preactivation rides the linkage, as at `ReLU-NN`.
- conclusion  $\Phi \vdash y \geq h \mapsto$  the goal under `hpost : seq.post = .atom .ge (.var post) (.var preact)` (payload alias: `conclPost`, same equation) — output wire left, preactivation right, as displayed; the only two-wire atom among the family's premise-free conclusions, so this dictionary is where the shared shape of the two tensors (from the linkage extraction) is load-bearing rather than convenient.

Width note: certified atoms elementwise over the cited application's tensor shape (batch semantics, as at `LiRPA`). Beyond the family's linkage gate, neither side is wider: both hypotheses of `sound_reluAbove` are consumed, and nothing else is stated.

## HOL verifier receipts

**documentary** hol-strict CLEAN: theory bern\_tr\_catdata2, 272 theorems, 0 cheat-tagged, 0 nonstandard axioms (whitelist: DISK\_THM; the four bool axioms) — verification run of 2026-07-22 on an isolated build host, against a content-addressed checkout of the exact sources cited here (git blob cd3c1e95...). The proof-object stratum is ported as one mutual datatype family with a mutual wellformedness predicate, exactly as the Lean mutual inductive block; this premise-free rule's arm states its entire checkable content — the family linkage plus the output-dominates-preactivation conclusion equation — and the linkage lookup into the hypernet's application list has a ported realization (reluLinkedB, theory bern\_tr\_catdata, 252 theorems, 0 offences, same run). The receipt theorem cited here is the kernel-evaluated accept/refusal pair for the arm. Honest residue: the semantic soundness twin (the Lean development's sound\_reluAbove) is not yet ported; the payload/checker layer above is.

HOL receipts are documentary: quoted results of hol-strict runs and census rows from the HOL4 development's build evidence, not minted receipt artefacts. A HOL receipt store (the Lean store's twin) is named future work.

## Proof

Genre: admissible rule (tier 2). The family machinery is stated in the LiRPA section's family template. This rule is premise-free:  $\Phi$  is arbitrary and never consulted.

**Recipe R23.1** (the ReLU-ABOVE instance — worked plumbing). The node:

$$\frac{\text{relu}_{\{h\} \rightarrow \{y\}} \in H}{\Phi \vdash y \geq h} \quad \text{ReLU-ABOVE} \quad \rightsquigarrow \quad \text{case analysis on } (h \leq 0 \wedge y = 0) \vee (0 \leq h \wedge y = h).$$

We walk the *inactive* branch in full — the family's honest specimen of what “one node unpacks to many” means in catalogue practice. Context  $\Phi_-$  carries  $h \leq 0$  and  $y = 0$ ; the goal is  $y \geq h$ .

1.  $\Phi_- \vdash h \leq 0$  —  $\text{Ax} + \wedge\text{E}$  (the case disjunct enters as one ordered subtree; two  $\wedge\text{E}$  steps).
2.  $\Phi_- \vdash -h \geq 0$  — the bound node's polarity-flip reading (PBOUND, reading (G)): the combination is the single component  $h \leq 0$  with weight 1, canonical polynomial  $c = h$ , read as  $e \geq 0$  with  $e = -h$ .
3.  $\Phi_- \vdash (-h) = (0 - h)$  — NORM: equal monomial canonical forms over  $\mathbb{Q}$ , same wires, shared broadcast shape.
4.  $\Phi_- \vdash (0 - h) \geq 0$  — EQELIM along step 3's equality (both sides shaped alike — the transport gate is met), rewriting step 2's atom.
5.  $\Phi_- \vdash 0 \geq h$  — ARITHATOM (fold): from  $(t_1 - t_2) \bowtie 0$  to  $t_1 \bowtie t_2$  at  $t_1 = 0, t_2 = h, \bowtie = \geq$ .
6.  $\Phi_- \vdash 0 = y$  — EQSYM on the context's  $y = 0$ ; then  $\Phi_- \vdash y \geq h$  — EQELIM along  $0 = y$  at  $\Psi = (a \geq h)$ .

The *active* branch (context  $0 \leq h, y = h$ ) derives  $h \geq h$  by the same pattern, spelled at the same grain: NORM gives  $(h - h) = 0$ , whence  $0 = (h - h)$  by EQSYM; PCONSTEXACT supplies the ground fact  $0 \geq 0$ , weakened into the branch context; EQELIM along  $0 = (h - h)$  transports it to  $(h - h) \geq 0$ , and ARITHATOM folds that to  $h \geq h$  — then EQSYM on the context's  $y = h$  and EQELIM along  $h = y$  (wire-to-wire, one shared shape) close the goal. Six arithmetic-plumbing nodes in the inactive branch — PBOUND, NORM, EQELIM, ARITHATOM, EQSYM, EQELIM; the extraction's Ax and  $\wedge\text{E}$  steps aside — to move one minus sign across a comparator: this is why the family rules exist as single nodes, and why the wire format prices them.

**Remark R23.2** (shape scope). Step 6 of the inactive branch and the active branch's route through  $(h - h) = 0$  transport along equalities with a rank-0 constant side, so the displayed derivation type-checks at rank-0 instances (step 4's transport along  $(-h) = (0 - h)$  is wire-shaped on both sides — the constant 0 sits *inside* the term  $0 - h$  — and is unaffected); the shape-general warrant is the direct lemma, exactly as **Remark R22.2** in the ReLU-NN section states for the whole family.

**Proposition R23.3** (semantic warrant). *If the linkage holds, the sequent concluding  $y \geq h$  is semantically valid over any premise formula  $\Phi$ .*

*Proof.* Fix an admissible valuation  $\sigma$ . The linkage extraction (reluLinked\_facts) gives both tensors at one shared shape and, per entry, either  $p \leq 0 \wedge y = 0$  — whence  $y = 0 \geq p$  — or  $y = p$  — whence  $y \geq p$  reflexively. The conclusion atom compares the two tensors entrywise at their shared shape. That is sound\_reluAbove, step for step.  $\square$

**Remark R23.4** (the exact lower envelope, premise-free). Together with ReLU-NN this rule states the exact pointwise lower envelope of the activation,  $y \geq \max(0, h)$ , as two atoms a producer can emit with *no* box knowledge whatsoever — exact in that the bound is attained:  $\max(0, h)$  is the activation's value, so no sound lower bound can improve on the pair. The asymmetry with the upper side is structural, not an artefact: no affine function dominates  $\max(0, h)$  on all of  $\mathbb{Q}$  (a candidate with positive slope dives below 0 as  $h \rightarrow -\infty$ ; one with slope  $\leq 0$  falls below  $h$  as  $h \rightarrow +\infty$ ) — so upper bounds require a box and live in LiRPA.

### proof step

sound\_pConstExact (the PCONSTEXACT section)  
PReLUAboveData (two wires, linkage — no premise field)

## Rule 24. CELL-IN-INTERIOR (admissible rule)

### The rule (Steele metanotation)

as realized in the mechanized development; source row: `rules.toml` — *Cell-In-Interior*. The metanotation statement is typeset by hand for notational quality; its mechanized ground truth is the Lean statement below, extracted from the sources at every build of this book and hash-bound. The rule *roster* is machine-checked (every mechanized rule tag round-trips to exactly one catalogue row); the statement *text* is editorial, checked by eye against the extracted Lean beside it.

$$\frac{\Phi \vdash \bigwedge_v \lambda_v^{C_i}(x) \bowtie_v^\circ 0 \text{ (strict barycentric interior atoms, flat vertex order; } < \text{ for extended } v, > \text{ for core } v) \quad \text{cell}[\Sigma]_{\{x\} \rightarrow \{b_1, \dots, b_N\}} \in H}{\Phi \vdash b_i = 1 \wedge \bigwedge_{j \neq i} b_j = 0} \quad \text{CELL-IN-INTERIOR}$$

CELL-IN-INTERIOR is one of the two rules that read the cell primitive — the calculus's only source of disjunction. A cell application  $\text{cell}[\Sigma]_{\{x\} \rightarrow \{b_1, \dots, b_N\}}$  tabulates which cell of a simplicial decomposition its input point lies in, as one-hot indicator outputs; piecewise definitions (a piecewise-linear activation, a case-defined dynamics) enter the hypernet through it. This rule discharges the case a proof is actually in: from a premise placing  $x$  *strictly inside* cell  $C_i$  — a conjunction of strict barycentric inequalities in the pinned flat vertex order — it concludes the full one-hot vector,  $b_i = 1$  and  $b_j = 0$  for every  $j \neq i$ . A producer reaches for it after region reasoning (the region introduction rules, SUBDIVIDE) has confined the input to one cell's interior, and needs the indicator values as arithmetic facts downstream — typically to substitute a branch's closed form for the primitive's output.

What the checker recomputes, given the payload (schema, cell index, cited application, premise proof): that the cited cell application is present in the hypernet with the input wire typed at shape `[ambDim]` and every output at total size one; that the premise formula is byte-for-byte the schema-derived strict-interior build for cell  $i$  (barycentric atoms recomputed from the vertex coordinates — no formula text trusted from the wire); and that the conclusion is the recomputed one-hot form. Soundness then rides the model: admissibility of the cell application forces some cell choice  $k$  with weak membership and the one-hot outputs at  $k$ ; the strict premise pins  $k = i$  through the schema's interior-disjointness well-formedness.

Each hypothesis is load-bearing. Weaken strictness to weak membership and a boundary point of two cells admits a valuation one-hotting the *other* cell — the conclusion fails. Drop interior-disjointness (distinct cells of the enumeration have disjoint interiors — which the complex's simplicial conformity does NOT imply: conformity never sees the extension masks and permits duplicate cell entries) and the model may one-hot an overlapping cell. Drop the output typing and the model's entry-level one-hot fact decouples from the whole-wire equality atoms (a zero-size output satisfies every atom vacuously; a multi-entry output can falsify the atom away from entry zero). Drop the input-shape tie and the premise's constraint on the input tensor no longer speaks about the model's evaluation point. The proof section walks these in order.

**notes** The checkable fragment is 1-dimensional (two-vertex cell supports on distinct coordinates) — the same fragment as the region machinery; everything beyond is refused, never approximated. The intended catalogue elaboration (case analysis over the cell axiom's disjunction) awaits the context-carrying case-analysis constructor; the shipped warrant is a direct semantic lemma, the degenerate-rewrite shape the PCONSTEXACT section defines.

```

**The recomputed forms and the payload.** The premise and conclusion formulas are never read off the certificate as text: the checker rebuilds both from the schema — the strict-interior conjunction from the 1-D barycentric coordinate terms (`baryLambdas1D`, offset-first affine normal forms over the two-vertex support), the conclusion from the one-hot pattern — and the payload's form fields assert equality with the rebuilt formulas. A skeptical reader should confirm by eye: the builds succeed only over a 1-dimensional complex with exactly two support vertices at distinct coordinates (everything else reads none and the rule refuses); the strict comparators are  $<$  at extended vertices and  $>$  at core vertices; and the payload carries the port-typing obligations (input at `[ambDim]`, outputs at total size one) explicitly.

**The semantic side: strict regions and interior disjointness.** MaskRegionStrict is the strict-sign twin of the weak region membership the model's cell fact carries; SimpC.CellIntDisjoint is the well-formedness the pinning argument consumes, stated over cell *indices* (so duplicate entries are excluded) at rational points (the model's cell inputs are rational). It is consumed as a conjunct of the cell application's model-level fact: an application over a non-disjoint enumeration admits no valuation — hypothesis-side vacuity, sound but weak — rather than an unsound conclusion. The predicate is a proposed schema amendment realized provisionally; the roster page records its status.

BernsteinLogic.Catalogue . MaskRegionStrict

definition bound

```

/-- Strict-interior membership: the same weights with STRICT signs on
every mask vertex (< 0 extended, > 0 core) – the region the
Cell-In-Interior premise certifies. -/
def MaskRegionStrict (C : SimpC) (mask ext : Fin C.nVertices → Bool)
  (x : Fin C.ambDim →  $\mathbb{Q}$ ) : Prop :=
   $\exists \text{ lam} : \text{Fin C.nVertices} \rightarrow \mathbb{R},$ 
  ( $\forall v, \text{mask } v = \text{false} \rightarrow \text{lam } v = 0$ )  $\wedge$ 
   $\text{finSum C.nVertices lam} = 1 \wedge$

  ( $\forall v, \text{mask } v = \text{true} \rightarrow \text{ext } v = \text{false} \rightarrow 0 < \text{lam } v$ )

```

BernsteinLogic.Catalogue . SimpC.CellIntDisjoint

definition bound

```

/-- PROPOSED-B2-DISJOINT (provisional): distinct cells of a schema's
enumeration have disjoint interiors – no rational point lies strictly
inside cell i and in the CLOSED region of a different cell k. This is
what the cell rules' admissibility derivation cites
("conformity: distinct cells have disjoint interiors"), and the
schema's `conformity` field does NOT deliver it: that field constrains
simplex-mask intersections only – it never sees the ( $\Delta, S$ ) extension
masks, and it permits literally duplicate cell entries, either of which
makes Cell-In-Interior UNSOUND (the model may one-hot a different
overlapping cell). Stated over INDICES so duplicates are excluded, at
 $\mathbb{Q}$  points because the model's Cell inputs are rational.  $\Sigma \pm$  satisfies it
(the two rays share only the origin, strictly inside neither).

```

Lives here (not as a `SimpC` field) because the quantification is over REAL weights – mathlib-side of the core/mathlib module split – and is consumed as a

conjunct of the Cell sp-fact below: a cell application over a non-disjoint schema admits NO valuation, the same "soundness errors are excluded from every value set" reading that rejects NaN executions (a hypothesis-side vacuity: sound, merely weak). -/

```

def SimpC.CellIntDisjoint (C : SimpC) : Prop :=
   $\forall i \text{ k} : \text{Fin C.cells.length}, i \neq k \rightarrow$ 
   $\forall x : \text{Fin C.ambDim} \rightarrow \mathbb{Q},$ 
  MaskRegionStrict C (C.cells.get i).1 (C.cells.get i).2 x  $\rightarrow$ 
   $\neg \text{MaskRegion C (C.cells.get k).1 (C.cells.get k).2 x}$ 

```

## Correspondence (Steele display $\leftrightarrow$ Lean)

**reviewer-certified against the displayed texts** The dictionary below is a reviewer-certified statement of how the mechanized statements above interpret the displayed rule: display metavariable  $\mapsto$  Lean binder, each display hypothesis  $\mapsto$  the premise or side condition carrying it, the display conclusion  $\mapsto$  the goal — with any deliberate difference in width between display and mechanization named outright. Certification is recorded as

a hash triple over (the displayed cell, the extracted statement texts, this dictionary's own text); if any of the three changes, this block turns amber until a reviewer re-certifies. The correspondence claim itself remains editorial — reviewer-grade, not machine-checked; its machine-checked successor types each soundness statement against the rule as a structured object, and supersedes this block per rule as it lands.

Judgment frame as in **AX**; sub-derivation premise as at **WEAKEN**.

- $\Sigma \mapsto \text{schema} : \text{SimpC}; i \mapsto \text{whichI} : \text{Fin } \text{schema.cells.length}; x \mapsto \text{the term } .\text{var } \text{input}$  — the region term literally is the input wire, as at **BERNCONE**;  $b_1, \dots, b_N \mapsto \text{outputs} : \text{List Wire}$ .
- the linkage  $\text{cell}[\Sigma]_{\{x\} \rightarrow \{b_1, \dots, b_N\}} \in H \mapsto \text{happ}$ , plain application-list membership — contrast the **LiRPA** family's size-gated lookup: here the port discipline rides two explicit typing hypotheses instead, **hinshape** (the input wire's type has shape  $[\text{schema.ambDim}]$ ) and **houtS** (every output wire singleton-sized). Neither has a displayed row; the payload carries both verbatim (**PCellInIntData**'s port-typing fields, displayed above); they are load-bearing twice: the model's sp-fact pins entry 0 of each output while the conclusion atom evaluates the whole wire, and the premise atoms constrain the input tensor, which ties to the model's rational point only at the declared shape. The same undisplayed typing pack as at **NORM**.
- premise  $\Phi \vdash \bigwedge_v \lambda_v^{C_i}(x) \bowtie_v^0 0 \mapsto \text{ih}$  with **hint** : **cellStrictInteriorForm** **schema** (.var **input**) **whichI** **premise.post** — the premise formula is pinned as the *build's* output: the two-atom conjunction in flat vertex order, comparators  $<$  on extended vertices and  $>$  on core ones exactly as displayed, each atom comparing the barycentric entry to .const 0. The build succeeds only at **schema.ambDim** = 1, so the certified reach of the displayed rule is the 1-dimensional fragment, by refusal (the **CONVELIM/CONVINTRO** class; the note above says it, this triple certifies it).  $\Phi$  shared via **hpre**.
- conclusion  $\Phi \vdash b_i = 1 \wedge \bigwedge_{j \neq i} b_j = 0 \mapsto \text{the goal under hpost} : \text{cellOneHotForm } \text{schema} \text{ outputs } \text{whichI } \text{seq.post}$  — pinned as the one-hot build's output: the  $b_i = 1$  atom first, then the ascending- $j$  chain of zeros; the displayed big-wedge has exactly one accepted spelling.
- nowhere in the certificate: the interior-disjointness well-formedness. It is consumed from the *model side* — admissible valuations carry **SimpC.CellIntDisjoint** in the cell sp-fact (certified alongside), and the proof pins the model's cell choice with it — so the display is right to show no such premise, and the rule's soundness is honestly conditional on that provisional schema conjunct (the commentary's **PROPOSED-B2-DISJOINT** story, visible in the statement chain).

Width note: within the 1-dimensional fragment, and modulo the undisplayed port-typing pack flagged above, nothing certified is narrower or wider than the display — every hypothesis is consumed, and the two builds pin both formulas to single spellings.

## Lean verifier receipts

module **BernsteinLogic.Soundness**; bound build **a20d90e66c13...** (bound from receipt **a9c0e34d3e3c9c8c**, 2026-08-03T21:30:36Z). A receipt records that named checking layers accepted a build: (module, compiled-artifact SHA-256, environment SHA-256, checker layers), minted when the checking gate ran; the store receipts attesting the bound build are listed with the layers each run credited. Nothing here asks the reader to trust the store: every layer is an independently runnable program over the quoted sources — rebuild the module and re-run the checkers to reproduce the verdict. Receipts attesting superseded builds credit no layer and are omitted from this rendering (the count of omissions, if any, is noted below).

## HOL verifier receipts

documentary hol-strict CLEAN: theory bern\_tr\_catdata2, 272 theorems, 0 cheat-tagged, 0 nonstandard axioms (whitelist: DISK\_THM; the four bool axioms) — verification run of 2026-07-22 on an isolated build host, against a content-addressed checkout of the exact sources cited here (git blob cd3c1e95...). The formerly dropped cell-payload island is ported: this rule's arm of the mutual wellformedness predicate states the application membership, the input-shape gate, the strict-interior premise and the one-hot conclusion (the form faces as boolean Build-equations, the characterization convention), and the form characterizations themselves are ported in theory bern\_tr\_catforms (cellStrictInteriorForm\_char / cellOneHotForm\_char, 23 theorems, 0 offences, same run). The receipt theorem cited above is the arm's kernel-evaluated accept/refusal pair; the shared barycentric ingredient (baryCoeffs1D) was already ported and receipted. Honest residue: the cell soundness argument (the Lean development's sound\_cellInInterior) is not yet ported; the payload/builder layer above is.

HOL receipts are documentary: quoted results of hol-strict runs and census rows from the HOL4 development's build evidence, not minted receipt artefacts. A HOL receipt store (the Lean store's twin) is named future work.

## Proof

Genre: admissible rule (tier 2) — a proof-tree-rewriting recipe. The intended elaboration is a case analysis over the cell primitive's one-hot disjunction (the  $\text{sp}[\text{cell}[\Sigma]]$  axiom — the calculus's only source of disjunction); the *realized* warrant is the degenerate rewrite in the  $\text{PCONSTEXACT}$  sense, discharging against a named verified semantic lemma. Both are presented, and the honest reason the first is not yet a checkable catalogue derivation is stated.

**Recipe R24.1** (the intended rewrite — case analysis over the cell disjunction). A cell application  $\text{cell}[\Sigma]_{\{x\} \rightarrow \{b_1, \dots, b_N\}}$  contributes to the ambient premise its one-hot disjunction

$$\text{sp}[\text{cell}[\Sigma]] = \bigvee_{k=1}^N \left( x \in \overline{C_k} \wedge b_k = 1 \wedge \bigwedge_{j \neq k} b_j = 0 \right).$$

The intended unpacking of one  $\text{CELL-IN-INTERIOR}$  node is a case split on  $k$ : in branch  $k = i$  the conclusion  $b_i = 1 \wedge \bigwedge_{j \neq i} b_j = 0$  is reached from the case hypothesis by conjunction plumbing ( $\wedge E$  and  $\wedge I$  under whatever association the axiom's serialization fixes); in a branch  $k \neq i$  the case hypothesis  $x \in \overline{C_k}$  contradicts the rule's strict-interior premise  $x \in \overset{\circ}{C}_i$  — *provided no point lies strictly inside one cell of the enumeration and weakly inside another*, which is exactly the schema well-formedness the soundness theorem consumes ([Remark R24.5](#)). Two honest gaps keep this a template rather than a shipped derivation: (i) the disjunction sits *inside* the premise conjunction, and the calculus's disjunction elimination as currently realized acts only on a disjunction at the root of the premise — the context-carrying form that reaches it is proven as a satellite theorem but its core constructor swap is still scheduled; (ii) the contradiction in the off-branches is semantic (disjoint interiors), not yet a formula-level refutation in the negation-free grammar.

**Recipe R24.2** (the realized rewrite — discharge against the semantic lemma). As shipped, the rule is admissible by *reduction to verified machinery* (the  $\text{PCONSTEXACT}$  pattern): the node

$$\frac{\mathcal{T} \triangleright \Phi \vdash \bigwedge_v \lambda_v^{C_i}(x) \bowtie_v^\circ 0}{\Phi \vdash b_i = 1 \wedge \bigwedge_{j \neq i} b_j = 0} \text{CELL-IN-INTERIOR} \rightsquigarrow \text{discharged by sound\_cellInInterior},$$

where the premise is the *strict* barycentric-interior conjunction for cell  $C_i$  (one strict atom per support vertex,  $<$  for extended vertices,  $>$  for core vertices, in the pinned flat vertex order) and the checker recomputes both formula shapes from the schema — the premise via  $\text{cellStrictInteriorBuild}$ , the one-hot conclusion via  $\text{cellOneHotBuild}$  — so no formula text is trusted from the certificate.

**Proposition R24.3** (semantic warrant). *Suppose the payload carries a proof of the strict-interior premise, the cited cell application is in the hypernet, the input wire is typed at shape  $[\text{ambDim}]$ , every output wire at total size 1, and the premise and conclusion formulas match the recomputed builds. Then the conclusion sequent is semantically valid.*

*Proof sketch (the lemma's actual route).* Fix an admissible valuation  $\sigma$  satisfying  $\Phi$ . Admissibility of the cited cell application yields the model-level fact: the schema's cells have disjoint interiors, the input wire holds a rational point  $x$ , and there is a cell choice  $k$  with  $x \in \mathcal{R}(\Delta_k, S_k)$  (weak membership) whose one-hot valuation the outputs realize — entry 0 of output  $j$  reads 1 if  $j = k$ , else 0. The premise, transported through the input wire's declared shape (the tensor-to-point tie), gives *strict* barycentric signs at  $x$  for cell  $i$ , i.e.  $x$  lies in the strict interior of  $C_i$  ( $\text{maskRegionStrict\_pair\_intro}$  assembles the region witness from the two strict atoms). If  $k \neq i$ , the interior-exclusion well-formedness is contradicted:  $x$  is strictly inside  $C_i$  and weakly inside  $C_k$ , the exact configuration [Remark R24.5](#)'s predicate forbids (strict-versus-weak exclusion — deliberately stronger than bare disjointness of open interiors, which a strictly-interior-to- $C_i$  point on  $C_k$ 's boundary would survive). So  $k = i$ , and the one-hot output pattern at  $k$  is the conclusion: each conjunct is an equality between a singleton-shaped output wire and the constant its entry holds ( $\text{holds\_cellOneHot}$ ).  $\square$

*Remark R24.4* (why the premise must be strict). At a shared boundary face the one-hot semantics deliberately admits *either* adjacent cell as the model's choice: a boundary point has the one-hot set of every cell whose closure contains it. A weak-interior premise therefore cannot pin  $k$  — for  $x$  on the face between  $C_i$  and  $C_k$  the valuation one-hotting  $C_k$  satisfies the weak premise and falsifies  $b_i = 1$ . Strictness excludes exactly the boundary, where the pinning genuinely fails; the companion rule  $\text{CELL-OUT}$  covers boundary points from the other side.

*Remark R24.5* (the disjointness hypothesis, and why the complex's conformity does not deliver it). The step  $k = i$  uses: no rational point lies strictly inside cell  $i$  and weakly inside a *different* cell  $k$  ( $\text{SimpC.CellIntDisjoint}$ , stated over cell *indices* so duplicate entries are excluded). The schema's simplicial conformity field does not imply this: conformity constrains simplex-mask intersections only, never sees the extension masks that carve cells out of simplices, and permits literally duplicate cell entries — either defect, were the predicate not consumed, would let the model one-hot an overlapping cell and falsify the conclusion. The predicate is consumed as a conjunct of the cell application's model-level fact: an application over a non-disjoint enumeration admits no valuation at all (hypothesis-side vacuity — sound, merely weak), the same reading that excludes NaN executions. It is a schema amendment adopted provisionally, pending ratification.

*Remark* R24.6 (the port-typing hypotheses are load-bearing twice). The model’s one-hot fact pins *entry* 0 of each output wire, while the conclusion’s equality atoms evaluate the *whole* wire; the total-size-1 typing is what makes the two coincide (a multi-entry output could satisfy the entry fact while its remaining entries falsify the atom; a zero-size output would satisfy every atom vacuously). Dually, the premise’s barycentric atoms constrain the input *tensor*, and the declared shape [ambDim] (with ambDim = 1 in the checkable fragment) ties that tensor to the model’s rational point.

*Remark* R24.7 (scope of the checkable fragment). `cellStrictInteriorBuild` succeeds only over a 1-dimensional complex with a two-vertex cell support on distinct coordinates — the same fragment as the region machinery elsewhere in the catalogue; everything beyond it is refused, not approximated (fail-toward-refusal). Higher-dimensional cell complexes await their own barycentric builders; the rule’s statement is dimension-general and only the builder gates narrow it.

## Rule 25. CELL-OUT (admissible rule)

### The rule (Steele metanotation)

as realized in the mechanized development; source row: `rules.toml` — *Cell-Out*. The metanotation statement is typeset by hand for notational quality; its mechanized ground truth is the Lean statement below, extracted from the sources at every build of this book and hash-bound. The rule *roster* is machine-checked (every mechanized rule tag round-trips to exactly one catalogue row); the statement *text* is editorial, checked by eye against the extracted Lean beside it.

$$\frac{\Phi \vdash \lambda_w^{C_j}(x) \bowtie^\circ 0 \text{ (a single strict separating atom at a named witness vertex } w \text{ of } C_j; > \text{ for extended } w, < \text{ for core } w) \quad \text{cell}[\Sigma]_{\{x\} \rightarrow \{b_1, \dots, b_N\}} \in H}{\Phi \vdash b_j = 0} \quad \text{CELL-OUT}$$

applies even at boundary points.

CELL-OUT is CELL-IN-INTERIOR's refutation companion: from a premise strictly separating the input point from cell  $C_j$ , it zeroes that cell's indicator —  $\Phi \vdash b_j = 0$  — and it does so *even at boundary points of other cells*, where the pinning rule cannot fire. The paper states the premise as  $x \notin \overline{C_j}$ , a disjunction of strict halfspace violations; the negation-free formula grammar has no rendering of that, so the realized rule serializes a witness instead: a single strict barycentric atom at a *named witness vertex*  $w$  of  $C_j$ , with the polarity that contradicts membership ( $>$  at an extended vertex,  $<$  at a core vertex). One atom replaces the disjunction — no loss for producers, who know which halfspace their point violates, and a strict gain for the checker, which does no disjunctive reasoning. A producer uses the rule to kill off-branches of a piecewise definition: once every indicator but one is zero, downstream arithmetic (a weighted combination over branches, a substitution) simplifies to the live branch.

What the checker recomputes: presence of the cited cell application with the same port typing as the companion rule (input at [ambDim], outputs at total size one); that the witness vertex lies in cell  $j$ 's support mask (the build refuses otherwise); that the premise is byte-for-byte the recomputed separating atom for  $(j, w)$ ; and that the conclusion is the recomputed  $b_j = 0$  atom.

Each hypothesis is load-bearing. The support-mask guard: an atom at a vertex outside  $C_j$ 's support constrains a weight the membership predicate never mentions — no contradiction, no soundness. Strictness of the atom: the model's membership fact delivers weak signs, and only a strict opposite sign contradicts them (a weak atom is compatible with a boundary weight of zero, where the model may still choose cell  $j$ ). The port typing: same double duty as in the companion rule — the tensor-to-point tie on the input, and the entry-to-whole-wire lift on the output. Notably ABSENT here: the interior-disjointness well-formedness — the refutation is by weight uniqueness on the two-vertex support against the strict witness atom, within cell  $j$  alone, so this rule stands even where only the companion needs the provisional schema amendment. The proof section walks these in order.

### Lean statement

BernsteinLogic.Soundness . **sound\_cellOut**

statement bound

```

**The recomputed forms and the payload.** As for the companion rule, no formula text is trusted from the certificate: the witness atom is rebuilt from the schema's barycentric data at the named vertex (note the guard — the build refuses a witness vertex outside the cell's support mask), the conclusion atom from the output list, and the payload's form fields assert equality with the rebuilt formulas. The same two-vertex 1-D fragment gates apply (`baryLambdas1D`, displayed in the `CELL-IN-INTERIOR` section); everything beyond the fragment is refused.

## Correspondence (Steele display ↔ Lean)

**reviewer-certified against the displayed texts** The dictionary below is a reviewer-certified statement of how the mechanized statements above interpret the displayed rule: display metavariable  $\mapsto$  Lean binder, each display hypothesis  $\mapsto$  the premise or side condition carrying it, the display conclusion  $\mapsto$  the goal — with any deliberate difference in width between display and mechanization named outright. Certification is recorded as a hash triple over (the displayed cell, the extracted statement texts, this dictionary's own text); if any of the three changes, this block turns amber until a reviewer re-certifies. The correspondence claim itself remains editorial — reviewer-grade, not machine-checked; its machine-checked successor types each soundness statement against the rule as a structured object, and supersedes this block per rule as it lands.

Judgment frame as in Ax; sub-derivation premise as at WEAKEN; binders, linkage row, and the undisplayed port-typing pack (happ, hinshape, hout, — payload fields PCellOutData) exactly as in the CELL-IN-INTERIOR dictionary, with  $j \mapsto$  whichJ and the witness vertex  $w \mapsto$  ww : Fin schema.nVertices.

- premise  $\Phi \vdash \lambda_w^{C_j}(x) \bowtie^\circ 0 \mapsto$  ih with hwit : cellOutWitnessForm schema (.var input) whichJ ww premise.post — pinned as the witness build's output: a single strict atom at the flat-order entry of the named vertex, comparator  $>$  on an extended witness and  $<$  on a core one, exactly the display's polarity (note the deliberate flip against CELL-IN-INTERIOR's interior comparators); the build's guard demands the witness vertex lie in  $C_j$ 's support — the display's “of  $C_j$ ” — and, as at the companion, succeeds only at schema.ambDim = 1: the certified reach is the 1-dimensional fragment, by refusal.  $\Phi$  shared via hpre.
- conclusion  $\Phi \vdash b_j = 0 \mapsto$  the goal under hpost : cellOutZeroForm schema outputs whichJ seq.post — the single equality atom, indicator wire left, .const 0 right.
- the disjointness conjunct of the model's sp-fact is *discarded* by this rule's proof (the statement chain consumes the one-hot fact only) — certifying the commentary's claim that CELL-OUT stands independent of the provisional schema amendment its companion needs.

Width note: “applies even at boundary points” is carried structurally — the witness atom is strict and nothing demands interiority of  $x$ ; within the 1-dimensional fragment, and modulo the undisplayed port-typing pack inherited from the companion dictionary, neither side is wider, every hypothesis consumed.

## Lean verifier receipts

module BernsteinLogic.Soundness; bound build a20d90e66c13... (bound from receipt a9c0e34d3e3c9c8c, 2026-08-03T21:30:36Z). A receipt records that named checking layers accepted a build: (module, compiled-artifact SHA-256, environment SHA-256, checker layers), minted when the checking gate ran; the store receipts attesting the bound build are listed with the layers each run credited. Nothing here asks the reader to trust the store: every layer is an independently runnable program over the quoted sources — rebuild the module and re-run the checkers to reproduce the verdict. Receipts attesting superseded builds credit no layer and are omitted from this rendering (the count of omissions, if any, is noted below).

| receipt          | minted               | layers             | status  |

## HOL verifier receipts

**documentary** hol-strict CLEAN: theory bern\_tr\_catdata2, 272 theorems, 0 cheat-tagged, 0 nonstandard axioms (whitelist: DISK\_THM; the four bool axioms) — verification run of 2026-07-22 on an isolated build host, against a content-addressed checkout of the exact sources cited here (git blob cd3c1e95...). The formerly dropped cell-builder island is ported: the witness build/form pair displayed here verbatim (the Form face as a boolean Build-equation, the characterization convention), with kernel-evaluated receipts (cellOutWitnessBuild\_receipt / cellOutWitnessFormB\_receipt), the payload arm of the mutual wellformedness predicate with its own accept/refusal receipt (cited above), the zero-build twin in theory bern\_tr\_checkfn (cellOutZeroBuild, 8 theorems, 0 offences, same run), and its form characterization in theory bern\_tr\_catforms (cellOutZeroForm\_char, 23 theorems, 0 offences). The shared barycentric ingredient (baryCoeffs1D) was already ported and receipted. Honest residue: the cell soundness argument (the Lean development's sound\_cellOut) is not yet ported; the payload/builder layer above is.

HOL receipts are documentary: quoted results of hol-strict runs and census rows from the HOL4 development's build evidence, not minted receipt artefacts. A HOL receipt store (the Lean store's twin) is named future work.

## Proof

Genre: admissible rule (tier 2) — a proof-tree-rewriting recipe. Same family as CELL-IN-INTERIOR: the intended elaboration is a case analysis over the cell primitive's one-hot disjunction; the realized warrant is the degenerate rewrite discharging against a verified semantic lemma, for the same two reasons stated in that rule's first recipe (the context-carrying case analysis is not yet a core constructor, and the off-branch contradiction is semantic). Only the branch-closing argument differs — and it is *lighter*: no disjointness hypothesis is consumed.

**Recipe R25.1** (the CELL-OUT instance — the realized rewrite).

$$\frac{\mathcal{T} \triangleright \Phi \vdash \lambda_w^{C_j}(x) \bowtie^\circ 0}{\Phi \vdash b_j = 0} \text{ CELL-OUT} \quad \rightsquigarrow \quad \text{discharged by sound\_cellOut,}$$

where the premise is a *single strict separating atom* at a named witness vertex  $w$  of cell  $C_j$  ( $>$  if  $w$  is an extended vertex,  $<$  if a core vertex — the sign that contradicts membership), and the checker recomputes premise and conclusion shapes from the schema (cellOutWitnessBuild, cellOutZeroBuild). The payload names  $w$  explicitly; the build refuses any  $w$  outside  $C_j$ 's support mask.

**Proposition R25.2** (semantic warrant). *Under the payload hypotheses (premise proof; cited cell application in the hypernet; input typed at shape [ambDim]; outputs at total size 1; premise and conclusion matching the recomputed builds), the conclusion sequent is semantically valid.*

*Proof sketch (the lemma's actual route).* Fix an admissible valuation  $\sigma$  satisfying  $\Phi$ . The cell application's model-level fact yields the rational input point  $x$ , a cell choice  $k$  with  $x \in \mathcal{R}(\Delta_k, S_k)$ , and the one-hot output valuation at  $k$ . Suppose  $k = j$ . On the two-vertex support the barycentric weights of  $x$  are *unique* — they are determined affinely by the point — so weak membership in cell  $j$  pins their signs:  $\leq 0$  at extended vertices,  $\geq 0$  at core vertices (the pair-elimination lemma). The premise delivers the *strict opposite* sign for the weight at the witness vertex  $w$  (transported to the model's point through the input wire's declared shape), a direct contradiction. Hence  $k \neq j$ , and the one-hot fact reads entry 0 of output  $j$  as 0; the total-size-1 typing lifts that entry to the whole-wire equality  $b_j = 0$ .  $\square$

**Remark R25.3** (why a witness vertex replaces the paper's set complement). The source statement's premise is  $x \notin \overline{C_j}$  — a *disjunction* of strict halfspace violations, one per bounding halfspace. The formula grammar is negation-free and the premise of a rule application must be a formula the calculus can derive, so the amendment serializes a choice of disjunct instead: *which* halfspace is strictly violated, named by *which* vertex carries the violated barycentric sign. One atom replaces the disjunction with no loss for producers — within the fragment the builders admit, where the cell's closure is exactly the conjunction of its per-vertex sign constraints, a point outside the closure violates at least one of them, and the producer knows which — and a strict gain for the checker (no disjunctive reasoning at check time).

**Remark R25.4** (the witness must be a support vertex of  $C_j$ ). The build guards  $w \in \text{supp}(C_j)$ . Without the guard the premise atom would constrain a barycentric coordinate that cell  $j$ 's membership predicate never mentions — the sign contradiction in Proposition R25.2 needs the weight at  $w$  to be one of the two the membership fact actually constrains. (On the two-vertex support this is also what makes the atom well-defined: the builder computes  $\lambda_w^{C_j}$  from the support pair's coordinates.)

**Remark R25.5** (boundary points, and the division of labor with CELL-IN-INTERIOR). The rule applies even at boundary points of *other* cells: the contradiction is between a strict violated sign and weak membership of the *same* cell  $j$ , so no interior-disjointness hypothesis is consumed — a point on the shared face of  $C_i$  and  $C_k$  can still be strictly separated from a third cell  $C_j$ , and the rule concludes  $b_j = 0$  regardless of which of the two adjacent cells the model one-hots. This is the refutation companion of

CELL-IN-INTERIOR, whose pinning argument fails precisely on boundaries and needs disjointness; between them, interior points get the full one-hot vector, and a boundary point gets  $b_j = 0$  for every cell  $j$  whose closure excludes it — the cells actually sharing the face stay unpinned, necessarily: the model may one-hot either, so no sound rule could zero theirs.

*Remark* R25.6 (scope of the checkable fragment). As for CELL-IN-INTERIOR: the builders succeed over 1-dimensional complexes with two-vertex cell supports on distinct coordinates, and refuse everything else. The statement is dimension-general; only the builder gates narrow it.

## Rule 26. PConstExact (admissible rule)

### The rule (Steele metanotation)

as realized in the mechanized development; source row: `rules.toml` — *PConstExact*. The metanotation statement is typeset by hand for notational quality; its mechanized ground truth is the Lean statement below, extracted from the sources at every build of this book and hash-bound. The rule *roster* is machine-checked (every mechanized rule tag round-trips to exactly one catalogue row); the statement *text* is editorial, checked by eye against the extracted Lean beside it.

$$\frac{e_1, e_2 \text{ wire-free (closed) terms} \quad \bowtie \in \{<, \leq, =, \geq, >\} \quad e_1 \bowtie e_2 \text{ holds under exact evaluation in } \mathbb{Q}}{\Phi \vdash e_1 \bowtie e_2} \text{PConstExact}$$

the third premise is decided, not assumed: both terms are closed, so the comparison evaluates in exact rational arithmetic (the checker's realization is the verified closed evaluator, which returns no verdict on any term containing a wire — closedness is thereby implied, never a trusted annotation).

PConstExact is the calculus's ground-fact rule: it lets a derivation state an exact closed arithmetic fact  $\vdash -3/4 \leq 0$ , or  $\vdash (2/3)^2 = 4/9$  — with no premises. Before it, ground facts were nearly out of reach: NORM, premise-free, already states closed equalities of identical canonical forms ( $\vdash (2/3)^2 = 4/9$  falls to it), but no rule stated a ground *order* comparison  $\vdash -3/4 \leq 0$  had no derivation. A producer uses it wherever a numeric side condition enters a derivation — a constant bound, an exact constant comparison feeding a later combination step.

What the checker recomputes is the entire side condition: `evalClosed`, the verified closed-term evaluator, exact over  $\mathbb{Q}$ , must return `true` on the comparison. There is no separate “closedness” hypothesis to check: the evaluator returns `none` the moment it meets a wire, so a `true` result certifies closedness as a byproduct — a hypothesis the payload cannot mis-declare. One comparator,  $\neq$ , is excluded from the admissible set even though the underlying semantic lemma covers it: the calculus maintains a second, three-valued soundness screen, and a premise-free  $\neq$  atom would break it (the proof section unpacks why). Without the exclusion, the rule would silently invalidate an invariant the rest of the calculus is entitled to assume.

**notes** The rule generalizes the earlier scalar-constant-fact rule, retained as the corner case  $e_2 = 0$ . Its tier is the taxonomy's recorded boundary case: admissible by *reduction to verified machinery* — the soundness lemma is one step to the evaluator-correctness theorem — rather than by unpacking into a catalogue derivation, because for its order conclusions no such derivation exists; that impossibility is the rule's point. It is not core because it adds no new kernel semantic content.

### Lean statement

## Correspondence (Steele display ↔ Lean)

**reviewer-certified against the displayed texts** The dictionary below is a reviewer-certified statement of how the mechanized statements above interpret the displayed rule: display metavariable  $\mapsto$  Lean binder, each display hypothesis  $\mapsto$  the premise or side condition carrying it, the display conclusion  $\mapsto$  the goal — with any deliberate difference in width between display and mechanization named outright. Certification is recorded as a hash triple over (the displayed cell, the extracted statement texts, this dictionary's own text); if any of the three changes, this block turns amber until a reviewer re-certifies. The correspondence claim itself remains editorial — reviewer-grade, not machine-checked; its machine-checked successor types each soundness statement against the rule as a structured object, and supersedes this block per rule as it lands.

- $e_1, e_2 \mapsto e_1 \bowtie e_2 : \text{Term}$ ;  $\bowtie \mapsto b : \text{BowTie}$ ; the judgment context  $\Phi$  and the concluded sequent  $\mapsto \text{seq} : \text{Sequent}$  with the conclusion tie  $\text{hpost} : \text{seq.post} = \text{atom } b \ e_1 \ e_2$ . Premise-freeness is represented by silence: no hypothesis mentions  $\text{seq.pre}$ , so the statement holds under arbitrary premises.
- the displayed premise ( $e_1 \bowtie e_2$  holds under exact evaluation in  $\mathbb{Q}$ )  $\mapsto \text{hEval} : (\text{Formula.atom } b \ e_1 \ e_2).\text{evalClosed} = \text{some true}$  — note the some: the verified evaluator is partial and returns none on any wire, so the display's separate “wire-free (closed) terms” hypothesis is *absorbed*: it has no Lean binder of its own because a successful evaluation certifies it.
- conclusion  $\Phi \vdash e_1 \bowtie e_2 \mapsto$  the goal  $\text{seq.semanticallyValid } H$ , validity at every valuation of the ambient hypernet.

Width note, deliberate and load-bearing: the display restricts  $\bowtie \in \{<, \leq, =, \geq, >\}$ , while the Lean statement is proven for *all* constructors of `BowTie`, including  $\neq$ . The comparator exclusion is an admission-layer fact — the checker refuses a premise-free  $\neq$  atom to protect the three-valued screen, as the commentary explains — not a semantic one. The mechanized statement is therefore strictly wider than the displayed rule, and the displayed rule is exactly the admitted fragment of it.

## Lean verifier receipts

module BernsteinLogic.Soundness; bound build a20d90e66c13... (bound from receipt a9c0e34d3e3c9c8c, 2026-08-03T21:30:36Z). A receipt records that named checking layers accepted a build: (module, compiled-artifact SHA-256, environment SHA-256, checker layers), minted when the checking gate ran; the store receipts attesting the bound build are listed with the layers each run credited. Nothing here asks the reader to trust the store: every layer is an independently runnable program over the quoted sources — rebuild the module and re-run the checkers to reproduce the verdict. Receipts attesting superseded builds credit no layer and are omitted from this rendering (the count of omissions, if any, is noted below).

## HOL verifier receipts

**documentary** hol-strict CLEAN: theory bern\_tr\_catdata, 252 theorems, 0 cheat-tagged, 0 nonstandard axioms (whitelist: DISK\_THM; the four bool axioms) — verification run of 2026-07-22 on an isolated build host, against a content-addressed checkout of the exact sources cited here (git blob f8fceac5...). The closed-comparison payload predicate displayed above is the rule's entire checkable content — comparator confined to the admissible five, both terms evaluated by the closed exact- $\mathbb{Q}$  evaluator, conclusion pinned to the payload — with a kernel-evaluated accept/refusal receipt. The proof-object stratum consumes it verbatim as this rule's arm of the mutual wellformedness predicate (theory bern\_tr\_catdata2, 272 theorems, 0 offences, same run), and the rule-tag roster carries the rule. As on the Lean side, the rule rides the proof-object family, not the first-order wire format: the wire tag remains deferred on both sides (the emit path refuses until allocated), so there is deliberately no column-side check to mirror. Honest residue: the semantic reduction (the Lean development's sound\_pConstExact, one step to the verified closed evaluator) is not yet ported.

HOL receipts are documentary: quoted results of hol-strict runs and census rows from the HOL4 development's build evidence, not minted receipt artefacts. A HOL receipt store (the Lean store's twin) is named future work.

## Proof

Genre: admissible rule (tier 2) — a proof-tree-rewriting recipe. The tier taxonomy defines tier 2 as *verified unpacking into core rules* (one node  $\rightarrow$  many); this rule is the taxonomy's recorded boundary case — admissible by *reduction to verified machinery*. The general template, both species included, is stated in the NORM section; the recipe below typesets the honest degenerate instance.

**Recipe R26.1** (the PConstExact instance — the degenerate rewrite). PConstExact has *no proof premises* ( $n = 0$ ), and its rewrite target contains *zero catalogue nodes*: no catalogue derivation states a ground *order* comparison — closed equalities of identical canonical forms fall to NORM already, but  $\vdash -3/4 \leq 0$  had no derivation before this rule — which is the rule's entire point. The rewrite therefore discharges the node against a named *verified theorem* rather than against catalogue structure:

$$\frac{e_1 \bowtie e_2 \text{ holds under exact evaluation in } \mathbb{Q}}{\Phi \vdash e_1 \bowtie e_2} \text{PConstExact} \rightsquigarrow \text{the checker replays evalClosed; holds\_of\_evalClosed\_true stands as warrant.}$$

The side condition is *computational* (exact  $\mathbb{Q}$  evaluation of a closed comparison — decidable, replayed by the checker), and the warrant theorem is kernel-verified once, globally: soundness of the rule is literally “the exact evaluator is correct.”

**Proposition R26.2** (semantic warrant). *If  $(\text{atom} \bowtie e_1 e_2).\text{evalClosed} = \text{some true}$  and the sequent's conclusion is that atom, the sequent is semantically valid over any hypernet, with arbitrary premise  $\Phi$ .*

*Proof.* Fix any valuation  $\sigma$  (admissibility and  $\sigma \models \Phi$  are not consulted — the rule is premise-free, the NORM convention). By the verified evaluator theorem `Formula.holds_of_evalClosed_true`, a formula whose closed evaluation returns true holds at *every* valuation: a closed term's evaluation consults no wire, so  $\sigma$  is never read, and the comparison was decided by exact arithmetic over  $\mathbb{Q}$ . That is the whole proof — `sound_pConstExact` is one exact step.  $\square$

**Remark R26.3** (closedness is implied, not declared). There is no “ $e_1, e_2$  closed” payload field to check: `evalClosed` returns none on any wire occurrence, so *some true* certifies closedness as a byproduct. A well-formedness hypothesis that the evaluator itself enforces is one the payload cannot mis-declare — unrepresentable, not discouraged.

**Remark R26.4** (why  $\neq$  is excluded — the  $M_3$  countermodel). The comparator set is confined to  $\{<, \leq, =, \geq, >\}$ : five of the six. The semantic lemma covers all six, but the calculus also maintains a three-valued screen (`ProofObject.m3sound`), whose disequality clause reads designated free-wire membership — so a wire-free  $\neq$  atom, its wire list empty, interprets to  $\perp$  under the  $M_3$  countermodel. Admitting  $\neq$  against arbitrary  $\Phi$  would then let a premise-free rule conclude screen value  $\perp$  under a premise valued  $\top$  ( $\vdash 1 \neq 2$  is true over  $\mathbb{Q}$ , and breaks the screen's premise- $\leq$ -conclusion invariant), breaking `m3sound`. The `notNE` payload field is shared with `ARITHATOM`, where the same gate carries different weight: both of that rule's spellings mention the same wires, so its screen value is preserved and the gate serves alignment (that section's closing remark); here the breakage is real. A hypothesis whose necessity comes not from  $\mathbb{Q}$ -semantics but from a *second* soundness invariant is exactly the kind a recipe must state, or the next porter re-learns it the hard way.

**Remark R26.5** (the subsumed corner, and coverage). `PRATFACT` (the scalar constant fact  $c \bowtie 0$ ) is the corner  $e_2 = 0$  of this rule and was subsumed when the roster was consolidated. Coverage today: the Term grammar makes every closed term rank-0, so the rule states every closed *scalar* exact comparison; the matrix corner (exact closed matrix identities, MIX's use case) needs closed-tensor constructors and a `QTENSOR`-valued closed evaluator — the named next leg, deliberately not hand-faked here.

## Rule 27. PBOUND (alias for SYZGY)

### The rule (Steele metanotation)

as realized in the mechanized development; source row: `rules.toml` — *PBound*. The metanotation statement is typeset by hand for notational quality; its mechanized ground truth is the Lean statement below, extracted from the sources at every build of this book and hash-bound. The rule *roster* is machine-checked (every mechanized rule tag round-trips to exactly one catalogue row); the statement *text* is editorial, checked by eye against the extracted Lean beside it.

$$\frac{\begin{array}{l} \{\Phi_i \vdash e_i \leq 0\}_{i=1}^n, \quad \Phi \supseteq \Phi_i \text{ conjunct-wise (checked)} \quad \{g_k = 0\}_k \text{ equality sub-conjuncts of } \Phi \quad \lambda_i \in \mathbb{Q}_{\geq 0} \\ \nu_k \in \mathbb{Q} \quad c \equiv \sum_i \lambda_i e_i + \sum_k \nu_k g_k \text{ (exact canonical polynomial)} \quad \text{bshape}_H(c) \neq \perp, \quad \text{wires}(c) \text{ all finitely typed in } H \\ \text{wires}(\Phi) \cup \text{wires}(c) \cup \bigcup_i \text{wires}(e_i) \text{ all typed at positive-size shapes in } H \\ \Psi \in \{c \leq 0, \quad e \geq 0 \text{ where } c = -e, \quad l \leq r \text{ where } c = l - r\} \end{array}}{\Phi \vdash \Psi} \quad \text{PBOUND}$$

PBOUND is the workhorse bound-node: a compact spelling of a SYZGY application whose entries the register prices as affine, with the conclusion exposed through the three-way reading selector — the raw zero-form  $c \leq 0$ , the sign-flipped  $e \geq 0$  where  $c = -e$ , or the literal atom  $l \leq r$  where  $c = l - r$ . It is the taxonomy's canonical alias: the payload is SYZGY's field-for-field, the unpack is the identity transport, and the wire format prices the affine register compactly. A producer emits it constantly: it is how an affine consequence of proven bounds becomes a first-class node whose conclusion can feed the rules that demand a particular atom shape — the  $\geq$ -reading makes a nonnegativity premise reachable from bound facts without a detour, and the literal-atom reading feeds interval-shaped consumers with no separate re-arrangement step.

What the checker recomputes is exactly SYZGY's obligation set — entry decoding against the pinned combination encoding, nonnegative weights, entry-sourcing from component conclusions and premise equality sub-conjuncts (both polarities on equalities), and the exact canonical-polynomial fold identity — plus the same bookkeeping (conjunct-wise premise containment, conclusion shape and finiteness, positive-size wires on premise, conclusion, and component conclusions). That section's commentary on what breaks without each hypothesis applies verbatim here, through the identity transport.

The affine restriction is the rule's published register (the roster note's pricing vocabulary — wire-format compactness for coefficient rows); it appears in neither the displayed premises nor the statement, and it is not a checked side condition: the replay is degree-blind and soundness never consults linearity. The three readings are one exact  $\mathbb{Q}$  identity re-presented under a sign flip; their semantic transport is proven once, in the target rule's section, and inherited here as a pure re-spelling.

**notes** The wire tag for this rule is deferred to a payload-window allocation; the emit path refuses the rule until the tag is allocated. The compact-register pricing is the reason the alias exists as a distinct spelling at all — semantically it adds nothing to its target, which is the alias genre working as intended.

### Lean statement

BernsteinLogic.Soundness . holds\_of\_syzygyConclusionForm

statement bound

```
-- The ge-bridge ring lemma (the both-polarity core change): every
reading admitted by
`syzygyConclusionForm conclusion` holds whenever the zero-normal atom
`conclusion ≤ 0` holds — the readings are the same exact  $\mathbb{Q}$  identity
re-presented under a sign flip. The zero-form is the identity transport,
the ge-polarity flip is ` $-e \leq 0 \rightarrow e \geq 0$ ', and the literal atom is
` $l - r \leq 0 \rightarrow l \leq r$ ` (ArithAtom's tensor-general sub-zero bridge).
Applied once inside `sound_syzygy`, so PSyzygy (tier-1), PBound's
compact spelling (tier-3), and any future  $\leq 0$ -shaped fact rule inherit
all readings with no separate polarity justification. -/
theorem holds_of_syzygyConclusionForm {H : Hypernet} {σ : H.Valuation}
  {conclusion : Term} {F : Formula}
  (hle : Formula.holds σ (.atom .le conclusion (.const 0)))
  (hform : syzygyConclusionForm conclusion F) :
  Formula.holds σ F
```

BernsteinLogic.Soundness . sound\_syzygy

statement bound

```
-- Soundness of Syzygy (= Lemma B, dialect D): valid components give a
valid composite. The argument is `sound_farkas`'s, with the per-entry
source discharge generalized: a component-sourced entry's atom holds by
component validity (through `premiseContains`), a wiring-sourced entry's
```

```

atom holds as a premise sub-conjunct; either way
`atomLeZeroPolys_sound_entryC` delivers per-entry nonpositivity at every
clamped per-entry valuation, and the nonnegative fold closes. The
zero-normal bound then reaches `seq.post` through whichever
`szygyConclusionForm` reading the payload declared (both-polarity core
change, 2026-07-18). -/
theorem sound_szygy {H : Hypernet} (st : SzygyStep H)
  (hcomps : ∀ c ∈ st.components, c.semanticallyValid H) :
  st.seq.semanticallyValid H

```

#### BernsteinLogic.Soundness . sound\_pBound

statement bound

```

/-- PBound soundness: INHERITED from `sound_szygy`, literally – the payload's
fields are `PSzygyData`'s verbatim (tier-3 compact spelling, 1 node → 1 node),
so the proof is the same `SzygyStep` handed to the same theorem. Polarity is
not justified here: since the both-polarity core change,
`sound_szygy` itself carries every
`szygyConclusionForm` reading through `holds_of_szygyConclusionForm`, and
PBound inherits them as a pure re-spelling. -/
theorem sound_pBound {H : Hypernet} {seq : Sequent} {components : List Sequent}

## Correspondence (Steele display ↔ Lean)

**reviewer-certified against the displayed texts** The dictionary below is a reviewer-certified statement of how the mechanized statements above interpret the displayed rule: display metavariable  $\mapsto$  Lean binder, each display hypothesis  $\mapsto$  the premise or side condition carrying it, the display conclusion  $\mapsto$  the goal — with any deliberate difference in width between display and mechanization named outright. Certification is recorded as a hash triple over (the displayed cell, the extracted statement texts, this dictionary's own text); if any of the three changes, this block turns amber until a reviewer re-certifies. The correspondence claim itself remains editorial — reviewer-grade, not machine-checked; its machine-checked successor types each soundness statement against the rule as a structured object, and supersedes this block per rule as it lands.

Verbatim the SYZGY dictionary, unbundled: where SYZGY's statement packs its obligations into a SyzgyStep, sound\_pBound takes the same eleven fields as flat binders — hpreC, hshape, hfin, hwpos, hcompPos, hvalid, hform, over the same components/combination/conclusion data with hcomps the component validities — and its entire proof is one application of sound\_syzgy to the repacked Step, visible in the displayed statement. The alias relation is thereby itself certified:  $1 \rightarrow 1$  at statement level, and (since the both-polarity core change)  $1 \rightarrow 1$  at reading level too — the displayed  $\Psi$  selector is the same syzgyConclusionForm the target consumes. This cell displays the evaluability and positive-size rows inline; their mapping is the SYZGY dictionary's, unchanged. No hypothesis differs, none is unused, and neither side is wider — the affine restriction the roster note mentions is wire-format compactness, absent from both the display's premises and the statement.

## Lean verifier receipts

module BernsteinLogic.Soundness; bound build a20d90e66c13... (bound from receipt a9c0e34d3e3c9c8c, 2026-08-03T21:30:36Z). A receipt records that named checking layers accepted a build: (module, compiled-artifact SHA-256, environment SHA-256, checker layers), minted when the checking gate ran; the store receipts attesting the bound build are listed with the layers each run credited. Nothing here asks the reader to trust the store: every layer is an independently runnable program over the quoted sources — rebuild the module and re-run the checkers to reproduce the verdict. Receipts attesting superseded builds credit no layer and are omitted from this rendering (the count of omissions, if any, is noted below).

| receipt          | minted               | layers             | status  |
|------------------|----------------------|--------------------|---------|
| a9c0e34d3e3c9c8c | 2026-08-03T21:30:36Z | build+decorrelated | current |

21 further receipt(s) in the store attest superseded builds of this module and are omitted from this rendering.

### Definition syzgyCheck\_def

```

Definition syzgyCheck_def:
  syzgyCheck cc components premise conclusion  $\Leftarrow$ 
    syzgyCheckCore cc components premise conclusion v
    syzgyCheckW cc components premise conclusion
End

```

## HOL verifier receipts

**documentary** hol-strict CLEAN over the ported checker chain: theory bern\_catalogue, 472 theorems, 0 cheat-tagged, 0 nonstandard axioms (whitelist: DISK\_THM; the four bool axioms) — verification run of 2026-07-22 on an isolated build host, scripts sha-matched verbatim to the sources cited here (git blob e41b9ed0...). Scope, stated honestly: the alias's entire combination check is the target rule's, so the ported syzygyCheck (with its accept and two reject receipt rows, quoted in the target rule's section) covers this rule's computational content; the conclusion-form reading selector and the payload layer ride the dependently-typed proof-object surface, which is a separately tracked porting stage. As on the FARKAS page: the Lean check has since grown a third (mixed tagged-union) branch, added 2026-07-19 after this port run — the divergence is refusal-direction only, and its port is named residue. Semantic stratum, also ported: the soundness twin sound\_pBound (theory bern\_tr\_soundsyz: hol-strict clean, 7 theorems, 0 offences, verification run of 2026-07-22 on an isolated build host, content-addressed at the same sources); the certified-fragment keystone (checkPf\_sound\_frag, theory bern\_tr\_splICE, 20 theorems, 0 offences, same run) consumes it at the SYZGY wire arm, this rule's target relation.

HOL receipts are documentary: quoted results of hol-strict runs and census rows from the HOL4 development's build evidence, not minted receipt artefacts. A HOL receipt store (the Lean store's twin) is named future work.

## Proof

Genre: alias rule (tier 3) — a respelling template. An alias owes the book five artefacts: the verified  $1 \rightarrow 1$  unpack, the filled-in application of the target rule, the payload-transport table, the exact algebraic identity that makes the respelling correct, and the soundness corollary through the target rule's lemma. All five follow — and this alias is the tier taxonomy's *canonical* case, the one the tier was named for: the unpack is the identity.

**Recipe R27.1** (the alias template). An alias rule  $A$  is warranted by a verified function  $\text{unpack} : \text{Step}_A \rightarrow \text{Step}_T$  into the payload of a *single* target node  $T$  (core or admissible), such that the  $A$ -node and its image conclude the same sequent from the same premises: one node  $\rightarrow$  one node, payload transported, nothing derived. Soundness is then a corollary,  $\text{sound}_A = \text{sound}_T \circ \text{unpack}$ . The wire format may carry  $A$  as a compact register of its own or never carry it at all (producers elaborating before emission, as the SMALLGAIN section records); either way the checker's obligations are the target's, reached through the unpack. This rule takes the second branch in v0: no producer emits the once-contemplated affine coefficient-row register, so no tag is allocated — and the identity unpack makes a register pure wire compactness, purchasable later without semantic motion.

**Recipe R27.2** (the verified unpack — the identity transport). PBOUND's payload carries components, combination term, conclusion term, and the bookkeeping fields *verbatim* as the target's payload does, including the conclusion-form selector. The unpack is therefore not a computation but a re-labelling: the verified object is the direct specialization

$\text{sound}_{\text{PBOUND}} = \text{sound}_{\text{SYZGY}}$  applied to the same fields, re-assembled as the target's step

— in the sources, the body of  $\text{sound\_pBound}$  is one application of  $\text{sound\_syzygy}$  to the step built from PBOUND's own fields. Where SMALLGAIN's unpack computes a weighting, this one computes nothing; that is the tier-3 boundary case made flesh, and it is why the alias relation here is  $1 \rightarrow 1$  at the level of *readings* too (Recipe R27.4).

**Recipe R27.3** (the filled-in application). Under the identity transport the PBOUND node is the following application of the target rule (compare the rule display in the SYZGY section, field for field):

$$\frac{\begin{array}{l} \{\Phi_i \vdash e_i \leq 0\}_{i=1}^n, \quad \Phi \supseteq \Phi_i \text{ conjunct-wise (checked)} \quad \{g_k = 0\}_k \text{ sub-conjuncts of } \Phi \text{ in wire variables} \\ \lambda_i \in \mathbb{Q}_{\geq 0} \quad \nu_k \in \mathbb{Q} \quad c \equiv \sum_i \lambda_i e_i + \sum_k \nu_k g_k \text{ (exact canonical polynomial)} \\ \Psi \in \{c \leq 0, \quad e \geq 0 \text{ where } c = -e, \quad l \leq r \text{ where } c = l - r\} \end{array}}{\Phi \vdash \Psi} \quad \text{SYZGY}$$

where  $\Psi$  is whichever reading of  $c \leq 0$  the shared selector declares:  $(Z \leq) c \leq 0$  itself;  $(G) e \geq 0$  where  $c = -e$ ;  $(L \leq) l \leq r$  where  $c = l - r$ . Discharging the target's obligations at this instance is immediate — they are *the same obligations on the same data*: entry decoding, nonnegative weights, entry-sourcing (component conclusions and premise equality sub-conjuncts, both polarities on equalities), the exact fold identity, premise containment, conclusion shape/finiteness, and the positive-size wire conditions on premise, conclusion, and component conclusions — the last three families displayed inline in PBOUND's own cell, while in SYZGY's cell the shape/finiteness and positive-size conditions ride the payload (its display carries containment as a trailing line); the obligations are identical either way, only the display convention differs. PBOUND's published register prices the  $e_i$  as *affine* entries (the roster's register note); the displayed premises carry no such restriction, and nothing above consults one (Remark R27.8).

**Recipe R27.4** (payload transport — field for field).

| PBOUND payload             | target (SYZGY) payload                                                   |
|----------------------------|--------------------------------------------------------------------------|
| components                 | components (verbatim)                                                    |
| combination                | combination (verbatim)                                                   |
| conclusion                 | conclusion (verbatim)                                                    |
| denBoundLog2               | denBoundLog2 (verbatim; witness-side claim, zero proof-theoretic weight) |
| preContains                | preContains (verbatim)                                                   |
| conclShape, conclFin       | conclShape, conclFin (verbatim)                                          |
| wiresPos, compPostWiresPos | wiresPos, compPostWiresPos (verbatim)                                    |
| valid                      | valid (the same exact-combination proposition)                           |
| postForm                   | postForm (the same three-reading selector)                               |

Every row is the identity — including the last: since the target rule itself carries the three-reading conclusion selector, the alias inherits all readings with no residue, and the transport is  $1 \rightarrow 1$  at reading level, not merely at node level.

**Proposition R27.5** (the exactness identity). *The respelling is exact definitionally: the unpacked node’s combination identity is the same exact canonical-polynomial identity  $c \equiv \sum_i \lambda_i e_i + \sum_k \nu_k g_k$ , unchanged. What remains to make the three readings correct is the fact that they are one exact  $\mathbb{Q}$  identity re-presented under a sign flip — per entry,  $-e(\sigma) \leq 0 \iff e(\sigma) \geq 0$  and  $l(\sigma) - r(\sigma) \leq 0 \iff l(\sigma) \leq r(\sigma)$  — which is the target rule’s reading-transport lemma, proven once in the SYZYGY section and not re-justified here.*

*Proof.* The first claim is reflexivity of the transported field. The second is the cited lemma (the ordered-field axioms negate-and-flip and add-to-both-sides, packaged as the ge-bridge ring lemma); the alias contributes no polarity argument of its own, which is what keeps the  $1 \rightarrow 1$  relation clean.  $\square$

**Proposition R27.6** (soundness corollary). *If every component sequent is semantically valid, then under the payload’s checked hypotheses the sequent  $\Phi \vdash \Psi$  is semantically valid, for every reading  $\Psi$  the selector admits.*

*Proof.* `sound_pBound` = `sound_syzygy` at the transported (identical) payload data, fed the same component validities. There is no other content — the alias genre working as intended.  $\square$

**Remark R27.7** (why the rule exists at all). Semantically the alias adds nothing to its target; its existence is pragmatic, twice over. *Register:* affine entries admit a compact coefficient-row wire spelling, and bound nodes are the bulk commodity of produced certificates — the compact register is worth a tag. *Readings at the seams:* the (G) reading makes a nonnegativity premise (as `ReLU-Pos` demands,  $h \geq 0$ ) reachable directly from bound facts — the once-contemplated standalone  $\geq$ -bridge rule dissolved into the conclusion selector instead — and the (L $\leq$ ) reading hands interval-shaped consumers (`LiRPA`’s endpoint premises) their literal atom with no `ARITHATOM` re-arrangement node in between. Producers get the convenient conclusion shape; the kernel keeps exactly one combination argument.

**Remark R27.8** (the affine restriction is register, not soundness). The register’s “affine entries” — the roster note’s pricing vocabulary, appearing in neither the displayed premises nor the statement — names the wire spelling the rule is priced for, and is not a checked side condition: the combination replay is degree-blind, and the soundness argument (Proposition R27.6) never consults linearity. A higher-degree entry simply belongs to the target rule’s own spelling — what would refuse it is the published register’s compact coefficient-row spelling, an encoding fact of that format (asserted at its register, not displayed here), never the checker. Publishing the restriction beside the rule, while the checker enforces only what soundness needs, mirrors the `FARKAS` page’s linearity note — the register tells producers what the format prices; the checker tells them what truth requires.

| proof step                               | formal anchor                                                                                                                                                                                      |

| wire placement                           | <code>RuleTag.pBound</code> ; no wire tag allocated in <code>v0</code> — producers elaborate before emission (the template’s second branch), and the emit path refuses the rule accordingly        |

## Rule 28. PSDCERTTRI (admissible rule)

### The rule (Steele metanotation)

as realized in the mechanized development; source row: `rules.toml` — *PsdCertTri*. The metanotation statement is typeset by hand for notational quality; its mechanized ground truth is the Lean statement below, extracted from the sources at every build of this book and hash-bound. The rule *roster* is machine-checked (every mechanized rule tag round-trips to exactly one catalogue row); the statement *text* is editorial, checked by eye against the extracted Lean beside it.

$$\frac{\begin{array}{l} A \in \mathbb{Q}^{n \times n} \text{ symmetric} \\ Z \text{ upper-triangular, } Z_{ii} > 0 \quad A \cdot Z \text{ lower-triangular, } (A \cdot Z)_{ii} > 0 \text{ (recomputed exactly)} \quad p_1, \dots, p_n \text{ payload terms} \\ c \equiv -\sum_{i,j} A_{ij} p_i p_j \text{ (exact canonical polynomial)} \quad \Psi \in \{c \leq 0, Q \geq 0 \text{ where } c = -Q, l \leq r \text{ where } c = l - r\} \end{array}}{\Phi \vdash \Psi} \text{PSDCERTTRI}$$

PSDCERTTRI is the exact tier of the positive-definiteness certificate family: a premise-free rule concluding nonnegativity of the quadratic form  $\sum_{i,j} A_{ij} p_i p_j$  of a symmetric rational matrix  $A$  at a payload term vector, warranted by an untrusted witness  $Z$  passing three decidable syntactic checks —  $A$  symmetric,  $Z$  upper-triangular with positive diagonal, and the product  $A \cdot Z$  (recomputed exactly, one sparse multiply) lower-triangular with positive diagonal. Those premises are a theorem-strength certificate of  $A \succ 0$ : the congruence  $Z^T(AZ)$  collapses to a positive diagonal, and positivity transports back through the invertible  $Z$ . The matrix-witness check is division-free,  $O(\alpha n^2)$  multiplications ( $\alpha$  average nonzeros per row), and runs in  $\mathbb{Z}$  on integer inputs.

A producer reaches for it wherever a proof obligation is “this explicit matrix is positive (semi)definite” — Lyapunov and storage-function certificates, energy quadratic forms, elimination-free replacements for exact rational LDL factorization, whose  $O(n^3)$  divisions-with-fill-in it displaces. The witness is produced off-stage (a float Cholesky, exact elimination, anything); soundness never consults its accuracy — a forged  $Z$  can only refuse. The concluded fact enters the logic through the same conclusion-form selector as SYZGY (raw zero-form, the flipped  $Q \geq 0$  reading, or a literal  $l \leq r$  split), so it slots directly into SYZGY/FARKAS combinations as a component conclusion; strictness is deliberately dropped at the formula boundary (a premise-free atom carries no  $p \neq 0$ ), so the in-logic fact is  $\succ$ -shaped even though the matrix-side theorem is strict.

What the checker recomputes: the three matrix checks entrywise over exact  $\mathbb{Q}$ , and — the recompute pattern — that the payload conclusion term's canonical polynomial IS the negated quadratic form  $-\sum_{i,j} A_{ij} p_i p_j$  built from the payload terms (in either the wire-keyed or the wire-coordinate polynomial space). What breaks without each hypothesis: without symmetry the congruence argument dies and the premises say nothing about the quadratic form; without the  $Z$  diagonal signs the product argument loses invertibility or positivity (the two sign families are determinant-linked — for an indefinite  $A$ , flipping a column to repair one violates the other); the  $AZ$  pattern and sign checks are the content itself, and for an indefinite  $A$  no witness whatsoever passes; without the conclusion identity the posted atom could be unrelated to  $A$ ; the shape/finiteness/positive-size fields on the conclusion are the standard evaluability-and-vacuity discipline (a zero-size wire satisfies atoms vacuously, and the positive-size field refuses that vacuous surface). The proof section carries the family preamble and walks these in order.

**notes** Provenance: the triangular-inverse method is due to David “davidad” Dalrymple; Geoffrey Irving derived and published the rounding-tolerant integer analysis and formalized that variant at scale (a certified 65536-node spectral expander) — see the proof section's citations. The kernel development here is an independent proof of the exact tier. Wire tag: deferred to the payload-window allocation; the emit path refuses the rule until allocated.

### Lean statement

BernsteinLogic.Soundness . **sound\_psdCertOf**

statement bound

```
-- The shared PsdCert semantic lemma: from the abstract rational-points
quadratic-form fact (supplied per-variant by the PsdCert bridge
theorems), through the checked conclusion identity, to sequent validity
at every reading of `syzygyConclusionForm`. -/
theorem sound_psdCertOf {H : Hypernet} {seq : Sequent} {a : Nat}
  {M : Fin a → Fin a → ℚ} {ts : List Term} {conclusion : Term}
  (hpsd : ∀ x : Fin a → ℚ, 0 ≤ PsdCert.finQSum a fun i =>
    PsdCert.finQSum a fun j => M i j * x i * x j)
  (hconcl : PsdCert.conclCheck a M ts conclusion = true)
  (hshape : ∃ s, conclusion.bshape H = some s)
  (hfin : conclusion.finWires H)
  (hwpos : ∀ w ∈ conclusion.freeWires,
    ∃ τ, H.wireType w = some τ ∧ 0 < Shape.totalSize τ.shape)
  (hform : syzygyConclusionForm conclusion seq.post) :
  seq.semanticallyValid H
```

## BernsteinLogic.Soundness . sound\_psdCertTri

statement bound

```

/-- PsdCertTri soundness: the /T witness warrants  $A > 0$  over  $\mathbb{R}$ 
(`PsdCert.checkTri_posDef`, davidad's triangular-inverse theorem), whose
quadratic form is nonnegative at every rational point. -/
theorem sound_psdCertTri {H : Hypernet} {seq : Sequent} {a : Nat}
  {A Z : Fin a → Fin a →  $\mathbb{Q}$ } {ts : List Term} {conclusion : Term}

  (hform : syzygyConclusionForm conclusion seq.post) :
  seq.semanticallyValid H

```

**The matrix theorems (mathlib side).** The chain from witness check to consumable fact: the congruence collapse and transport lemmas prove the triangular-witness theorem; checkTri\_posDef bridges the executable Bool check to positive definiteness of the  $\mathbb{R}$ -cast; and the rational-points corollary is the exact shape the rule soundness lemma consumes. Soundness never consults witness accuracy — every hypothesis of every theorem below is a checked premise, so a forged witness can only fail a decidable check.

## BernsteinLogic.PsdCert . congruence\_eq\_diagonal

statement bound

```

/-- The congruence  $Z^H * (A * Z)$  collapses to a diagonal matrix when `Z` is
upper-triangular and `A * Z` is lower-triangular, and its diagonal entries
are the products of the two matrices' diagonals. -/

```

## Correspondence (Steele display ↔ Lean)

**reviewer-certified against the displayed texts** The dictionary below is a reviewer-certified statement of how the mechanized statements above interpret the displayed rule: display metavariable  $\mapsto$  Lean binder, each display hypothesis  $\mapsto$  the premise or side condition carrying it, the display conclusion  $\mapsto$  the goal — with any deliberate difference in width between display and mechanization named outright. Certification is recorded as a hash triple over (the displayed cell, the extracted statement texts, this dictionary's own text); if any of the three changes, this block turns amber until a reviewer re-certifies. The correspondence claim itself remains editorial — reviewer-grade, not machine-checked; its machine-checked successor types each soundness statement against the rule as a structured object, and supersedes this block per rule as it lands.

Judgment frame as in Ax. This dictionary is the trio's template; /DD and /K differ in the witness row alone.

- $n \mapsto a : \text{Nat}; A \mapsto A; Z \mapsto Z$  (both  $\text{Fin } a \rightarrow \text{Fin } a \rightarrow \mathbb{Q}$ );  $p_1, \dots, p_n \mapsto ts : \text{List Term}; c \mapsto \text{conclusion} : \text{Term}$ .
- premise-freeness  $\mapsto$  silence, the PCONSTEXACT representation: no hypothesis mentions seq.pre, so  $\Phi$  is arbitrary — the NORM convention of the roster note, carried structurally.
- the three displayed matrix rows (symmetry; upper-triangular  $Z$  with positive diagonal; lower-triangular  $A \cdot Z$  with positive diagonal, recomputed exactly)  $\mapsto$  the single Boolean witness  $\text{hwit} : \text{PsdCert.checkTri } a \ A \ Z = \text{true}$ , whose definition (displayed above) recomputes all three. The mathematics enters through the certified-alongside bridge:  $\text{checkTri\_posDef}$  warrants  $A \succ 0$  over  $\mathbb{R}$ , and  $\text{sound\_psdCertTri}$  consumes only its rational-points quadratic-form corollary  $\text{checkTri\_quadForm\_nonneg}$  — the displayed strictness drop at the formula boundary, visible in the statement's type.

- the canonical-polynomial row  $c \equiv -\sum_{i,j} A_{ij}p_i p_j \mapsto \text{hconcl} : \text{conclCheck } a \text{ A ts conclusion} = \text{true}$  — the identity is checked on canonical forms by either of two certified routes (the idx-free toPoly replay of `conclCheckCore`, or the coordinate-indexed `conclCheckW`), and `sound_psdCertOf` discharges both.
- $\Psi \in \{c \leq 0; Q \geq 0 \text{ where } c = -Q; l \leq r \text{ where } c = l - r\} \mapsto \text{hform} : \text{syzygyConclusionForm conclusion seq.post}$  — the certified selector is literally that three-membered disjunction, reading the conclusion term's head syntactically (shared with `SYZGY` and `PBOUND`).
- with no displayed row: the evaluability pack — `hshape` (the conclusion has a broadcast shape in  $\mathbb{H}$ ), `hfin` (its wires are finite-typed), and `hwpos` (every free wire positively sized). The display omits all three; the certified statement demands them, and `hwpos` is the same vacuous-surface refusal the `FARKAS` display carries inline and the `LiRPA` linkage builds in.

Width note: elementwise atom semantics batch the conclusion (the roster note), so the display's scalar reading is the singleton case of the certified one; conversely the certified statement never uses witness accuracy beyond the Boolean check — a forged  $Z$  refuses, never falsely accepts — and no hypothesis is unused.

## Lean verifier receipts

module `BernsteinLogic.Soundness`; bound build `a20d90e66c13...` (bound from receipt `a9c0e34d3e3c9c8c`, 2026-08-03T21:30:36Z). A receipt records that named checking layers accepted a build: (module, compiled-artifact SHA-256, environment SHA-256, checker layers), minted when the checking gate ran; the store receipts attesting the bound build are listed with the layers each run credited. Nothing here asks the reader to trust the store: every layer is an independently runnable program over the quoted sources — rebuild the module and re-run the checkers to reproduce the verdict. Receipts attesting superseded builds credit no layer and are omitted from this rendering (the count of omissions, if any, is noted below).

**HOL verifier receipts**

documentary hol-strict CLEAN: theory bern\_tr\_soundpsd, 4 theorems, 0 cheat-tagged, 0 nonstandard axioms (whitelist: DISK\_THM; the four bool axioms), 249-theory ancestry — verification run of 2026-07-22 on an isolated build host, against a content-addressed checkout of the exact sources cited here (git blob c01e0b0c...). The twins mirror the Lean statements clause-for-clause per the script's statement-fidelity inventory: the shared semantic spine (sound\_psdCert0f) runs from the abstract rational-points quadratic-form fact through the checked conclusion identity to sequent validity at every reading of the shared conclusion-form selector, and the per-shape corollary discharges that fact via the ported triangular-witness bridge (psdCheckT\_quadForm, theory bern\_psd, where the witness check itself — psdCheckT — is ported with kernel-EVAL receipts). The payload record and its wellformedness arm ride the ported proof-object stratum (theory bern\_tr\_catdata2, 272 theorems, 0 offences, same run).

HOL receipts are documentary: quoted results of hol-strict runs and census rows from the HOL4 development's build evidence, not minted receipt artefacts. A HOL receipt store (the Lean store's twin) is named future work.

**Proof**

Genre: admissible rule (tier 2) — a recipe by *reduction to verified machinery* (the PCONSTEXACT pattern): no catalogue derivation of an exact matrix-positivity fact exists, which is the trio's point; each rule discharges against a named kernel-verified matrix theorem. This section also states the certificate-family preamble the PSDCERTDIAG and PSDCERTKERNEL sections reference.

**Recipe R28.1** (the PSD-certificate family — shared shape). All three rules certify positivity of a symmetric matrix  $A \in \mathbb{Q}^{n \times n}$  from an *untrusted witness*, by decidable syntactic checks in exact rational arithmetic — no divisions, no pivoting, no floating point on the trusted side. The shared discipline:

- (i) *Soundness never consults the witness's accuracy.* The conclusion is a theorem of the checked premises; a forged or degraded witness can only cause a false REJECT, never a false ACCEPT. Producers may therefore run arbitrary float factorizations off-stage.
- (ii) *The in-logic conclusion is the quadratic form, not the matrix.* The formula language has no matrix atoms, so the rule's conclusion is nonnegativity of  $Q(p) = \sum_{i,j} A_{ij} p_i p_j$  at a payload term vector  $p_1, \dots, p_n$ : the payload conclusion term  $c$  is checked — by exact canonical-polynomial identity, the recompute pattern — to  $be - \sum_{i,j} A_{ij} p_i p_j$ , and the sequent's posted formula is one of three readings of  $c \leq 0$  (the raw zero-form; the flipped  $Q \geq 0$ ; the literal  $l \leq r$  where  $c = l - r$ ) — the same conclusion-form selector displayed in the SYZGY section, so the fact slots directly into SYZGY/FARKAS combinations as a component conclusion.
- (iii) *Strictness is deliberately dropped at the formula boundary.* The matrix theorems certify  $A \succ 0$  (for /T and /DD), but the premise-free atom ships the  $\succ$ -shaped fact: strict positivity of  $Q(p)$  would need  $p \neq 0$ , which no premise-free atom carries.
- (iv) *The rules are premise-free;*  $\Phi$  is arbitrary (a fact holding in the empty context holds under any premise). Elementwise atom semantics batch the conclusion: at tensor-shaped payload terms, entry  $e$  of the conclusion is the quadratic form at the terms' entry- $e$  values, so one node states a family of instances.

The rewrite, per rule, is degenerate in the PCONSTEXACT sense: one node, zero catalogue premises, discharged by the rule's matrix theorem composed with the shared transport lemma (sound\_psdCert0f) that carries “PSD over  $\mathbb{R}$ ” through “nonnegative at every rational point” and the checked polynomial identity to the posted formula.

**Recipe R28.2** (the  $\text{PSDCERTTRI}$  instance). Witness:  $Z \in \mathbb{Q}^{n \times n}$ . Checked premises (all decidable, all exact):  $A$  symmetric;  $Z$  upper-triangular with positive diagonal;  $M := AZ$  (recomputed exactly, one sparse multiply) lower-triangular with positive diagonal. Then

$$\frac{\text{checkTri}(A, Z) = \text{true} \quad c \equiv -\sum_{i,j} A_{ij} p_i p_j}{\Phi \vdash \Psi} \quad \text{PSDCERTTRI} \xrightarrow{\sim} \text{discharged by sound\_psdCertTri},$$

with  $\Psi$  any reading of  $c \leq 0$  per the preamble. The matrix-witness check costs  $O(\alpha n^2)$  multiplications ( $\alpha$  = average nonzeros per row of  $A$ ) plus  $O(n^2)$  sign/zero inspections, division-free; on integer inputs it runs entirely in  $\mathbb{Z}$  with  $\{*, +, <\}$ . (The conclusion-identity recompute is additional, and its cost tracks the payload terms' polynomial sizes, not  $n$  alone.)

**Proposition R28.3** (matrix warrant). *If  $A$  is symmetric,  $Z$  upper-triangular with  $Z_{ii} > 0$ , and  $AZ$  lower-triangular with  $(AZ)_{ii} > 0$ , then  $A \succ 0$  over  $\mathbb{R}$ .*

*Proof.* Let  $B := Z^T(AZ)$ . As a product of two lower-triangular matrices ( $Z^T$  and  $AZ$ ) it is lower-triangular; since  $Z^T AZ$  is a congruence of the symmetric  $A$  it is also symmetric; hence  $B$  is *diagonal*, and the sum  $B_{ii} = \sum_k Z_{ki}(AZ)_{ki}$  collapses to the single term  $Z_{ii}(AZ)_{ii} > 0$ . So  $B \succ 0$ . Moreover  $\det Z = \prod_i Z_{ii} > 0$  makes  $Z$  invertible, and  $A = Z^{-T} B Z^{-1} \succ 0$  by congruence. (This is the route the kernel proof takes — `congruence_eq_diagonal` then `posDef_of_congruence_posDef` — avoiding leading principal minors; the classical alternative reads  $A = MZ^{-1}$  as an LU factorization with positive-diagonal factors and applies Sylvester's criterion [115].)  $\square$

*Remark R28.4* (each hypothesis, and what removing it admits). *Symmetry of  $A$* : without it  $Z^T(AZ)$  need not be symmetric, the diagonal-collapse argument dies, and the quadratic form reads only the symmetric part of  $A$  — the premises would say nothing about it. *Upper-triangularity and positive diagonal of  $Z$* : triangularity is the cheapest syntactic invertibility certificate ( $\det Z = \prod Z_{ii}$ ), and the diagonal signs feed  $B_{ii} > 0$ ; the two sign families are determinant-linked: for an indefinite  $A$  — a genuinely negative pivot — “repairing” the  $AZ$  diagonal sign by flipping the offending column of  $Z$  only moves the violation into  $Z$ 's own diagonal check ( $A = \text{diag}(1, -1)$ ,  $Z = \text{diag}(1, z)$ : making  $-z$  positive forces  $z < 0$ ; when  $A$  is in fact positive definite, a flip can repair both checks at once — acceptance working as intended, not a leak). *The pattern and sign checks on  $AZ$* : this is the entire content — the diagonal of  $AZ$  carries the pivot signs of  $A$ , and for an indefinite  $A$  no witness whatsoever passes (by Proposition R28.3 an accepting witness would prove  $A \succ 0$ ). *The conclusion identity*: without the recomputed polynomial check the posted atom could be an arbitrary formula unrelated to  $A$ .

*Remark R28.5* ( $/T$  needs an exact witness — the honest split with  $/DD$ ). The natural producer emits  $Z \approx$  an inverse transposed Cholesky factor. A *rounded* such  $Z$  makes the strictly-upper entries of  $AZ$  small but nonzero, and  $/T$ 's pattern check rightly refuses. An exact witness always exists when  $A \succ 0$ , and rationally:  $\text{LDL}^T$  elimination gives  $A = \text{LDL}^T$  with unit lower-triangular rational  $L$  and positive rational diagonal  $D$ , so  $Z := L^{-T}$  is rational upper-triangular with positive diagonal and  $AZ = LD$  is lower-triangular with positive diagonal — clear denominators columnwise if integer entries are wanted (each column is determined up to positive scale) — but the entries grow like scaled minors, i.e.  $\text{LDL}$ -style bit growth. (The Cholesky factor itself is generally irrational; the  $\text{LDL}$  route is the rational construction.) At sizes where that growth bites, the rounding-tolerant companion  $\text{PSDCERTDIAG}$  is the production tier; at moderate sizes  $/T$ 's  $O(\alpha n^2)$  check wins the clock. Neither tier ever risks soundness in the trade — only completeness margin moves.

*Remark R28.6* (provenance). The triangular-inverse method is due to David “davidad” Dalrymple [56]; Geoffrey Irving derived the rounding-tolerant integer variant and published the certificate analysis [123], then formalized that variant in Lean at scale (a certified 65536-node spectral expander) in the course of a sorting-network formalization [122]. The kernel development cited here is an independent in-house proof of the exact tier, grown to the  $/DD$  and  $/K$  companions.

## Rule 29. PSDCERTDIAG (admissible rule)

### The rule (Steele metanotation)

as realized in the mechanized development; source row: `rules.toml` — *PsdCertDiag*. The metanotation statement is typeset by hand for notational quality; its mechanized ground truth is the Lean statement below, extracted from the sources at every build of this book and hash-bound. The rule *roster* is machine-checked (every mechanized rule tag round-trips to exactly one catalogue row); the statement *text* is editorial, checked by eye against the extracted Lean beside it.

$$\frac{\begin{array}{l} A \in \mathbb{Q}^{n \times n} \text{ symmetric} \quad Z \text{ upper-triangular, } Z_{ii} > 0 \\ B := Z^T A Z \text{ strictly row-diagonally dominant (recomputed exactly)} \quad p_1, \dots, p_n \text{ payload terms} \\ c \equiv -\sum_{i,j} A_{ij} p_i p_j \text{ (exact canonical polynomial)} \quad \Psi \in \{ c \leq 0, \ Q \geq 0 \text{ where } c = -Q, \ l \leq r \text{ where } c = l - r \} \end{array}}{\Phi \vdash \Psi} \text{PSDCERTDIAG}$$

PSDCERTDIAG is the rounding-tolerant tier of the positive-definiteness certificate family (the family discipline — untrusted witness, quadratic-form conclusion through SYZGY's conclusion-form selector, strictness dropped at the formula boundary, premise-freedom — is stated once in the PSDCERTTRI section). Here the checked premises are:  $A$  symmetric;  $Z$  upper-triangular with positive diagonal; and the congruence  $B := Z^T A Z$ , recomputed exactly by the checker, strictly row-diagonally dominant (positive diagonal implied, since the off-row absolute sum is nonnegative). A symmetric strictly dominant matrix is positive definite — the Gershgorin-circle reading; the kernel proof is a self-contained arithmetic-geometric-mean regrouping of the quadratic form — and positivity transports back through the invertible  $Z$ .

This is the tier a real producer feeds:  $Z := \lceil 2^s R^{-1} \rceil$  rounded from an off-stage float Cholesky  $A \approx R^T R$  works directly, with the required scale  $s$  growing only logarithmically in dimension and input scale rather than tracking any accuracy target — witness entries encode in  $s + O(\log^+ \|R^{-1}\|_{\max})$  bits (scale exponent plus the factorization's own magnitude), dimension entering only through the logarithm, where the exact  $/T$  witness inherits minor-scale bit growth. What a too-coarse witness costs is only completeness margin: the check fails closed and the producer retries finer, with soundness never in play. The price relative to  $/T$  is the  $O(n^3)$  congruence product — on bounded-width integers, embarrassingly parallel, still division-free.

What breaks without each hypothesis: without symmetry of  $A$  the regrouping step (which folds the dominance envelope using  $B_{ij} = B_{ji}$ ) fails and row dominance alone bounds nothing about the form; without strictness the matrix warrant  $A \succ 0$  would overclaim on singular matrices (a path-graph Laplacian is weakly dominant with the constants in its kernel — the  $\succ$ -shaped posted atom would survive, but the strict theorem  $/K$  consumes on its inner block would not); without exact recomputation of  $B$  a wire-supplied congruence could be dominant while unrelated to  $A$ ; the  $Z$  checks are, as in  $/T$ , the cheapest syntactic invertibility certificate. The conclusion identity and evaluability fields carry the same discipline as  $/T$ . The proof section walks these in order.

### Lean statement

BernsteinLogic.Soundness . sound\_psdCertDiag

statement bound

```
/-- PsdCertDiag soundness: the /DD witness warrants  $A > 0$  over  $\mathbb{R}$ 
(`PsdCert.checkDiag_posDef`, the diagonal-dominance congruence). -/
theorem sound_psdCertDiag {H : Hypernet} {seq : Sequent} {a : Nat}

  (hform : syzygyConclusionForm conclusion seq.post) :
  seq.semanticallyValid H
```

**The dominance core.** `posDef_of_dominant` is the self-contained finite-sum argument (no spectral machinery): off-diagonal mass retreats into its arithmetic-geometric-mean envelope and symmetry folds the envelope onto the diagonal, leaving  $\sum_i (B_{ii} - \sum_{j \neq i} |B_{ij}|) x_i^2 > 0$ . `posDef_of_dd_witness` composes it with the congruence transport displayed in the PSDCERTTRI section; `checkDiag_posDef` bridges the executable check, and the rational-points corollary feeds the rule lemma.

BernsteinLogic.PsdCert . posDef\_of\_dominant

statement bound

```
/-- **The /DD dominance core**: a symmetric strictly row-diagonally
dominant real matrix is positive definite. Self-contained Finset
algebra — the AM–GM regrouping: off-diagonal mass retreats into
```

```

`Σi (Σ{j≠i} |Bij|)·xi2` by symmetry, leaving `Σi (Bii - Σ{j≠i}|Bij|)·xi2`,

```

## Correspondence (Steele display ↔ Lean)

**reviewer-certified against the displayed texts** The dictionary below is a reviewer-certified statement of how the mechanized statements above interpret the displayed rule: display metavariable  $\mapsto$  Lean binder, each display hypothesis  $\mapsto$  the premise or side condition carrying it, the display conclusion  $\mapsto$  the goal — with any deliberate difference in width between display and mechanization named outright. Certification is recorded as a hash triple over (the displayed cell, the extracted statement texts, this dictionary's own text); if any of the three changes, this block turns amber until a reviewer re-certifies. The correspondence claim itself remains editorial — reviewer-grade, not machine-checked; its machine-checked successor types each soundness statement against the rule as a structured object, and supersedes this block per rule as it lands.

Verbatim the `PsDCertTri` dictionary — premise-free silence, the same `ts/conclusion` binders, the same `conclCheck` and `syzygyConclusionForm` rows, the same undisplayed evaluability pack (`hshape`, `hfin`, `hwpos`) — except the witness row: the displayed congruence  $B := Z^T A Z$  strictly row-diagonally dominant  $\mapsto$  `hwit : PsdCert.checkDiag a A Z = true`, entering through `checkDiag_posDef` and consumed as its rational-points corollary `checkDiag_quadForm_nonneg`. The shared assembly is one certified lemma, `sound_psdCertOf`, visible above — the dictionary's claim that the trio differs only in the witness is itself a fact of the statements, not editorial.

## Lean verifier receipts

module `BernsteinLogic.Soundness`; bound build `a20d90e66c13...` (bound from receipt `a9c0e34d3e3c9c8c`, 2026-08-03T21:30:36Z). A receipt records that named checking layers accepted a build: (module, compiled-artifact SHA-256, environment SHA-256, checker layers), minted when the checking gate ran; the store receipts attesting the bound build are listed with the layers each run credited. Nothing here asks the reader to trust the store: every layer is an independently runnable program over the quoted sources — rebuild the module and re-run the checkers to reproduce the verdict. Receipts attesting superseded builds credit no layer and are omitted from this rendering (the count of omissions, if any, is noted below).

## HOL verifier receipts

**documentary** hol-strict CLEAN: theory bern\_tr\_soundpsd, 4 theorems, 0 cheat-tagged, 0 nonstandard axioms (whitelist: DISK\_THM; the four bool axioms), 249-theory ancestry — verification run of 2026-07-22 on an isolated build host, against a content-addressed checkout of the exact sources cited here (git blob c01e0b0c...). The shared semantic spine (sound\_psdCert0f) is displayed in the /Tri section per the family-preamble convention; this corollary discharges the quadratic-form fact via the ported congruence-plus-row-dominance bridge (psdCheckDD\_quadForm, theory bern\_psd, where the witness check itself — psdCheckDD — is ported with kernel-EVAL receipts). The payload record and its wellformedness arm ride the ported proof-object stratum (theory bern\_tr\_catdata2, 272 theorems, 0 offences, same run).

HOL receipts are documentary: quoted results of hol-strict runs and census rows from the HOL4 development's build evidence, not minted receipt artefacts. A HOL receipt store (the Lean store's twin) is named future work.

## Proof

Genre: admissible rule (tier 2) — reduction to verified machinery. The certificate-family preamble — untrusted witness, quadratic-form conclusion through the SYZGYV conclusion-form selector, strictness dropped at the formula boundary, premise-freedom, elementwise batching — is stated in the PSDCERTTRI section (its first recipe) and applies verbatim; only the witness check differs here.

**Recipe R29.1** (the PSDCERTDIAG instance). **Witness:**  $Z \in \mathbb{Q}^{n \times n}$ . **Checked premises:**  $A$  symmetric;  $Z$  upper-triangular with positive diagonal; and the congruence  $B := Z^T A Z$  — *recomputed exactly by the checker* — strictly row-diagonally dominant:  $\sum_{j \neq i} |B_{ij}| < B_{ii}$  for every  $i$ . (Positivity of the diagonal is implied: the off-row sum is  $\geq 0$ .) Then

$$\frac{\text{checkDiag}(A, Z) = \text{true} \quad c \equiv -\sum_{i,j} A_{ij} p_i p_j}{\Phi \vdash \Psi} \text{PSDCERTDIAG} \rightsquigarrow \text{discharged by sound\_psdCertDiag.}$$

The matrix-witness check costs  $O(\alpha n^2 + n^3)$  multiplications ( $\alpha$  the average nonzeros per row of  $A$ , as at /T) with the product  $AZ$  materialized once (the  $Z^T(AZ)$  congruence is the  $n^3$  term; the reference check displayed below inlines the product entrywise for readability — it is the specification, not the cost model) on integers of *bounded* width — input bits plus twice the witness bits plus  $O(\log n)$  for the nested sums — embarrassingly parallel, still division-free.

**Proposition R29.2** (matrix warrant). *A symmetric real matrix  $B$  with  $\sum_{j \neq i} |B_{ij}| < B_{ii}$  for all  $i$  is positive definite; hence if additionally  $Z$  is upper-triangular with positive diagonal and  $B = Z^T A Z$  for symmetric  $A$ , then  $A \succ 0$ .*

*Proof.* For  $x \neq 0$ , split the quadratic form and bound each off-diagonal term by its arithmetic–geometric–mean envelope,  $x_i B_{ij} x_j \geq -|B_{ij}|(x_i^2 + x_j^2)/2$ ; folding the envelope's two symmetric halves by  $B_{ij} = B_{ji}$  gives

$$x^T B x \geq \sum_i \left( B_{ii} - \sum_{j \neq i} |B_{ij}| \right) x_i^2 > 0.$$

(The kernel proof is exactly this self-contained finite-sum argument — posDef\_of\_dominant — with no spectral machinery. The classical reading: strict dominance with positive diagonal places every Gershgorin disc in the open right half-plane, and symmetry makes the spectrum real, hence positive [88, 115, 230].) Transport through the invertible  $Z$  as in the /T proof (posDef\_of\_congruence\_posDef) yields  $A \succ 0$ .  $\square$

**Remark R29.3** (what each hypothesis is doing). *Symmetry of  $A$*  makes  $B$  symmetric by construction, which the envelope-folding step consumes ( $B_{ij} = B_{ji}$ ) — row dominance of a nonsymmetric matrix bounds neither the symmetric part's rows nor the form. *Triangularity + positive diagonal of  $Z$*  is, as in /T, only the cheapest syntactic invertibility certificate — invertibility is all the transport step needs, and triangularity is what the natural producer emits anyway. *Strict dominance* is the content of the strict tier: weakening it to non-strict admits singular  $B$  (e.g. the graph Laplacian of a path: weakly dominant, kernel = constants), and the matrix warrant  $A \succ 0$  would overclaim — the posted  $\succ$ -shaped atom would in fact survive, but the strict theorem is what PSDCERTKERNEL consumes on its inner block to confine kernels, and that consumer admits no slack. *Exact recomputation of  $B$* : the congruence is never taken from the certificate — a wire-supplied  $B$  could be dominant while unrelated to  $A$ .

**Remark R29.4** (rounding tolerance — why this is the production tier). Feed  $Z := \lceil 2^s R^{-1} \rceil$  from an off-stage float Cholesky  $A \approx R^T R$ : writing  $Z = 2^s R^{-1} + E$  with rounding  $|E_{ij}| \leq \frac{1}{2}$ , exact expansion (against an exact factorization) gives  $B = Z^T A Z = 4^s I + 2^s (RE + (RE)^T) + E^T A E$  — entrywise contamination  $O(2^s n \|R\|_{\max} + n^2 \|A\|_{\max})$ , off-row dominance sums one factor of  $n$  larger — plus the image of the float residual  $\Delta := A - R^T R$  — the term  $Z^T \Delta Z$ , of normalized leading size  $R^{-T} \Delta R^{-1}$  — whose control is a mantissa requirement of order  $\log_2 \kappa(A) + O(\log n)$  bits on the factorization (the dimension guard bits of the standard backward-error bound), not on the witness. Strict dominance therefore holds once  $2^s$  clears a polynomial in

$n$  times the input scales: a scale exponent  $s = O(\log n + \log \|R\|_{\max})$  suffices (sharp constants in the cited certificate analysis), so the witness *scale* grows only *logarithmically* in dimension and scale and never tracks an accuracy target; the witness *entries* encode in  $s + O(\log^+ \|R^{-1}\|_{\max})$  bits — the second term is the factorization’s own magnitude ( $Z$  rounds  $2^s R^{-1}$ ), present at any scale, and no accuracy target either. Contrast /T, whose exact witness inherits minor-scale bit growth. What a too-coarse  $Z$  costs is only completeness margin: the check fails closed, and the producer retries at a finer scale with soundness never in play. This rounded-integer-witness shape is the one Irving analysed and formalized at scale [122, 123]; the underlying tolerance phenomenon is the factor-width/scaled-diagonal-dominance circle of ideas [24] — context, not a characterization: that theorem equates factor-width two with scaled diagonal dominance of  $A$  *itself* (diagonal scaling only), while /DD checks dominance of the congruence target  $B = Z^T A Z$  for arbitrary triangular  $Z$ , and so accepts matrices far outside the SDD class — with an exact LDL witness the congruence target is diagonal, so /DD’s exact-witness reach is *every* rational SPD matrix, while e.g. the  $3 \times 3$  equicorrelation matrix with off-diagonal  $\rho \in (\frac{1}{2}, 1)$  is SPD but not SDD under any positive diagonal scaling.

*Remark R29.5* (the /T—/DD complementarity, stated once). Same witness idea, dual regimes: /T is exact-witness,  $O(\alpha n^2)$ , and wins at moderate sizes and exact-by-construction witnesses; /DD tolerates any rounding at  $O(n^3)$  bounded-width parallel arithmetic and wins at scale. A producer holding a float factorization reaches for /DD by default and /T when it can clear denominators cheaply. Both refuse indefinite  $A$  against every witness.

## Rule 30. PSDCERTKERNEL (admissible rule)

### The rule (Steele metanotation)

as realized in the mechanized development; source row: `rules.toml` — `PsdCertKernel`. The metanotation statement is typeset by hand for notational quality; its mechanized ground truth is the Lean statement below, extracted from the sources at every build of this book and hash-bound. The rule *roster* is machine-checked (every mechanized rule tag round-trips to exactly one catalogue row); the statement *text* is editorial, checked by eye against the extracted Lean beside it.

$$\frac{\begin{array}{l} A \in \mathbb{Q}^{(m+k) \times (m+k)}, \text{ kernel coordinates last} \quad L := (I \mid N), N \in \mathbb{Q}^{m \times k} \\ A = L^\top B L \text{ entrywise exactly} \quad B \in \mathbb{Q}^{m \times m} \text{ with a /T-or-/DD inner witness } Z \quad p_1, \dots, p_{m+k} \text{ payload terms} \\ c \equiv -\sum_{i,j} A_{ij} p_i p_j \text{ (exact canonical polynomial)} \quad \Psi \in \{c \leq 0, Q \geq 0 \text{ where } c = -Q, l \leq r \text{ where } c = l - r\} \end{array}}{\Phi \vdash \Psi} \text{PSDCERTKERNEL}$$

PSDCERTKERNEL is the semidefinite member of the certificate family (family discipline in the PSDCERTTRI section): it certifies  $A \succcurlyeq 0$  with an exactly-checked kernel, for the boundary cases the two strict tiers cannot touch — energy forms with conservation laws, graph Laplacians with their all-ones kernel, sharp certificates whose slack vanishes identically. Data:  $A$  over  $\mathbb{Q}^{(m+k) \times (m+k)}$  with the  $k$  kernel coordinates last (the producer applies its permutation before emission — conjugation is index renaming, so the identity-permutation form loses no generality); a rational kernel description  $N$ ; and a leading block  $B$  with a /T-or-/DD inner witness. The checked premise is a single entrywise-exact factorization:  $A = L^\top B L$  for the kernel-completion rows  $L = (I_m \mid N)$  — equivalent, given the inner check's own symmetry verification of  $B$ , to  $(A \text{ symmetric} \wedge A \cdot K = 0 \text{ exactly for } K = (-N; I_k) \wedge \text{leading block} = B)$ , the cross and trailing blocks being forced either way, so a forged  $N$  or  $B$  refuses — plus the strict inner check on  $B$ . Rectangular congruence then gives  $A \succcurlyeq 0$  with the form vanishing exactly on the span of  $K$ : the certificate fixes kernel and rank, not just semidefiniteness.

The kernel data must be exact by necessity, not by preference: the semidefinite-with-kernel matrices form a boundary set with empty interior, so no rounding-tolerant witness for kernel directions can exist — any check tolerant to kernel perturbation also accepts slightly-indefinite matrices. Exact kernel plus rounding-tolerant bulk (the /DD inner witness) is therefore the forced split — tolerance can live nowhere else — and it matches the producers: kernels are semantic (theorems supply  $N$ ), floats only ever touch the bulk witness  $Z$ . Corners are structural:  $k = 0$  degenerates to the inner strict tier;  $m = 0$  forces  $A = 0$ , where the factorization premise is the entire content.

What breaks without each hypothesis: an approximate factorization certifies nothing (the boundary argument above); a merely semidefinite inner block would hide undeclared kernel directions inside  $B$ ; the kernel-coordinates-last convention is pure bookkeeping. What reaches the formula layer is the quadratic-form conclusion — honest for this rule, since it is  $\succcurlyeq$ -shaped — while the checked kernel/rank content becomes formula-expressible only with closed tensor terms (the extension the PCONSTEXACT section records); it is certificate-level assurance meanwhile, deliberately not hand-faked into the formula grammar. The proof section walks these in order.

### Lean statement

BernsteinLogic.Soundness . `sound_psdCertKernel`

statement bound

```
-- PsdCertKernel soundness: the /K witness warrants A ≥ 0 over ℝ
(`PsdCert.checkKernel_posSemidef`, the kernel-completion congruence). -/
theorem sound_psdCertKernel {H : Hypernet} {seq : Sequent} {m k : Nat}
  {A : Fin (m + k) → Fin (m + k) → ℚ} {N : Fin m → Fin k → ℚ}

  {ts : List Term} {conclusion : Term}
  (hwit : PsdCert.checkKernel m k A N B innerT Z = true)
  (hconcl : PsdCert.conclCheck (m + k) A ts conclusion = true)
  (hshape : ∃ s, conclusion.bshape H = some s)
  (hfin : conclusion.finWires H)
  (hwpos : ∀ w ∈ conclusion.freeWires,
    ∃ τ, H.wireType w = some τ ∧ 0 < Shape.totalSize τ.shape)
  (hform : syzygyConclusionForm conclusion seq.post) :
  seq.semanticallyValid H
```

**The rectangular congruence.** `posSemidef_of_factor` is one line — semidefiniteness transports through ANY rectangular congruence, no invertibility anywhere — which is exactly why the factorization premise can carry the whole rule. `checkKernel_posSemidef` bridges the executable check (selecting the /T or /DD theorem for the inner block), and the rational-points corollary feeds the rule lemma.

BernsteinLogic.PsdCert . `posSemidef_of_factor`

statement bound

```

/-- **PsdCertKernel soundness core**: a matrix exhibited as the two-sided
congruence `L^HBL` of a positive-semidefinite block is positive
semidefinite (rectangular congruence; no invertibility anywhere). -/
theorem posSemidef_of_factor {m' n' : Type*} [Fintype m'] [Fintype n']
  {A : Matrix n' n' ℝ} {B : Matrix m' m' ℝ} {L : Matrix m' n' ℝ}
  (hB : B.PosSemidef) (hA : A = L^H * B * L) : A.PosSemidef

```

BernsteinLogic.PsdCert . **checkKernel\_posSemidef**

statement bound

```

/-- `checkKernel` warrants positive semidefiniteness of the ℝ-cast. -/
theorem checkKernel_posSemidef {m k : Nat} {A : Fin (m + k) → Fin (m + k) → ℚ}
  {N : Fin m → Fin k → ℚ} {B : Fin m → Fin m → ℚ} {innerT : Bool}
  {Z : Fin m → Fin m → ℚ}
  (h : checkKernel m k A N B innerT Z = true) : (matR A).PosSemidef

```

BernsteinLogic.PsdCert . **checkKernel\_quadForm\_nonneg**

statement bound

```

/-- /K's consumable corollary. -/
theorem checkKernel_quadForm_nonneg {m k : Nat} {A : Fin (m + k) → Fin (m + k) → ℚ}
  {N : Fin m → Fin k → ℚ} {B : Fin m → Fin m → ℚ} {innerT : Bool}
  {Z : Fin m → Fin m → ℚ}
  (h : checkKernel m k A N B innerT Z = true) (x : Fin (m + k) → ℚ) :
  0 ≤ finQSum (m + k) (fun i => finQSum (m + k) (fun j => A i j * x i * x j))

```

**The executable check — what /K adds.** The kernel-completion rows and the entrywise factorization check; the inner witness reuses checkTri/checkDiag and the conclusion check is shared (both displayed in the PsdCERTTri section).

BernsteinLogic.Core.Catalogue . **kernelExt**

definition bound

```

/-- The kernel-completion row matrix L = (I | N) : m × (m+k). -/
def kernelExt (m k : Nat) (N : Fin m → Fin k → Rat) (a : Fin m)
  (j : Fin (m + k)) : Rat :=
  if h : j.val < m then (if a.val = j.val then 1 else 0)
  else N a (j.val - m, by have := j.isLt; omega)

```

BernsteinLogic.Core.Catalogue . **checkKernel**

definition bound

```

/-- PsdCertKernel witness check (PSD-with-kernel companion): A – over
`Fin (m+k)`, the kernel coordinates LAST – IS the two-sided
kernel-completion congruence L^HBL of its leading block B, entrywise
exactly, plus a T-or-DD inner witness for B. Equivalent to the note's §1
premises (A symmetric ∧ A·K = 0 exactly for K = (-N; I_k) ∧ leading
block = B): C = BN and D = N^HBN are forced either way, and a forged N
or B refuses. The producer applies its permutation P before emission –
P-conjugation is index renaming on matrix and term vector alike, so the
catalogue rule is the P = id core. Corners are structural: k = 0 gives
L = I (A = B); m = 0 forces A = 0 (empty B, no inner witness content). -/
def checkKernel (m k : Nat) (A : Fin (m + k) → Fin (m + k) → Rat)

      qlsum ((List.finRange m).map fun b =>
        kernelExt m k N a i * B a b * kernelExt m k N b j)))) &&
    (if innerT then checkTri m B Z else checkDiag m B Z))

```

## Correspondence (Steele display ↔ Lean)

**reviewer-certified against the displayed texts** The dictionary below is a reviewer-certified statement of how the mechanized statements above interpret the displayed rule: display metavariable  $\mapsto$  Lean binder, each display hypothesis  $\mapsto$  the premise or side condition carrying it, the display conclusion  $\mapsto$  the goal — with any deliberate difference in width between display and mechanization named outright. Certification is recorded as a hash triple over (the displayed cell, the extracted statement texts, this dictionary's own text); if any of the three changes, this block turns amber until a reviewer re-certifies. The correspondence claim itself remains editorial — reviewer-grade, not machine-checked; its machine-checked successor types each soundness statement against the rule as a structured object, and supersedes this block per rule as it lands.

As at PsdCERTTri — premise-free silence, the shared conclCheck row at size  $m + k$ , the same syzygyConclusionForm selector and undisplayed evaluability pack — with the witness row exchanged for the kernel-completion data:

- the block sizes  $\mapsto m\ k : \text{Nat}$  with  $A : \text{Fin } (m + k) \rightarrow \text{Fin } (m + k) \rightarrow \mathbb{Q}$  (kernel coordinates last, as displayed — the producer's permutation is applied before emission, so the certified rule is the  $P = \text{id}$  core of the roster note);  $N \mapsto N : \text{Fin } m \rightarrow \text{Fin } k \rightarrow \mathbb{Q}$ ;  $B \mapsto B$ ; the “/T-or-/DD inner witness”  $\mapsto$  the pair  $\text{innerT} : \text{Bool}$  (which inner check) and  $Z : \text{Fin } m \rightarrow \text{Fin } m \rightarrow \mathbb{Q}$  (its witness).
- the displayed factorization row  $A = L^T B L$  entrywise exactly,  $L = (I \mid N)$ , together with the inner witness  $\mapsto$  the single Boolean  $\text{hwit} : \text{PsdCert.checkKernel } m\ k\ A\ N\ B\ \text{innerT}\ Z = \text{true}$ , entering through  $\text{checkKernel\_posSemidef}$  ( $A \succcurlyeq 0$  — the trio's one genuinely  $\succcurlyeq$ -shaped member, so here the formula boundary loses nothing) and consumed as  $\text{checkKernel\_quadForm\_nonneg}$ .

Width note, beyond /T's: the checked kernel and rank content (the roster note's §1 equivalents) is consumed by the matrix-side bridge but never surfaces in the sequent — the certified formula-level claim is exactly the quadratic-form conclusion, neither more nor less, which is the honest reading the commentary states and this triple pins.

## Lean verifier receipts

module BernsteinLogic.Soundness; bound build a20d90e66c13... (bound from receipt a9c0e34d3e3c9c8c, 2026-08-03T21:30:36Z). A receipt records that named checking layers accepted a build: (module, compiled-artifact SHA-256, environment SHA-256, checker layers), minted when the checking gate ran; the store receipts attesting the bound build are listed with the layers each run credited. Nothing here asks the reader to trust the store: every layer is an independently runnable program over the quoted sources — rebuild the module and re-run the checkers to reproduce the verdict. Receipts attesting superseded builds credit no layer and are omitted from this rendering (the count of omissions, if any, is noted below).

## HOL verifier receipts

**documentary** hol-strict CLEAN: theory bern\_tr\_soundpsd, 4 theorems, 0 cheat-tagged, 0 nonstandard axioms (whitelist: DISK\_THM; the four bool axioms), 249-theory ancestry — verification run of 2026-07-22 on an isolated build host, against a content-addressed checkout of the exact sources cited here (git blob c01e0b0c...). The shared semantic spine (sound\_psdCert0f) is displayed in the /Tri section per the family-preamble convention; this corollary discharges the quadratic-form fact via the ported kernel-extension bridge (psdCheckK\_quadForm, theory bern\_psd, where the witness check itself — psdCheckK, over the extension kernelExt — is ported with kernel-EVAL receipts). The payload record and its wellformedness arm ride the ported proof-object stratum (theory bern\_tr\_catdata2, 272 theorems, 0 offences, same run).

HOL receipts are documentary: quoted results of hol-strict runs and census rows from the HOL4 development's build evidence, not minted receipt artefacts. A HOL receipt store (the Lean store's twin) is named future work.

## Proof

Genre: admissible rule (tier 2) — reduction to verified machinery. The certificate-family preamble is stated in the PSDCERTTRI section and applies verbatim. This is the *semidefinite* member: it certifies  $A \succcurlyeq 0$  together with an exactly-checked kernel, for the boundary cases the two strict tiers cannot touch.

**Recipe R30.1** (the PSDCERTKERNEL instance). Data:  $A \in \mathbb{Q}^{(m+k) \times (m+k)}$  with the  $k$  kernel coordinates *last* (the producer applies its permutation before emission — conjugation by a permutation is index renaming on matrix and term vector alike, so the identity-permutation form loses no generality);  $N \in \mathbb{Q}^{m \times k}$ ; the kernel-completion row matrix  $L := (I_m \mid N)$ ; a leading block  $B \in \mathbb{Q}^{m \times m}$  with a /T-or-/DD inner witness  $Z$ . Checked premises: the factorization  $A = L^T B L$  holds *entrywise exactly* (recomputed), and  $B$  passes the selected strict inner check. Then

$$\frac{\text{checkKernel}(A, N, B, Z) = \text{true} \quad c \equiv -\sum_{i,j} A_{ij} p_i p_j}{\Phi \vdash \Psi} \quad \text{PSDCERTKERNEL} \quad \rightsquigarrow \quad \text{discharged by sound\_psdCertKernel.}$$

The factorization check is — given the symmetry of  $B$ , which the selected inner check itself verifies — equivalent to the three separate conditions ( $A$  symmetric;  $A \cdot K = 0$  exactly for  $K = \begin{pmatrix} -N \\ I_k \end{pmatrix}$ ; leading block of  $A$  equal to  $B$ ): forward,  $B$ 's symmetry makes  $A = L^T B L$  symmetric and  $LK = 0$  kills  $AK$ ; backward,  $AK = 0$  forces the cross block  $BN$  and then the trailing block  $N^T B N$ . Either way the off-leading blocks are forced, so a forged  $N$  or  $B$  refuses.

**Proposition R30.2** (matrix warrant). If  $B \succ 0$  (hence  $\succcurlyeq 0$ ) and  $A = L^T B L$  for the rectangular  $L = (I \mid N)$ , then  $A \succcurlyeq 0$ . Moreover  $x^T A x = 0$  exactly on  $\text{span } K$ , so the certificate fixes  $\ker A = \text{span } K$  and  $\text{rank } A = m$ .

*Proof.* Positive semidefiniteness is rectangular congruence, with no invertibility anywhere:  $x^T A x = (Lx)^T B (Lx) \geq 0$  (the kernel proof is this one line, posSemidef\_of\_factor). For the kernel content, write  $x = (x_1, x_2)$  against the block split and note  $Lx = x_1 + Nx_2$ , while  $LK = -N + \bar{N} = 0$ ; with  $B \succ 0$ ,  $x^T A x = 0$  iff  $Lx = 0$  iff  $x = Kx_2$  — i.e. the zero set of the form is exactly  $\text{span } K$ . That zero set is the kernel: if  $Lx = 0$  then  $Ax = L^T B (Lx) = 0$ , and conversely  $Ax = 0$  forces  $x^T A x = 0$ , hence  $Lx = 0$ . The columns of  $K$  are independent (its lower block is  $I_k$ ), so  $\ker A = \text{span } K$  has dimension  $k$  and  $\text{rank } A = m$  by rank-nullity.  $\square$

**Remark R30.3** (exact kernels are forced, not a method limitation). A rounding-tolerant witness for kernel *directions* cannot exist for a residual-style check — one attesting the kernel claim only up to an  $\varepsilon$ -residual, with no exact kernel equation:  $\{A \succcurlyeq 0, \det A = 0\}$  is a boundary set with empty interior, so a check whose acceptance region contains an entrywise- $\varepsilon$  neighbourhood of a true instance also accepts some  $A - \varepsilon' I \not\succcurlyeq 0$ . The split is therefore forced, not preferred: exact kernel data plus a rounding-tolerant bulk (the /DD inner witness), with tolerance able to live in the bulk and nowhere else — and it matches the intended producers, whose kernels are *semantic* (a conservation law, a syzygy relation, the all-ones vector of a graph Laplacian):  $N$  comes from theorems, and floats only ever touch  $Z$ .

**Remark R30.4** (each hypothesis, and the corners). *Entrywise-exact factorization*: the whole kernel claim rides on  $AK = 0$  holding exactly; an  $\varepsilon$ -approximate factorization certifies nothing (previous remark). *The strict inner witness*:  $B \succ 0$  is what confines the zero set to  $\text{span } K$  — a merely semidefinite  $B$  would leave undeclared kernel directions inside the leading block. *Kernel coordinates last*: bookkeeping only, by the permutation argument in the recipe. Corners are structural, not special-cased:  $k = 0$  gives  $L = I$  and the rule degenerates to its inner strict tier ( $A = B$ );  $m = 0$  forces  $A = 0$  (empty  $B$ , no inner witness content — the factorization premise is the entire content).

*Remark* R30.5 (what reaches the formula layer). The checker verifies the kernel and rank content (a forged  $N$  refuses), but the formula language states only the quadratic-form conclusion  $\sum_{i,j} A_{ij} p_i p_j \geq 0$  — which for this rule is honest ( $\succ$ -shaped, per the preamble’s strictness discipline) and loses only the kernel/rank *statement*, not its checking. Making rank and kernel formula-expressible needs closed-tensor terms and a tensor-valued closed evaluator — the same named extension the PCONSTEXACT section records for exact matrix identities; short of that extension, the kernel content is certificate-level assurance surfaced here, deliberately not hand-faked into the formula grammar.

## Rule 31. ReLU-SPLIT (admissible rule)

### The rule (Steele metanotation)

as realized in the mechanized development; source row: `rules.toml` — *ReLU-Split*. The metanotation statement is typeset by hand for notational quality; its mechanized ground truth is the Lean statement below, extracted from the sources at every build of this book and hash-bound. The rule *roster* is machine-checked (every mechanized rule tag round-trips to exactly one catalogue row); the statement *text* is editorial, checked by eye against the extracted Lean beside it.

$$\frac{\Phi \wedge (h \geq 0) \vdash \Psi[b := h] \quad \Phi \wedge (h \leq 0) \vdash \Psi[b := 0] \quad \text{relu}_{\{h\} \rightarrow \{y\}} \in H \quad (y \text{ typed at rank } 0)}{\Phi \vdash \Psi} \text{ReLU-SPLIT}$$

ReLU-SPLIT is the case-split rule of the ReLU family: from two branch proofs — the goal with the output position replaced by  $h$ , under  $\Phi$  strengthened by  $h \geq 0$ ; and the goal with the output position replaced by  $0$ , under  $\Phi$  strengthened by  $h \leq 0$  — conclude the goal outright, per rank-0 node: the tensor-shaped reading of the rule is *false*, not merely unrealized (the proof section's scope remark carries the mixed-sign countermodel), so a producer splits scalar by scalar. It is the *complete*-verification move of the neural-network literature (the Reluplex and branch-and-bound lineage): where the affine envelope of LiRPA loses too much, a producer splits on the neuron's sign and pays with proof size — each split doubles the branch count, which is exactly the branch-and-bound tradeoff.

Unlike every other rule in this book so far, ReLU-SPLIT has *no certificate node*: no payload constructor, no wire tag — a certificate stream never contains one, so there is nothing for this rule's checker column to recompute. A producer elaborates it away. The elaboration's target is the *derivation* the rule abbreviates (case analysis over the sign-split fact, equality transport in each branch, and structural plumbing), whose nodes the checker checks by their own rules — a certificate fragment that becomes emittable exactly when the context-carrying case split it opens with lands as a core constructor (today that form is a satellite soundness theorem only; the proof section states the dependency). What stands unconditionally is the rule-level semantic theorem of the proof section's mechanization remark.

Each ingredient of the two premises is load-bearing for the elaboration. The branch strengthenings ( $h \geq 0$ ,  $h \leq 0$ ) are what the case fact discharges into each branch context — remove one and that branch proof has no purchase on the sign information. The substitution alignment ( $\Psi$  with the output position filled by  $h$ , respectively  $0$ ) is what the equality transport rewrites through: inside the active branch the node's fact  $y = h$  carries  $\Psi[b := h]$  to  $\Psi$ , and inside the inactive branch  $y = 0$  carries  $\Psi[b := 0]$  to  $\Psi$ .

**notes** The checker column remains empty for the structural reason: no certificate stream ever contains a ReLU-SPLIT node, so there is nothing for the checker to recompute. The rule-level statement exists: `sound_reluSplit` takes the two branch validities to the conclusion's validity, at the rank-0 scope the recipe's own per-scalar route always meant — and the companion theorem `reluSplit_rank0_necessary` mechanizes the mixed-sign countermodel showing the tensor-shaped reading is false, upgrading the family's shape-scope remark from derivation-obstruction to semantic necessity for this rule. A verified elaboration function producing the derivation does not yet exist. The derivation requires the context-carrying form of disjunction elimination — the sign-split disjunction arrives as a sub-conjunct of the premise, which the plain sequent form of  $\vee E$  cannot reach; see the  $\vee E$  section's note.

### Lean statement

The rule-level semantic lemma, at the rank-0 scope: the template  $\Psi$  is an arbitrary formula with an arbitrary marker wire for  $b$ ; the three substitution instances are hypotheses via `substituteInFormula` (EqELIM's substitution predicate); the branch strengthenings are ReLU-Pos/ReLU-Neg's premise atoms verbatim; the linkage and its extraction are the family's (LiRPA section). The second theorem is the scope's necessity witness: a shape-[2] fixture with mixed-sign input on which both branch premises are valid and the conclusion fails.

hardened (safe\_verify (hardened screen)) **current**

decorrelated (lean4export + nanoda (decorrelated kernel)) **current**

**comparator:** none no fixture in the three-implementation comparator harness (compiled / kernel-interpreted / reference-interpreted) exercises this rule.

## HOL4 statement

### NO HOL STATEMENT YET

ReLU-SPLIT has no certificate representation on either side of the seam: no payload constructor, no wire tag, no check function — a producer elaborates the rule into its derivation, so a certificate stream never contains a ReLU-SPLIT node and there is nothing for a HOL port to mirror. Any future HOL treatment would be a formalization of the rule-level statement or the derivation itself (the Lean side of the former exists — `sound_reluSplit`), not a port of checker code.

## HOL verifier receipts

### NONE

no HOL verification receipt exists for this rule.

## Proof

Genre: admissible rule (tier 2) — but of the family’s third kind. PCONSTEXACT is admissible by reduction to verified machinery; its siblings here are admissible with shipped direct lemmas; ReLU-SPLIT is admissible in the purest sense: it has *no proof-term constructor and no wire tag* — a certificate stream never contains a ReLU-SPLIT node. The derivation below is the rule’s intended elaboration, and it becomes a shippable certificate fragment exactly when the context-carrying case split it opens with becomes a core constructor (Remark R31.2); the warrant that stands on its own is the rule-level theorem: `sound_reluSplit` states the rule itself, at the rank-0 scope Remark R31.4 proves is the rule’s true extent.

**Recipe R31.1** (the ReLU-SPLIT elaboration). The rule, as the source catalogue states it:

$$\frac{\mathcal{T}_+ \triangleright \Phi \wedge (h \geq 0) \vdash \Psi[b := h] \quad \mathcal{T}_- \triangleright \Phi \wedge (h \leq 0) \vdash \Psi[b := 0]}{\Phi \vdash \Psi} \text{ReLU-SPLIT}$$

where  $b$  marks the occurrences of the output wire  $y$  of a ReLU application  $\text{relu}_{\{h\} \rightarrow \{y\}} \in H$ , so that  $\Psi = \Psi[b := y]$ . Two side conditions ride under that “where”, made explicit by the realized statement exactly as the siblings’ displays make theirs: the linkage itself (the warrant consumes the family’s port lookup), and — semantic necessity, not caution — the output wire typed at rank 0 (Remark R31.4). The intended elaboration of one such node is the derivation:

1. the node’s sign-split fact —  $(h \leq 0 \wedge y = 0) \vee (0 \leq h \wedge y = h)$ , the packaged semantic contract stated in the LIRPA section’s family template — enters as a sub-conjunct of the premise (the sp-axiom convention: for an application in  $H$ , its packaged contract is available premise-side as an axiom, true at every admissible valuation — the same convention under which the cell rules’ one-hot disjunction enters);
2.  $\vee E$  in its context-carrying form splits on it (see Remark R31.2);
3. *active branch* (context gains  $0 \leq h$  and  $y = h$ ): the branch context is aligned with  $\mathcal{T}_+$ ’s premise  $\Phi \wedge (h \geq 0)$  and consulted, in five named moves —  $\wedge E$  extracts  $\Phi$  and the case conjunct  $0 \leq h$ ; the bound node’s polarity-flip reading re-orientes the latter to  $h \geq 0$  (PBOUND, reading (G), the one-node move displayed at the ReLU-NN section’s active branch; the ReLU-ABOVE section walks the toolkit’s longer chains);  $\wedge I$  rebuilds  $\Phi \wedge (h \geq 0)$ ; CUT against  $\mathcal{T}_+$  yields  $\Psi[b := h]$  in the branch context; and EQSYM on the context’s  $y = h$  followed by EQELIM along  $h = y$  (wire-to-wire, the node’s one shared shape) transports it to  $\Psi[b := y] = \Psi$ ;
4. *inactive branch* (context gains  $h \leq 0$  and  $y = 0$ ): the same route with the mirrored atoms, four grouped moves ( $h \leq 0$  needs no reorientation, so the PBOUND step drops out);  $\mathcal{T}_-$  yields  $\Psi[b := 0]$ , and EQSYM + EQELIM along  $0 = y$  transport it to  $\Psi$ ;
5. CUT and WEAKEN stitch the case analysis back under the original  $\Phi$ .

Step 4’s transport has a rank-0 constant side, so at tensor-shaped instances it is stopped by EQELIM’s broadcast-shape gate, exactly as the family’s shape-scope remark records (Remark R22.2, ReLU-NN section) — at such instances a producer splits per scalar node (ReLU-NEG’s direct node supplies the shape-general fact  $y = 0$ , but transporting it into an arbitrary  $\Psi$  rides the same gate, so the per-scalar split is the general route — and necessarily so: Remark R31.4 proves the tensor-shaped reading admits a countermodel).

**Remark R31.2** (why the context-carrying  $\vee E$ ). The disjunction being eliminated does not stand alone as the premise: it arrives *inside* the premise conjunction, next to everything else  $\Phi$  carries. The plain sequent form of  $\vee E$  ( $\Phi_1 \vdash \Psi$  and  $\Phi_2 \vdash \Psi$  give  $\Phi_1 \vee \Phi_2 \vdash \Psi$ ) cannot reach it — and this is not a stylistic gap: the  $\vee E$  section records the countermodel showing the context-carrying form is strictly stronger than the printed one (no elaboration of the former into the latter exists). This derivation is the load-bearing consumer of that form. The form is proven sound as a satellite lemma (`sound_orEctx`), and that is currently *all* it is: it has no core constructor and no wire tag, so the derivation above is checkable as a certificate fragment only once the constructor lands — until then the rule’s standing warrant is Remark R31.3’s theorem, and the elaboration is the design the constructor exists to serve.

**Remark R31.3** (mechanization status — the rule-level statement). The checker column remains empty for the structural reason it always was: no certificate ever contains the rule, so there is no payload to validate and no soundness case in the checker’s recursion. The rule-level statement exists: `sound_reluSplit` is the semantic lemma — from the validity of the two branch sequents and the

linkage, the conclusion sequent is valid — built from exactly the vocabulary the rest of the catalogue already uses (the linkage extraction `reluLinked_facts`, the substitution predicate `substituteInFormula` that EQELIM’s payload already uses, and the semantic transport `Formula.holds_subst_congr` that EQELIM’s soundness already rides). The template  $\Psi$  with its marked occurrences  $b$  is an arbitrary formula over an arbitrary marker wire, with the three substitution instances ( $\Psi[b := h]$ ,  $\Psi[b := 0]$ ,  $\Psi = \Psi[b := y]$ ) as hypotheses — no freshness condition, since the proof transports along value equality, never syntax. “Derivable, by inspection of this recipe” is thereby backed by a theorem at every instance the recipe itself reaches (rank-0 nodes — [Remark R31.4](#)); a verified elaboration function producing Recipe [R31.1](#)’s derivation does not yet exist.

*Remark R31.4* (the rank-0 scope is semantic necessity). `sound_reluSplit` hypothesizes the output wire typed at rank 0, and this is the rule’s true extent rather than proof convenience. The family’s shape-scope remark ([Remark R22.2](#)) records that the *derivation*’s constant-sided transport is stopped by EQELIM’s broadcast-shape gate at tensor shapes; for the siblings the direct lemma is nonetheless shape-general, so the gate reads there as a technicality of the derivation route. Not here: `reluSplit_rank0_necessary` (same module) mechanizes a countermodel showing the shape-general reading of `ReLU-SPLIT` is *false*. Template  $\Psi(b) = (b = 0) \vee (b = h)$  over a shape-[2] node,  $\Phi = \top$ : both premises are valid ( $\mathcal{T}_+$  through  $h = h$ ,  $\mathcal{T}_-$  through  $0 = 0$ ), yet at the mixed-sign valuation  $h = [1, -1]$ ,  $y = [1, 0]$  neither disjunct of the conclusion holds. Mixed signs are exactly what the rule’s case analysis cannot see from sign-definite branch hypotheses — the semantic content of “each split doubles the branch count”: a tensor node is  $2^n$  scalar cases, not 2. Even shape [1] fails, by a different leak (broadcast-arity mixing): take  $\Psi(b) = (b = h) \vee (b + w \geq 0)$  with  $w$  typed at [2] and premise  $\Phi = (w \geq 0)$ . Both branch sequents are valid —  $\mathcal{T}_+$  through  $h = h$ ,  $\mathcal{T}_-$  through  $0 + w \geq 0$ , the rank-0 constant broadcasting to  $w$ ’s shape — yet at  $h = [-1]$ ,  $y = [0]$ ,  $w = [1, 1]$  the conclusion fails:  $y = h$  fails entrywise, and the [1]-shaped  $y + w$  atom is unsatisfiable outright by the strict-shape arithmetic, which broadcasts rank-0 sides only (this leak is stated as prose beside the mechanized [2] witness, not itself mechanized). The recipe’s step-4 note (“the per-scalar split is the general route”) is thus not a workaround for a gate but the only sound reading; producers split per rank-0 node, and `sound_reluSplit` is the rule those splits instantiate.

*Remark R31.5* (when a producer splits). Splitting is the *complete*-verification move of the neural-network literature — Reluplex’s case analysis [134], systematized as branch and bound [33]: exact where LiRPA’s envelope is lossy, at the price of one branch doubling per split neuron, so proof size is exponential in the split count. The practical frontier — which neurons to split, which to relax — is the branch-and-bound literature’s whole subject; the calculus prices the choice honestly (a split is two subtrees, an envelope is one node) and takes no position on it.

## 15.4 Assume–Guarantee Composition

### Rule 32. PROMISE (admissible rule)

#### The rule (Steele metanotation)

as realized in the mechanized development; source row: `rules.toml` — *Promise*. The metanotation statement is typeset by hand for notational quality; its mechanized ground truth is the Lean statement below, extracted from the sources at every build of this book and hash-bound. The rule *roster* is machine-checked (every mechanized rule tag round-trips to exactly one catalogue row); the statement *text* is editorial, checked by eye against the extracted Lean beside it.

$$\frac{\Phi_1 \vdash Q \quad \Phi_2 \wedge Q \vdash \Psi \quad \text{wires}(Q) \subseteq Y \quad \text{wires}(\Phi_1) \cap (\text{wires}(\Phi_2) \cup \text{wires}(\Psi)) \subseteq Y}{\Phi_1 \wedge \Phi_2 \vdash \Psi} \text{PROMISE}$$

$Y$  = the declared interface (payload wire list; bundle entries addressed as  $\text{TIdx}(w, i)$ ). The two confinement checks are the locality warrant, not soundness needs: the contract  $Q$  is the *datasheet* — the public artefact whose vocabulary is the separator algebra — and the cost identities (LP size, ZK disclosure set) quantify over certificates carrying these checks.

a Bernstein Logic rule outright: the baked base theory lists it in its core roster (grouped there under an assume–guarantee comment), the certified checker decodes its wire node, and its certificate relations ride the pin table — there is no intermediate composition logic between this rule and the base calculus. The tier word above classifies proof theory (the unpack is **WEAKEN** +  $\wedge$ -restructuring + **CUT**); core-roster membership is wire placement.

**PROMISE** is the calculus's acyclic composition rule: it discharges an assumption one component makes about another. The supplier proves the contract  $Q$  from its own premises ( $\Phi_1 \vdash Q$ ); the consumer proves the goal *using*  $Q$  ( $\Phi_2 \wedge Q \vdash \Psi$ ); the composite concludes  $\Phi_1 \wedge \Phi_2 \vdash \Psi$  with the contract discharged internally — cut, wearing interface bookkeeping. A producer reaches for it wherever a system decomposes along a directed interface: certify the downstream component against a *datasheet* (the contract, written over the declared interface wires only), certify the upstream component as meeting the datasheet, and compose without ever re-deriving either side inside the other.

What the checker recomputes: the splice plumbing and the locality warrant. The plumbing — the contract sits at a payload-declared conjunct path in the consumer's premise; the composite premise is the consumer's with the contract replaced by the supplier's premise at that path — is verified by exact read/replace on the conjunction tree. The locality warrant is two wire-confinement checks: the contract's free wires lie inside the declared interface, and the supplier's wires meet the consumer's and the goal's only inside it.

The hypotheses split by role, and the split is the rule's point. Soundness consumes only the plumbing: drop the path checks and the “composite” premise could be unrelated to the two sub-proofs. The confinement checks are *warrant, not soundness* — cut is sound regardless — but dropping them destroys the datasheet reading: a contract mentioning supplier-private wires is no longer a public interface artefact, and every quantitative consequence hung on the interface (certificate size scaling with the separator rather than the components, bounded disclosure of component internals) quantifies over certificates that carry these checks. The proof section separates the two roles explicitly.

**notes** Tier reading: proof-theoretically the rule is admissible — one node unpacks into **CUT** against premise-transported copies of the cited sub-derivations, a global rewrite of those sub-proofs rather than a local chain (the proof section's recipe walks why: **WEAKEN** and **CUT** are head-positional) — while in the realized calculus it is a native constructor, kept for cost and for the locality-warrant payload. The tier column records the proof-theoretic status; constructor membership is wire placement.

## Correspondence (Steele display $\leftrightarrow$ Lean)

**reviewer-certified against the displayed texts** The dictionary below is a reviewer-certified statement of how the mechanized statements above interpret the displayed rule: display metavariable  $\mapsto$  Lean binder, each display hypothesis  $\mapsto$  the premise or side condition carrying it, the display conclusion  $\mapsto$  the goal — with any deliberate difference in width between display and mechanization named outright. Certification is recorded as a hash triple over (the displayed cell, the extracted statement texts, this dictionary's own text); if any of the three changes, this block turns amber until a reviewer re-certifies. The correspondence claim itself remains editorial — reviewer-grade, not machine-checked; its machine-checked successor types each soundness statement against the rule as a structured object, and supersedes this block per rule as it lands.

Judgment frame as in Ax; the statement bundles its data as PromiseStep (field-for-field the payload minus the two sub-proofs, which enter as ihs/ihc).

- $\Phi_1 \vdash Q \mapsto \text{ihs}$  with  $\text{supplierPost} : \text{supplier.post} = \text{contract}; Q \mapsto \text{contract} : \text{Formula}; \Phi_1 \mapsto \text{supplier.pre}$ .
- $\Phi_2 \wedge Q \vdash \Psi \mapsto \text{ihc}$ , with the certified statement taking the path-general form:  $Q$  sits at a *payload-declared conjunct path* ( $\text{pathReads} : \text{consumer.pre.conjGet? path} = \text{some contract}$ ), not at a fixed position — the  $\text{ctx-}\forall E$  style.  $\Phi_2 \mapsto \text{ctx}$ , the consumer premise with the contract deleted at the path ( $\text{ctxReads}$ ).
- conclusion  $\Phi_1 \wedge \Phi_2 \vdash \Psi \mapsto$  the goal for  $\text{st.seq}$ , whose premise is pinned by  $\text{prePlumb}$ : the consumer's premise with the supplier's premise spliced in *at the same path* where  $Q$  sat. Order honesty: at the displayed root-right instance ( $Q$  the right conjunct of  $\Phi_2 \wedge Q$ ), the splice therefore pins  $\text{seq.pre}$  to  $\Phi_2 \wedge \Phi_1$  — the displayed  $\Phi_1 \wedge \Phi_2$  is obtained by semantic conjunction commutativity, not by direct instantiation. Path generality remains strictly wider than the display, in the safe direction; the conjunct *order* is the one representational difference, named here.  $\text{postEq}$  carries  $\Psi$  across unchanged.
- the two confinement premises ( $\text{wires}(Q) \subseteq Y$ ; the interface-separation check)  $\mapsto$  the Step fields  $\text{contractConfined}$  and  $\text{separation over iface} \mapsto Y$  — carried, checked, and consumed by *no* step of  $\text{sound\_promise}$ : the displayed caption's claim that they are the locality warrant rather than soundness needs is visible in the statement itself: the proof never touches them, as on the QTSL pages.

Width note: beyond the deliberate path-generality and the conclusion-order transposition named above (the splice yields  $\Phi_2 \wedge \Phi_1$ ; the display's order needs conjunction commutativity, semantically free), neither side is wider; the soundness content is pure predicate-logic cut over the semantics, exactly as the witness column says.

## Lean verifier receipts

module BernsteinLogic.Soundness; bound build a20d90e66c13... (bound from receipt a9c0e34d3e3c9c8c, 2026-08-03T21:30:36Z). A receipt records that named checking layers accepted a build: (module, compiled-artifact SHA-256, environment SHA-256, checker layers), minted when the checking gate ran; the store receipts attesting the bound build are listed with the layers each run credited. Nothing here asks the reader to trust the store: every layer is an independently runnable program over the quoted sources — rebuild the module and re-run the checkers to reproduce the verdict. Receipts attesting superseded builds credit no layer and are omitted from this rendering (the count of omissions, if any, is noted below).

```

## HOL verifier receipts

**documentary** Documentary citations. Family validation: `bern_fam_resid` built GREEN with all ten `famEq` arms validated, `hol-strict` clean; spine census: `bern_joins` GREEN under `hol-strict` (55 theorems, 0 offences, 208-theory ancestry including this theory), `checkJoins_eq_checkPf` verified verbatim in the built signature. The cited `famEq` lemma is the kernel-checked per-node equivalence: under well-formed columns (`wfColumns/mkCtx/nodeCorr`) at this rule's wire tag, the columnar family check coincides with the flat reference walk's arm for this rule. There is no signed HOL receipt store yet — these citations are documentary. Semantic stratum, also ported: the soundness twin `sound_promise` (theory `bern_tr_b14: hol-strict` clean, 2 theorems, 0 offences, verification run of 2026-07-22 on an isolated build host, content-addressed at the same sources), consumed by the certified-fragment keystone (`checkPf_sound_frag`, theory `bern_tr_splice`, 20 theorems, 0 offences, same run): a reference-checker accept inside the proven wire fragment yields sequent validity.

HOL receipts are documentary: quoted results of `hol-strict` runs and census rows from the HOL4 development's build evidence, not minted receipt artefacts. A HOL receipt store (the Lean store's twin) is named future work.

## Proof

Genre: admissible rule (tier 2) — a proof-tree-rewriting recipe. Proof-theoretically `PROMISE` unpacks into core rules (conjunct plumbing + `CUT`); in the realized calculus it is a native constructor, kept for cost and for the locality-warrant payload. The recipe shows the unpack; the semantic warrant is the kernel lemma `sound_promise`, which is the unpack's semantic shadow run in one pass.

**Setting.** The payload (the `PromiseStep` structure quoted above) carries a supplier sequent  $\Phi_1 \vdash Q$ , a consumer sequent whose premise contains the contract  $Q$  at a declared conjunct path  $\pi$  (write it  $\Phi_2 \wedge_\pi Q \vdash \Psi$  — the  $\pi$ -notation meaning  $Q$  sits at path  $\pi$  in the premise's conjunction tree,  $\Phi_2$  being the rest), a declared interface wire list  $Y$ , and the composite sequent, whose premise is the consumer's with  $Q$  replaced by  $\Phi_1$  at  $\pi$  and whose conclusion is  $\Psi$ . Four checked hypotheses: (P1) the path reads  $Q$  in the consumer's premise; (P2) replacing  $Q$  by  $\Phi_1$  at  $\pi$  yields exactly the composite premise; (P3)  $\text{wires}(Q) \subseteq Y$ ; (P4) the supplier's wires meet the consumer's and the goal's only inside  $Y$ . (P1)–(P2) are the splice plumbing; (P3)–(P4) are the locality warrant.

**Recipe R32.1** (the `PROMISE` instance — cut through a conjunct path). The general admissible template (one rule node  $\rightsquigarrow$  a derivation fragment over core rules with the same conclusion, applied leaf-first until no such node remains) instantiates as:

$$\frac{\mathcal{T}_s \triangleright \Phi_1 \vdash Q \quad \mathcal{T}_c \triangleright \Phi_2 \wedge_\pi Q \vdash \Psi}{\Phi_2 \wedge_\pi \Phi_1 \vdash \Psi} \text{PROMISE} \rightsquigarrow \frac{\frac{\mathcal{T}_s}{\Phi_2 \wedge_\pi \Phi_1 \vdash Q} \quad \frac{\mathcal{T}_c}{\Phi_2 \wedge_\pi Q \vdash \Psi}}{\Phi_2 \wedge_\pi \Phi_1 \vdash \Psi} \text{CUT}$$

where, writing  $C$  for the composite premise  $\Phi_2 \wedge_\pi \Phi_1$ : the left branch derives  $C \vdash Q$  by `CUT` from  $C \vdash \Phi_1$  (an `Ax` leaf  $C \vdash C$ , then a conclusion-side  $\wedge E$  chain along  $\pi$ ) against a *premise-transported* copy of  $\mathcal{T}_s$ , and `CUT`'s right premise proper is  $C \wedge Q \vdash \Psi$ , a *premise-transported* copy of  $\mathcal{T}_c$  — the display elides both transports. Premise transport (re-rooting a derivation  $X \vdash \Psi$  at a premise  $Y$  whose addressed conjuncts entail  $X$ ) is *not* a local chain in this calculus: `WEAKEN` and `CUT` are deliberately head-positional — each grafts one conjunct at the premise root's right — so the premises reachable from an opaque sub-proof  $X \vdash \Psi$  by insertion alone are exactly  $X$  with right-appended conjuncts (`CUT` can also *consume* an already-present root-right conjunct when a proof of it is supplied — removal, never interior insertion or permutation), and even  $Y \wedge X \vdash \Psi$  is locally out of reach. The transport is instead an induction over the sub-derivation itself; its principal cases: rules that copy their premise tree verbatim from their sub-proofs re-instantiate on the transported children; premise-free leaves conclude at an arbitrary premise by the `NORM` convention (an `Ax` leaf  $\Phi \vdash \Phi$  re-derives at  $Y$  as  $Y \vdash Y$  plus a conclusion-side  $\wedge E/\wedge I$  rebuild); and the two head-positional rules are their own inductive cases, because re-rooting commutes with the head graft: a transported `WEAKEN` grafts its conjunct onto the new root, and a transported `CUT`'s right premise re-forms as the new root with the cut formula appended. This list is not exhaustive over the catalogue: the *premise-forming* rules ( $\vee E$ 's conclusion premise is the disjunction of its branch premises; `SUBDIVIDE`'s branch premises conjoin the region data) and the context-carrying rules (`PROMISE`, `SZYGY`, whose path plumbing must compose with the splice — the  $\vee E$  section's machinery) are neither verbatim copies nor leaves; each needs its own commutation case, and those cases belong to the same transport metatheorem flagged as unmechanized below. Rewriting the premise field node by node under that case analysis yields the transported copies of  $\mathcal{T}_s$  and  $\mathcal{T}_c$ . Elimination costs the sizes of  $\mathcal{T}_s$  and  $\mathcal{T}_c$  plus the  $\wedge E$  chain along  $\pi$  at the auxiliary derivation plus the per-leaf `Ax` rebuilds — and each transported leaf pays its own conclusion-side rebuild chain (the proof-object grammar has no sharing), so the total is bounded by the certificate sizes plus the number of transported leaves times the addressing depth, linear in the certificate data only when that depth is bounded — and consumes `Ax` leaves throughout; conservativity holds with no new kernel semantic content, but as a global rewrite warranted by the transport induction (stated here as prose — the transport metatheorem is not yet mechanized), not as insertion of a constant-size fragment.

**Proposition R32.2** (semantic warrant). *If the supplier and consumer sequents are semantically valid and (P1)–(P2) hold, the composite sequent is semantically valid.*

*Proof.* Fix an admissible valuation  $\sigma$  satisfying the composite premise. Reading the composite premise at  $\pi$  returns  $\Phi_1$ : (P1) says  $\pi$  addresses  $Q$  in the consumer’s premise, so the replacement (P2) performs succeeded at  $\pi$ , and the read of a successful replacement returns the replacement (the round-trip lemma `Formula.conjGet_of_conjReplace`); an addressed conjunct of a holding conjunction holds (`Formula.holds_of_conjGet`); so  $\sigma \models \Phi_1$ , and supplier validity gives  $\sigma \models Q$ . Replacing  $\Phi_1$  back by  $Q$  at  $\pi$  recovers the consumer’s premise exactly (`Formula.conjReplace_back`, using (P1)–(P2)), and replacing the addressed conjunct of a holding conjunction by a formula that itself holds at  $\sigma$  preserves holding (`Formula.holds_conjReplace`, applied at  $\pi$  with  $Q$  for  $\Phi_1$ ); so  $\sigma \models \Phi_2 \wedge_\pi Q$ , and consumer validity gives  $\sigma \models \Psi$ . This is `sound_promise` verbatim: pure predicate logic over the semantics — admissibility of  $\sigma$  is passed through untouched, and neither confinement hypothesis is consulted.  $\square$

*Remark R32.3* (the confinement premises are warrant, not soundness). (P3)–(P4) appear in no step of Proposition R32.2, and dropping them alone — (P1)–(P2) retained — admits no false sequent: cut is sound regardless of where the contract’s wires live. What their removal *does* admit is a degenerate reading of the rule — a “contract” mentioning supplier–private wires, i.e. a composition whose interface is as wide as the components themselves. Everything the rule is *for* then fails: the contract stops being a datasheet (a public artefact whose vocabulary is the declared separator), certificate size stops scaling with the interface, and any bounded-disclosure reading of “what the consumer learns about the supplier” becomes vacuous. Those consequences are theorems proved elsewhere, *about certificates that carry the checks* — they quantify over exactly the certificates these hypotheses admit — which is why the checks are checked — a hypothesis whose necessity is economic and epistemic rather than semantic is exactly the kind a recipe must label, or the next reader deletes it as redundant.

*Remark R32.4* (relation to the literature). Assume–guarantee composition descends from composing-specifications calculi [2]; the subtlety those calculi negotiate is *circularity* — each component assuming what the other guarantees — which needs an induction over time or a fixpoint argument [177]. PROMISE deliberately takes the acyclic case, where plain cut suffices and the whole rule is bookkeeping around it; the circular case enters this calculus through the feedback rules — `SMALLGAIN` and `SMALLGAINN` at the sequent layer and the feedback cells of the satisfaction-layer composition rule, where the guarded-fixpoint structure is explicit, and `QWIRECOMPOSEMARKS` for liveness marks, where cyclic wiring needs no well-foundedness device at all and the wiring condition is a feasibility walk (schedules and pinned values must close around cycles) rather than a causality walk. Separating the cases — cut where cut suffices, guarded fixpoints where feedback threatens a safety face, a schedule walk where a cycle only has to deliver a mark — is the design’s answer to the classical observation that *unguarded* circular assume–guarantee reasoning about safety is unsound — there, some well-foundedness device is required.

| proof step                                                                                                                                                                               | formal anchor                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

## Rule 33. SYZYGY (core rule)

### The rule (Steele metanotation)

as realized in the mechanized development; source row: `rules.toml` — `Syzygy`. The metanotation statement is typeset by hand for notational quality; its mechanized ground truth is the Lean statement below, extracted from the sources at every build of this book and hash-bound. The rule *roster* is machine-checked (every mechanized rule tag round-trips to exactly one catalogue row); the statement *text* is editorial, checked by eye against the extracted Lean beside it.

$$\frac{\begin{array}{c} \{\Phi_i \vdash e_i \leq 0\}_{i=1}^n \quad \{g_k = 0\}_k \text{ equality sub-conjuncts of } \Phi \text{ in wire variables} \quad \lambda_i \in \mathbb{Q}_{\geq 0} \quad \nu_k \in \mathbb{Q} \\ c \equiv \sum_i \lambda_i e_i + \sum_k \nu_k g_k \text{ (exact canonical polynomial)} \quad \Psi \in \{c \leq 0, \ e \geq 0 \text{ where } c = -e, \ l \leq r \text{ where } c = l - r\} \end{array}}{\Phi \vdash \Psi} \text{ SYZYGY}$$

$\Phi \supseteq$  each  $\Phi_i$  conjunct-wise (checked); the  $\nu_k$  are free-sign exactly as FARKAS frees  $\lambda_j$  on = atoms.

free-sign  $\nu_k$  is Lemma A's CommRing sign-blindness, one theorem for both dialects. Lifts FARKAS in exactly two ways: atoms from sub-*proofs* (not sub-conjuncts), atoms of arbitrary polynomial degree. The conclusion is exposed in any of the three `syzygyConclusionForm` readings — one exact  $\mathbb{Q}$  identity under a sign flip; the transport is the ge-bridge ring lemma, applied once inside `sound_syzygy`. A Bernstein Logic rule outright: the baked base theory lists it core (its wire node decoded by the certified checker, its combination relation pinned); “assume-guarantee” names its purpose, not a separate layer.

SYZYGY is the calculus's composition rule: it combines already-proven component bounds into a bound on a weighted sum. Each component sequent  $\Phi_i \vdash e_i \leq 0$  is a sub-proof — typically “this subsystem dissipates its storage function” — and the composite premise  $\Phi$  carries, among its conjuncts, *equality atoms*  $g_k = 0$  describing how the subsystems are wired together (power-preserving interconnection: what one port supplies, another consumes). A producer reaches for the rule wherever a system-level argument says “add the component certificates with weights  $\lambda_i$  and let the internal supplies cancel”: the weights are found by whatever method the producer likes (an LP, typically), and only the resulting exact identity ships in the certificate.

What the checker recomputes, given the payload (combination term, component list, conclusion term): that every entry weight is  $\geq 0$  — premise *equality atoms* expose both polarities to the matcher, so a free-sign multiplier on an equality is realized as a nonnegative weight on the appropriate polarity, and that freedom is what makes them syzygies; that every entry of the combination really is a component conclusion or a premise equality sub-conjunct, matched by exact canonical polynomial; and that the weighted sum of those polynomials is *identically* the conclusion polynomial as canonical forms over  $\mathbb{Q}$  — coefficient-for-coefficient equality, not evaluation at test points. It further checks the bookkeeping hypotheses: each component's premise is contained conjunct-wise in  $\Phi$  (`preContains`), the conclusion term has a determinate finite shape (`conclShape`, `conclFin`), and every wire in sight has positive size (`wiresPos`, `compPostWiresPos`).

Each hypothesis is load-bearing. Drop the sign condition on the inequality weights and a producer could multiply a bound by  $-1$  and conclude its negation. Drop the entry-sourcing check and the “combination” could smuggle in atoms nobody proved. Drop the exact-identity check and the conclusion would be unrelated to the premises. Drop premise containment and a component proved over its own operating box could be applied outside it. Drop the positive-size conditions and a component conclusion over a zero-size wire — vacuously true, since it quantifies over no tensor entries — could enter the combination with full algebraic weight and push the composite to a falsehood. The proof section walks these in order.

**notes** Port-Hamiltonian reading: with  $e_i = \mathcal{L}_i V_i - s_i^{\text{ext}} - s_i^{\text{int}}$ , the equality atoms  $g_k = 0$  cancel the internal supplies and the conclusion is a dissipation inequality for  $\sum_i \lambda_i V_i$  — Tellegen's theorem in certificate form. The free-body diagram is the junction tree; internal forces at the cuts are the separator algebra.

### Lean statement

BernsteinLogic.Soundness . SyzygyStep

statement bound

```
-- Applicability data of the Syzygy rule over a hypernet — field-for-field
the reference checker's obligations, and field-for-field `PSyzygyData`
minus the component-proof list (validity hypotheses of `sound_syzygy`)
and `denBoundLog2` (the Q7 family; zero proof-theoretic weight in v1).
B13-shaped conclusion fields and B14 (`wiresPos`) are inherited verbatim
from `PFarkasData`; `compPostWiresPos` is the honest EXTENSION of B14 to
component-conclusion wires (Composition.lean header: without it a
vacuously-held component conclusion over a zero-size wire poisons the
combination — counterexample kernel-checkable). -/
structure SyzygyStep (H : Hypernet) where
  seq : Sequent
  components : List Sequent
  combination : Term
```

```

conclusion : Term

```

BernsteinLogic.Soundness . **holds\_of\_syzygyConclusionForm**

statement bound

```

/-- The ge-bridge ring lemma (the both-polarity core change): every
reading admitted by
`szyzygyConclusionForm conclusion` holds whenever the zero-normal atom
`conclusion ≤ 0` holds – the readings are the same exact  $\mathbb{Q}$  identity
re-presented under a sign flip. The zero-form is the identity transport,
the ge-polarity flip is ` $-e ≤ 0 \rightarrow e ≥ 0$ `, and the literal atom is
`l - r ≤ 0 → l ≤ r` (ArithAtom's tensor-general sub-zero bridge).
Applied once inside `sound_syzygy`, so PSyzygy (tier-1), PBound's
compact spelling (tier-3), and any future  $≤ 0$ -shaped fact rule inherit
all readings with no separate polarity justification. -/
theorem holds_of_syzygyConclusionForm {H : Hypernet} {σ : H.Valuation}
  {conclusion : Term} {F : Formula}
  (hle : Formula.holds σ (.atom .le conclusion (.const 0)))
  (hform : syzygyConclusionForm conclusion F) :
  Formula.holds σ F

```

BernsteinLogic.Soundness . **sound\_syzygy**

statement bound

```

/-- Soundness of Syzygy (= Lemma B, dialect D): valid components give a
valid composite. The argument is `sound_farkas`'s, with the per-entry
source discharge generalized: a component-sourced entry's atom holds by
component validity (through `premiseContains`), a wiring-sourced entry's
atom holds as a premise sub-conjunct; either way
`atomLeZeroPolys_sound_entryC` delivers per-entry nonpositivity at every
clamped per-entry valuation, and the nonnegative fold closes. The
zero-normal bound then reaches `seq.post` through whichever
`szyzygyConclusionForm` reading the payload declared (both-polarity core
change, 2026-07-18). -/
theorem sound_syzygy {H : Hypernet} (st : SyzygyStep H)
  (hcomps : ∀ c ∈ st.components, c.semanticallyValid H) :
  st.seq.semanticallyValid H

```

BernsteinLogic.Soundness . **atomLeZeroPolys\_sound\_entryC**

statement bound

```

/-- Every ` $(e ≤ 0)$ `-normal-form polynomial a held atom entails evaluates
nonpositively at EVERY clamped per-entry valuation, given positive-size
wire types (general shapes – heterogeneous atoms read through the
clamp; the positivity is PROPOSED-B14's honest content: zero-size atoms
hold vacuously and entail nothing). -/
theorem atomLeZeroPolys_sound_entryC {H : Hypernet} (σ : H.Valuation)
  {F : Formula} (hF : Formula.holds σ F)
  (hw : ∀ w ∈ F.freeWires, ∃ τ, H.wireType w = some τ ∧
    0 < Shape.totalSize τ.shape)
  (hix : F.atomSidesIdxFree = true) (i : ℕ) :
  ∀ pa ∈ atomLeZeroPolys F, QArith.Poly.eval (σ.entryValC i) pa ≤ 0

```

BernsteinLogic.Soundness . **wire\_discipline\_of\_bshape\_fin**

statement bound

```

/-- The PROPOSED-B13 field pair (`bshape` + `finWires`) yields the wire
discipline that per-entry evaluation consumes: every free wire reads a
finite tensor of shape `[]` or `s`. -/
theorem wire_discipline_of_bshape_fin {H : Hypernet} (σ : H.Valuation)
  {t : Term} {s : Shape} (hb : t.bshape H = some s)

```

```
(hf : t.finWires H) (hix : t.idxFree = true) :
  ∀ w ∈ t.freeWires, ∃ qw, σ.wireQ w = some qw ∧
    (qw.shape = [] ∨ qw.shape = s)
```

BernsteinLogic.Soundness . Term.evalQ\_total\_singleton

statement bound

```
/-- Total singleton evaluation: if every free wire reads as a finite
singleton tensor, the term evaluates to a singleton tensor whose scalar
is the polynomial evaluation at the valuation read-out. (Definedness half
of the PROPOSED-B13 Farkas fields, and the workhorse behind every scalar
extraction below.) -/
theorem Term.evalQ_total_singleton {H : Hypernet} (σ : H.Valuation) :
  ∀ (t : Term),
    (∀ w ∈ t.freeWires, ∃ qw, σ.wireQ w = some qw ∧ SingletonShape qw.shape) →
    t.idxFree = true →
    ∃ q, Term.evalQ σ t = some q ∧ SingletonShape q.shape ∧
      q.scalar = QArith.Poly.eval σ.rho t.toPoly
```

**What `syzygyCombinationValid` means — and what it does not.** The rule's side condition appears in the payload structure above as a single opaque name, so this book binds its meaning by displaying the definition chain in full, from the checker sources. Reading the chain: `syzygyCombinationValid` is precisely the proposition “`syzygyCheck` returns true”, and `syzygyCheck` is the disjunction of three branches of one algorithm (a branch for index-free terms, a wire-coordinate branch for indexed terms, and a mixed tagged-union branch for heterogeneous combinations of both kinds). All three branches do the same three things: decode the combination term into weighted entries (`farkasEntries` — a fixed canonical encoding, anything else is rejected); require each weight nonnegative and each entry's polynomial to occur among the  $(\cdot \leq 0)$ -normal polynomials of a *component conclusion* or of an *equality sub-conjunct of the premise* (`atomLeZeroPolys` — note that equality atoms contribute both polarities, which is exactly the free-sign multiplier discipline); and require the weighted fold of those polynomials to equal the conclusion term's canonical polynomial.

What a skeptical reader should confirm by eye in the definitions below: the conclusion term enters the check *only* as the target of the exact-identity comparison (and through a syntactic index-freedom gate); the step's posted formula `seq.post` does not appear in the check at all; and nothing in the chain evaluates, assumes, or otherwise consults the *truth* of the conclusion — the check manipulates polynomials, never valuations, so it could not covertly “assert the conclusion is true”. `seq.post` connects to the conclusion term only through the separate, purely syntactic field `postForm` — the three readings of  $c \leq 0$  enumerated by `syzygyConclusionForm` below — whose semantic transport is the separately proven ring lemma `holds_of_syzygyConclusionForm` quoted above. Semantic truth is established only in `sound_syzygy`, from the component-validity hypotheses.

BernsteinLogic.Core.Catalogue . syzygyConclusionForm

## Correspondence (Steele display ↔ Lean)

**reviewer-certified against the displayed texts** The dictionary below is a reviewer-certified statement of how the mechanized statements above interpret the displayed rule: display metavariable  $\mapsto$  Lean binder, each display hypothesis  $\mapsto$  the premise or side condition carrying it, the display conclusion  $\mapsto$  the goal — with any deliberate difference in width between display and mechanization named outright. Certification is recorded as a hash triple over (the displayed cell, the extracted statement texts, this dictionary's own text); if any of the three changes, this block turns amber until a reviewer re-certifies. The correspondence claim itself remains editorial — reviewer-grade, not machine-checked; its machine-checked successor types each soundness statement against the rule as a structured object, and supersedes this block per rule as it lands.

Judgment frame as in Ax. The statement bundles its data as **SyzygyStep** — field-for-field the reference checker's obligations, and field-for-field the payload minus the component-proof list (which enters `sound_syzygy` as the validity hypothesis `hcomps`) and minus the denominator-bound declaration (resource accounting; zero proof-theoretic weight, so rightly absent from the soundness statement).

- the component judgments  $\{\Phi_i \vdash e_i \leq 0\}_{i=1}^n \mapsto \text{st.components} : \text{List Sequent}$  with `hcomps`; the atoms  $e_i \leq 0$  have no binders of their own — each combination entry tagged `FROM-COMPONENT` is checked against a component's conclusion inside the combination check, which is where the  $e_i$  live.
- $\Phi \supseteq \Phi_i$  conjunct-wise  $\mapsto \text{st.preContains} : \text{premiseContains seq.pre c.pre}$ , per component.
- the equality sub-conjuncts  $\{g_k = 0\}$  of  $\Phi \mapsto$  the `FROM-WIRING` entry tag: such an entry's atom is checked to be a sub-conjunct of `seq.pre` directly.
- $\lambda_i \in \mathbb{Q}_{\geq 0}, \nu_k \in \mathbb{Q}$ , and  $c \equiv \sum_i \lambda_i e_i + \sum_k \nu_k g_k \mapsto \text{st.combination}$  and `st.conclusion` under `st.valid : syzygyCombinationValid` — the canonical-polynomial identity is recomputed by one of *three* certified routes (the idx-free `syzygyCheckCore` replay, the wire-coordinate `syzygyCheckW`, and the mixed `syzygyCheckM`), each discharged separately in `sound_syzygy`.
- the evaluability and positive-size packs  $\mapsto \text{conclShape}, \text{conclFin}, \text{wiresPos}, \text{compPostWiresPos}$  — displayed inline at `PBOUND`'s cell (this page's cell leaves them to the caption); `compPostWiresPos` is the honest extension of the positive-size discipline to component conclusions, whose absence has a kernel-checkable vacuous-conclusion counterexample (the source docstring).
- $\Psi$ 's three readings  $\mapsto \text{st.postForm} : \text{syzygyConclusionForm}$ , literally the displayed three-membered disjunction; the transport of the zero-normal bound to every reading is the certified-alongside `ge-bridge lemma holds_of_syzygyConclusionForm`, applied once here, inherited by `PBOUND` and the `PSDCERT` trio.

Width note: nothing in the statement consumes the port-Hamiltonian reading — supply rates, storage functions, and the wiring identity are producer-side interpretations of which the certified content is exactly the polynomial identity and its component sourcing; and the statement is proven at every hypernet and component list, with every hypothesis consumed.

## Lean verifier receipts

module BernsteinLogic.Soundness; bound build a20d90e66c13... (bound from receipt a9c0e34d3e3c9c8c, 2026-08-03T21:30:36Z). A receipt records that named checking layers accepted a build: (module, compiled-artifact SHA-256, environment SHA-256, checker layers), minted when the checking gate ran; the store receipts attesting the bound build are listed with the layers each run credited. Nothing here asks the reader to trust the store: every layer is an independently runnable program over the quoted sources — rebuild the module and re-run the checkers to reproduce the verdict. Receipts attesting superseded builds credit no layer and are omitted from this rendering (the count of omissions, if any, is noted below).

## HOL verifier receipts

**documentary** hol-strict CLEAN over the ported checker chain: theory bern\_catalogue, 472 theorems, 0 cheat-tagged, 0 nonstandard axioms (whitelist: DISK\_THM; the four bool axioms) — verification run of 2026-07-22 on an isolated build host, scripts sha-matched verbatim to the sources cited here (git blob e41b9ed0...). Downstream, the same chain carries the checker to a CakeML binary with the machine\_code\_sound tag ([ "DISK\_THM", [] ] (theory bernCertProofARM8)). Family-level bridge lemmas for the SYZYGY node (famEq\_syz, bern\_fam\_syz) ride an in-flight assembly and are not yet in the census table. As on the FARKAS and PBOUND pages: the Lean check has since grown a third (mixed tagged-union) branch, added 2026-07-19 after this port run — the divergence is refusal-direction only, and its port is named residue. Semantic stratum, also ported: the soundness twins sound\_syzygy (the proof-object form) and sound\_pBound (theory bern\_tr\_soundsyz: hol-strict clean, 7 theorems, 0 offences, verification run of 2026-07-22 on an isolated build host, content-addressed at the same sources); the certified-fragment keystone (checkPf\_sound\_frag, theory bern\_tr\_splice, 20 theorems, 0 offences, same run) discharges this rule's wire arm through the latter.

HOL receipts are documentary: quoted results of hol-strict runs and census rows from the HOL4 development's build evidence, not minted receipt artefacts. A HOL receipt store (the Lean store's twin) is named future work.

## Proof

Genre: core rule (tier 1) — an ordinary mathematical proof at Putnam-exam-solution detail. Every hypothesis of the rule is used below and remarked on; the formal-anchor table maps each step to the Lean declaration that carries it.

**Setting and claim.** Fix a hypernet  $H$ . A *valuation*  $\sigma$  assigns each wire a rational tensor of its declared shape; a sequent  $\Phi \vdash \Psi$  is *semantically valid* when every admissible  $\sigma$  satisfying  $\Phi$  satisfies  $\Psi$ . Atoms  $e \leq 0$  over tensor-shaped terms hold per-entry: every entry of the evaluated tensor is  $\leq 0$ . The rule's data (the SyzygyStep payload quoted above) supplies component sequents  $\Phi_i \vdash e_i \leq 0$  for  $i = 1, \dots, n$ , a combination certificate with weights  $\lambda_i \in \mathbb{Q}_{\geq 0}$  on the components and free weights  $\nu_k \in \mathbb{Q}$  on equality sub-conjuncts  $g_k = 0$  of  $\Phi$ , a conclusion term  $c$ , and a checked *syntactic* identity

$$c \equiv \sum_i \lambda_i e_i + \sum_k \nu_k g_k \quad (\text{equality of exact canonical polynomials over } \mathbb{Q}). \quad (*)$$

The claim (sound\_syzygy): if every component sequent is semantically valid, the composite sequent  $\Phi \vdash \Psi$  is semantically valid, where  $\Psi$  is any reading of  $c \leq 0$  admitted by syzygyConclusionForm (Lemma R33.3).

**Lemma R33.1** (nonnegative combination). *In an ordered field, if  $a_i \leq 0$  and  $\lambda_i \geq 0$  for  $i = 1, \dots, n$ , and  $b_k = 0$  for  $k = 1, \dots, m$  with  $\nu_k$  arbitrary, then  $\sum_i \lambda_i a_i + \sum_k \nu_k b_k \leq 0$ .*

*Proof.* Each  $\lambda_i a_i \leq 0$ : multiplication by a nonnegative element preserves  $\leq$  (applied to  $a_i \leq 0$ ), so  $\lambda_i a_i \leq \lambda_i \cdot 0 = 0$ . Each  $\nu_k b_k = \nu_k \cdot 0 = 0$  regardless of the sign of  $\nu_k$  — this sign-blindness on equality atoms is precisely the freedom classical Farkas variants grant multipliers of equality constraints [216, §7.3]. A finite sum of nonpositive elements is nonpositive, by induction on  $n + m$ .  $\square$

**Lemma R33.2** (the certified identity evaluates). *Let  $(*)$  hold as an identity of canonical polynomials, and let  $\sigma$  be a valuation at which  $c$  and every  $e_i, g_k$  evaluate (per-entry, through the clamped per-entry valuation for tensor shapes). Then the rational identity  $c(\sigma) = \sum_i \lambda_i e_i(\sigma) + \sum_k \nu_k g_k(\sigma)$  holds at every entry.*

*Proof.* First fix what “per-entry” means. For an entry index  $j$  of the conclusion's shape, the *clamped per-entry valuation* reads each wire at position  $j$  when  $j$  is in range for that wire's shape and at its entry 0 otherwise — total on every wire in sight, because the B14 positivity pack guarantees each carries at least one entry, and agreeing with the plain positional read wherever  $j$  is in range. No shape-agreement hypothesis is needed beyond that: a sourced polynomial's wires share its own atom's shape (rank-0 broadcast aside), so they clamp in step, and its clamped value at  $j$  is an honest entry of its own evaluated tensor — which is where Step 4's per-entry case split picks it up. Evaluation at this scalar assignment is a ring homomorphism  $\mathbb{Q}[\text{wires}] \rightarrow \mathbb{Q}$ ; a syntactic identity of canonical forms is an identity of polynomials, and ring homomorphisms preserve polynomial identities. Two remarks make this step deserve its own lemma. First,  $(*)$  is checked by *exact canonical-form equality* over  $\mathbb{Q}$  (syzygyCombinationValid, replayed through toPoly), not by evaluation at test points — so no completeness, degree bound, or interpolation argument is needed anywhere in this proof; soundness is pure arithmetic. Second, the checker admits three certified routes to the same fact (the idx-free branch, the wire-coordinate branch, and the mixed tagged-union branch: syzygyCheck = Core  $\vee$  W  $\vee$  M); whichever branch fires, the certified fact consumed downstream is the same — the identity  $(*)$ , under the same per-entry reading. The branches differ in how terms are decoded, never in what is certified.  $\square$

**Lemma R33.3** (reading transport). *Suppose  $\sigma$  satisfies the zero-normal atom  $c \leq 0$ . Then  $\sigma$  satisfies every formula  $F$  admitted by syzygyConclusionForm( $c, F$ ), namely: (Z $\leq$ )  $F = (c \leq 0)$  itself; (G)  $F = (e \geq 0)$  where  $c$  is literally the negation term  $-e$ ; (L $\leq$ )  $F = (l \leq r)$  where  $c$  is literally the difference term  $l - r$  — structural identities of terms, not merely canonical-polynomial ones.*

*Proof.* ( $Z \leq$ ) is the identity transport. (G): per entry,  $-e(\sigma) \leq 0 \iff e(\sigma) \geq 0$  (negate and flip, an ordered-field axiom). ( $L \leq$ ): per entry,  $l(\sigma) - r(\sigma) \leq 0 \iff l(\sigma) \leq r(\sigma)$  (add  $r(\sigma)$  to both sides). Structurality is load-bearing: because  $e, l, r$  are subterms of  $c$ , the evaluability that the zero-normal atom's holding certifies for  $c$  passes to them — a merely canonical identity would not carry evaluation (a cancelled ill-typed subterm vanishes from the polynomial yet still poisons the term), which is why the admitted readings are stated on term structure. This is the ge-bridge ring lemma `holds_of_syzygyConclusionForm` (the both-polarity conclusion-form design): the readings are one exact  $\mathbb{Q}$  identity re-presented under a sign flip, so the polarity bridge lives *once*, here, and every  $\leq 0$ -shaped rule (SYZYGY itself, PBOUND's compact spelling, the `PsdCert` family) inherits all readings with no separate justification.  $\square$

**Theorem R33.4** (soundness of SYZYGY = Lemma B, dialect D). *Under the payload's checked hypotheses, if every component sequent  $\Phi_i \vdash e_i \leq 0$  is semantically valid, then so is  $\Phi \vdash \Psi$ .*

*Proof.* Fix an admissible valuation  $\sigma$  with  $\sigma \models \Phi$ ; we must show  $\sigma \models \Psi$ .

*Step 1 (components hold at  $\sigma$ ).* For each  $i$ , the payload checks  $\Phi \supseteq \Phi_i$  conjunct-wise (premiseContains — an ordered-tree containment certificate, and satisfaction descends along it by one  $\wedge$ -projection per step); hence  $\sigma \models \Phi_i$ , and by the assumed semantic validity of the  $i$ -th component,  $\sigma \models e_i \leq 0$ : every entry of  $e_i(\sigma)$  is  $\leq 0$ .

*Step 2 (wiring identities hold at  $\sigma$ ).* Each  $g_k = 0$  is an equality sub-conjunct of  $\Phi$ , so  $\sigma \models g_k = 0$  directly:  $g_k(\sigma) = 0$  at every entry.

*Step 3 (the conclusion evaluates).* The B13 shape fields (`conclShape`, `conclFin`) guarantee  $c$  has a determinate finite Bernstein shape over  $H$ , and the B14 positivity fields (Remark R33.5) guarantee every wire in sight has positive total size; together these give a total per-entry evaluation of  $c$  at  $\sigma$  — the two-case shape analysis (singleton vs. indexed) in `sound_syzygy`'s body.

*Step 4 (combine).* At each entry, Lemma R33.2 turns the certified identity  $(*)$  into the rational identity  $c(\sigma) = \sum_i \lambda_i e_i(\sigma) + \sum_k \nu_k g_k(\sigma)$ ; the per-entry source discharge is the case split of Steps 1–2 (a component-sourced entry's atom holds by component validity, a wiring-sourced entry's atom holds as a premise sub-conjunct — `atomLeZeroPolys_sound_entryC` delivers per-entry nonpositivity in both cases), and Lemma R33.1 closes the fold:  $c(\sigma) \leq 0$  at every entry.

*Step 5 (read off).* Lemma R33.3 transports the zero-normal bound  $c \leq 0$  to whichever reading `syzygyConclusionForm`( $c, \Psi$ ) the payload declared (`postForm`). Hence  $\sigma \models \Psi$ .  $\square$

*Remark R33.5* (why the B14 hypotheses are not decoration). `wiresPos` and its honest extension `compPostWiresPos` require every wire appearing in  $\Phi$ 's free wires, the conclusion, and each component conclusion to have positive total size. Drop `compPostWiresPos` and the rule is *unsound*: a component conclusion over a zero-size wire holds *vacuously* (its evaluated tensor has no entries, so “every entry  $\leq 0$ ” is empty), yet its polynomial enters the combination  $(*)$  with full algebraic weight — a vacuously-held component can then push the composite conclusion to something false. Concretely: over a hypernet with one zero-size wire  $z$ , take the single component  $\top \vdash z - z + 1 \leq 0$  — vacuously valid, its evaluated tensor having no entries — with weight 1 and empty  $\nu$ -row; the combination's canonical polynomial is the constant 1, so the checked identity admits the conclusion  $1 \leq 0$ , a rank-0 falsehood concluded from a vacuous truth. (The counterexample is also kernel-checkable, recorded at the field's introduction.) The B13 shape fields have the matching witness one step earlier: with  $c$  the term  $w - w$  for an untyped wire  $w$ , the canonical polynomial is 0 — identical to the empty combination's — yet the conclusion atom never evaluates and so never holds; `conclShape` and `conclFin` exclude exactly this. This is the classic mismatch between empty-product semantics and nonempty algebra, caught by making the degenerate case unrepresentable rather than discouraged.

*Remark R33.6* (relation to the literature). The rule is the *sound* (easy) direction of an affine Farkas-type combination, lifted twice: atoms come from sub-*proofs* rather than sub-conjuncts, and atoms may have arbitrary polynomial degree. The linear ancestor is Farkas' lemma [73]; the textbook treatment of multiplier sign conventions ( $\lambda \geq 0$  on inequalities, free on equalities) is [216, §7]. With polynomial atoms the combination sits in the Krivine–Handelman family of positivity certificates [110, 144] — of which, again, only the trivial direction is claimed or needed: no Positivstellensatz completeness enters the kernel. The wiring reading — components as open subsystems,  $g_k = 0$  as power-preserving interconnection, the composite as dissipation of  $\sum_i \lambda_i V_i$  — is Tellegen's theorem [231] in certificate form, i.e. compositional dissipativity in the sense of Willems [239] and Moylan–Hill [184]; the port-Hamiltonian formulation is surveyed in [215]. Within the accompanying development the rule is known as Lemma B (dialect D); a quantitative effectivity result for tree-structured interconnections — sparse Handelman certificates with running-intersection support — is developed in a companion note.

| proof step                                             | formal anchor                                                                                                                                                                                            |

## Rule 34. SMALLGAIN (alias for SYZGYG)

### The rule (Steele metanotation)

as realized in the mechanized development; source row: `rules.toml` — *SmallGain*. The metanotation statement is typeset by hand for notational quality; its mechanized ground truth is the Lean statement below, extracted from the sources at every build of this book and hash-bound. The rule *roster* is machine-checked (every mechanized rule tag round-trips to exactly one catalogue row); the statement *text* is editorial, checked by eye against the extracted Lean beside it.

$$\frac{\Phi_1 \vdash e_1 \leq 0 \quad \Phi_2 \vdash e_2 \leq 0 \quad \Phi_w \vdash \lambda \sigma_2 - (1-\theta) \alpha_1 \leq 0 \quad \Phi_w \vdash \sigma_1 - \lambda(1-\theta) \alpha_2 \leq 0 \quad \Phi \supseteq \Phi_1, \Phi_2, \Phi_w \text{ conjunct-wise (checked)} \quad \lambda \in \mathbb{Q}_{>0} \quad \theta \in \mathbb{Q} \cap (0, 1)}{\Phi \vdash \mathcal{L}(V_1 + \lambda V_2) + \theta(\alpha_1 + \lambda \alpha_2) \leq 0} \text{ SMALLGAIN}$$

$e_i \equiv \mathcal{L}_i V_i + \alpha_i - \sigma_i$ ;  $m_1 \equiv \lambda \sigma_2 - (1-\theta) \alpha_1$ ,  $m_2 \equiv \sigma_1 - \lambda(1-\theta) \alpha_2$ ; conclusion identity, checked as exact canonical polynomial:  $e_1 + \lambda e_2 + m_1 + m_2 = \mathcal{L}(V_1 + \lambda V_2) + \theta(\alpha_1 + \lambda \alpha_2)$ .

the two membership sequents are ordinary BL sequents over the declared operating box  $\Phi_w$ , their BERNCONe multipliers *are* the LP witness; in the conclusion identity the cross-supplies cancel by construction — the checker never sees a fixpoint. In the baked base theory this rule sits in the admissible roster — no proof-term sort, no wire tag: it elaborates to one SYZGYG node at weights  $(1, \lambda, 1, 1)$ , which this catalogue renders as the alias tier.

SMALLGAIN is the calculus's feedback-composition rule in its classical costume: two subsystems, each dissipating its own storage function except for a supply fed by the other, compose into a single dissipation certificate for  $V_1 + \lambda V_2$  when the loop gain is strictly less than one ( $\theta$  is the margin). It is an *alias*: the wire format never carries a SMALLGAIN node. A producer that finds  $(\lambda, \theta)$  — an LP feasibility problem over the membership certificates — elaborates the step to the single SYZGYG node displayed in the recipe below before emission, so what the checker recomputes is exactly SYZGYG's obligation set: the exact conclusion identity at weights  $(1, \lambda, 1, 1)$ , in which the cross-supplies cancel by construction. Nothing fixpoint-shaped survives to checking time; the classical contraction argument lives entirely on the producer's side, in the choice of  $(\lambda, \theta)$ .

What would break without each hypothesis is inherited from SYZGYG through the unpack — that section's commentary applies verbatim to the unpacked node. The two conditions native to this rule:  $\lambda > 0$ , of which soundness uses only  $\lambda \geq 0$  (the strictness backs the rule's published meaning), and  $\theta \in (0, 1)$ , which is well-formedness for  $\theta$ 's published meaning as a robustness margin rather than a soundness need — the membership sequents self-police, and an infeasible pair simply yields unprovable memberships.

**notes** The four component sequents are ordinary sequents over the declared operating box; their cone-membership multipliers *are* the LP witness. Signed polynomial contracts (rather than norm gains) are constitutive, not stylistic: swing-up analyses in the Åström–Furuta family exploit the *sign* of  $\dot{\vartheta} \cos \vartheta$ , which no norm-gain contract can express.  $(\lambda, \theta)$ -existence stays on the producer side, deliberately outside the checker; the  $n$ -component generalization is the SMALLGAINN section — the same alias discipline over an arbitrary interconnection graph, elaborating to one SYZGYG node, of which this rule is the  $n = 2$  instance.

### Lean statement

BernsteinLogic.Composition . SmallGainStep

statement bound

```
-- Applicability data of the SmallGain rule – field-for-field the
-- draft's `smallGainShapes` obligations (§3.3):

* (a) the dissipation conclusions are `(e_i ≤ 0)` atoms – the residual
    reading  $e_i = \mathcal{L}_i V_i + \alpha_i - \sigma_i$  is definitional at the checker level
    ( $\mathcal{L}_i V_i := e_i - \alpha_i + \sigma_i$ ), so no separate field pins it;
* (b) the membership conclusions are `(m_i ≤ 0)` atoms whose polynomials
    equal their schema instances at  $(\lambda, \theta)$  – exact canonical polynomial;
* (c)  $\lambda > 0$  and  $0 < \theta < 1$  – three rational comparisons. The  $\theta$  range is
    NOT consumed by soundness (the memberships self-police; the range backs
    the published guard-modulus semantics – draft §3.2's honesty note);
* (d) the conclusion identity: the  $(1, \lambda, 1, 1)$  fold of the four posted
    polynomials equals the conclusion schema  $\mathcal{L}(V_1 + \lambda V_2) + \theta(\alpha_1 + \lambda \alpha_2)$  – the
    checker replays the cancellation (`smallGain_is_syzygy` proves the
    schema coherent: given (b) and the residual reading, (d) is a theorem,
    not a search).

## Correspondence (Steele display $\leftrightarrow$ Lean)

**reviewer-certified against the displayed texts** The dictionary below is a reviewer-certified statement of how the mechanized statements above interpret the displayed rule: display metavariable  $\mapsto$  Lean binder, each display hypothesis  $\mapsto$  the premise or side condition carrying it, the display conclusion  $\mapsto$  the goal — with any deliberate difference in width between display and mechanization named outright. Certification is recorded as a hash triple over (the displayed cell, the extracted statement texts, this dictionary's own text); if any of the three changes, this block turns amber until a reviewer re-certifies. The correspondence claim itself remains editorial — reviewer-grade, not machine-checked; its machine-checked successor types each soundness statement against the rule as a structured object, and supersedes this block per rule as it lands.

The alias's Lean vehicle is the payload structure `SmallGainStep H` (quoted in full above — its fields carry the display's metavariables), the verified unpack `toSyzygy`, and the soundness corollary `sound_smallGain`.

- $\lambda \mapsto \text{lambda} : \mathbb{Q}$  with  $\text{lambdaPos} : 0 < \lambda$ ;  $\theta \mapsto \text{theta}$  with  $\text{thetaLo}, \text{thetaHi} : 0 < \theta < 1$ ;  $\alpha_i, \sigma_i \mapsto \text{alpha1/alpha2}, \text{sigma1/sigma2}$ ; the composite storage  $V_1 + \lambda V_2 \mapsto \text{lyapTerm}$ .
- the dissipation premises  $\Phi_i \vdash e_i \leq 0 \mapsto \text{diss1/diss2}$  with the shape ties  $\text{diss1Post/diss2Post}$  (each  $e_i$  is a field; its published spelling  $\mathcal{L}_i V_i + \alpha_i - \sigma_i$  lives on the producer's side). The operating-box membership premises  $\mapsto \text{mem1/mem2}$  with  $\text{mem1Poly/mem2Poly}$  tying their residuals to the displayed schemas  $\lambda \sigma_2 - (1-\theta)\alpha_1$  and  $\sigma_1 - \lambda(1-\theta)\alpha_2$  as canonical polynomials.
- the display's side text — the exact conclusion identity (the cross-supply-cancellation gloss is the flavor text's) —  $\mapsto \text{foldEq}$  and  $\text{conclPoly}$  (the checker-replayed cancellation, exact over canonical polynomials) plus  $\text{postEq}$  (the conclusion tie); the displayed containment premise ( $\Phi \supseteq \Phi_1, \Phi_2, \Phi_w$  conjunct-wise)  $\mapsto \text{pre1/pre2/preM1/preM2}$ .
- conclusion  $\Phi \vdash \mathcal{L}(V_1 + \lambda V_2) + \theta(\alpha_1 + \lambda \alpha_2) \leq 0 \mapsto$  the goal `st.seq.semanticallyValid H` of `sound_smallGain`, whose four hypotheses are exactly the component validities.
- the alias artefacts: the unpack function is `toSyzygy` (weights (1, λ, 1, 1), components in combination order); the soundness corollary routes through the target rule's lemma on the collapsed instance — the displayed rule never reaches the wire.

Width notes, both directions: soundness uses only  $\lambda \geq 0$  of `lambdaPos` (the strictness backs the rule's published meaning), and  $\theta$ 's range is well-formedness rather than a soundness need — both as the commentary states. Conversely the structure carries `idxFree` and wire-shape fields (`e1IdxFree` through `compPostWiresPos`) that the display leaves to the ambient calculus's conventions: the mechanization is narrower there, naming every side condition the checker replays.

## Lean verifier receipts

module BernsteinLogic.Composition; bound build 9116f454beb0... (bound from receipt 548ea3dda8ed73a2, 2026-08-03T21:30:29Z). A receipt records that named checking layers accepted a build: (module, compiled-artifact SHA-256, environment SHA-256, checker layers), minted when the checking gate ran; the store receipts attesting the bound build are listed with the layers each run credited. Nothing here asks the reader to trust the store: every layer is an independently runnable program over the quoted sources — rebuild the module and re-run the checkers to reproduce the verdict. Receipts attesting superseded builds credit no layer and are omitted from this rendering (the count of omissions, if any, is noted below).

| receipt          | minted               | layers             | status  |
|------------------|----------------------|--------------------|---------|
| 548ea3dda8ed73a2 | 2026-08-03T21:30:29Z | build+decorrelated | current |

10 further receipt(s) in the store attest superseded builds of this module and are omitted from this rendering.

### gate-layer coverage of the bound build:

build (lake build (elaboration)) current

replay (leanchecker (official kernel replay)) stale only

hardened (safe\_verify (hardened screen)) stale only

decorrelated (lean4export + nanoda (decorrelated kernel)) current

comparator: structurally n/a the alias unpacks *before* emission (no rule tag; producers elaborate a SMALLGAIN step to its SYZYGY node), so no wire certificate — and hence no comparator fixture — can ever contain a SMALLGAIN node. Comparator coverage for this rule is SYZYGY's. The end-to-end instance `DpCompositeSmallGain.lean` is kernel-checked upstream of the unpack.

## HOL4 statement

### OUT OF SCOPE BY DESIGN

Out of scope for the HOL side *by design*, not by backlog: the wire format never carries a SMALLGAIN node (no tag — producers elaborate to the  $(1, \lambda, 1, 1)$  SYZYGY node before emission, warrant `SmallGainStep.toSyzygy`), and the HOL4 development's object is the wire checker. The HOL statement that verifies a composed small-gain certificate is therefore SYZYGY's (`syzygyCheck`, previous section); an independent HOL port of the alias's unpack function would be new assurance surface only if HOL-side producers ever emit SMALLGAIN steps directly.

## HOL verifier receipts

### NONE

no HOL verification receipt exists for this rule.

## Proof

Genre: alias rule (tier 3) — a respelling template. An alias owes the book five artefacts: the verified  $1 \rightarrow 1$  unpack function, the filled-in application of the target rule, the payload-transport table, the exact algebraic identity that makes the respelling correct, and the soundness corollary through the target rule's lemma. All five follow. (The tier criterion counts derivation nodes, not instantiation work: the unpack *computes* the weighting, but its image is a single SYZYGY node, so the rule is an alias.)

**Recipe R34.1** (the alias template). An alias rule  $A$  is warranted by a verified function  $\text{unpack} : \text{Step}_A \rightarrow \text{Step}_T$  into the payload of a *single* target node  $T$  (core or admissible), such that the  $A$ -node and its image conclude the same sequent from the same premises: one node  $\rightarrow$  one node, payload transported, nothing derived. Soundness is then a corollary,  $\text{sound}_A = \text{sound}_T \circ \text{unpack}$ , and the wire format need never carry  $A$  at all — producers elaborate before emission, which is why SMALLGAIN has no `RuleTag`.

**Recipe R34.2** (the filled-in application — SMALLGAIN's premises rewritten *into* the SYZYGY instance). A SMALLGAIN step carries four component proofs: the two dissipation sequents (over their own boxes  $\Phi_1, \Phi_2$ ) and the two gain-membership sequents (over the declared operating box  $\Phi_w$ ). Define the four atom terms and the substitution into SYZYGY's metavariables:

$$e_1 \equiv \mathcal{L}_1 V_1 + \alpha_1 - \sigma_1, \quad e_2 \equiv \mathcal{L}_2 V_2 + \alpha_2 - \sigma_2, \quad m_1 \equiv \lambda \sigma_2 - (1-\theta) \alpha_1, \quad m_2 \equiv \sigma_1 - \lambda(1-\theta) \alpha_2,$$

$$n := 4, \quad (e_1, e_2, e_3, e_4) := (e_1, e_2, m_1, m_2), \quad (\Phi_1, \Phi_2, \Phi_3, \Phi_4) := (\Phi_1, \Phi_2, \Phi_w, \Phi_w),$$

$$(\lambda_1, \lambda_2, \lambda_3, \lambda_4) := (1, \lambda, 1, 1), \quad \{g_k\}_k := \emptyset \text{ (no equality entries)}, \quad c := \mathcal{L}(V_1 + \lambda V_2) + \theta(\alpha_1 + \lambda \alpha_2),$$

with  $\lambda \in \mathbb{Q}_{>0}$  and  $\theta \in \mathbb{Q} \cap (0, 1)$  from the payload. Under this substitution the SMALLGAIN node is the following SYZYGY application (compare the rule display in the SYZYGY section, field for field):

$$\frac{\begin{array}{c} \Phi_1 \vdash e_1 \leq 0 \quad \Phi_2 \vdash e_2 \leq 0 \quad \Phi_w \vdash m_1 \leq 0 \quad \Phi_w \vdash m_2 \leq 0 \\ (1, \lambda, 1, 1) \in \mathbb{Q}_{\geq 0}^4 \quad c \equiv 1 \cdot e_1 + \lambda \cdot e_2 + 1 \cdot m_1 + 1 \cdot m_2 \text{ (exact canonical polynomial)} \end{array}}{\Phi \vdash c \leq 0} \text{SYZYGY}$$

with  $\Phi \supseteq \Phi_1, \Phi_2, \Phi_w$  conjunct-wise (the four-way `preContains` split). Discharging SYZYGY's obligations at this instance: the nonnegativity checks are  $1 \geq 0$  (three times) and  $\lambda \geq 0$  (from  $\lambda > 0$  — the *only* use soundness makes of  $\lambda$ 's sign); the sourcing check is immediate (each of the four entries is the corresponding component's posted atom, verbatim); and the exact-identity check is Proposition R34.3 below; the five index-freeness gates (the four posted residuals and the composite conclusion carry no free indices — recomputed syntactic checks, the G1 rider that lets canonical polynomials carry the rule's meaning) discharge by recomputation on the five terms; the remaining obligations — the B13 shape pack, the B14 positivity pack, and the zero-normal `postForm` declaration — transport verbatim, per Recipe R34.4. The dead premise slots of SYZYGY are honestly dead: no equality sub-conjuncts of  $\Phi$  enter (the  $\nu$ -row is empty), because the cross-supply cancellation is performed by the membership atoms themselves. The verified function computing this rewriting is `SmallGainStep.toSyzygy`, quoted above.

**Proposition R34.3** (the conclusion identity). *As an identity of exact canonical polynomials,*

$$e_1 + \lambda e_2 + m_1 + m_2 = \mathcal{L}(V_1 + \lambda V_2) + \theta(\alpha_1 + \lambda \alpha_2).$$

*Proof.* Expand and collect — two lines, which is the point:

$$\begin{aligned} e_1 + \lambda e_2 + m_1 + m_2 &= (\mathcal{L}_1 V_1 + \lambda \mathcal{L}_2 V_2) + \alpha_1 + \lambda \alpha_2 \underbrace{- \sigma_1 - \lambda \sigma_2 + \lambda \sigma_2 + \sigma_1}_{= 0 \text{ (cross-supplies cancel)}} - (1-\theta)\alpha_1 - \lambda(1-\theta)\alpha_2 \\ &= \mathcal{L}(V_1 + \lambda V_2) + (1 - (1-\theta))\alpha_1 + \lambda(1 - (1-\theta))\alpha_2 = \mathcal{L}(V_1 + \lambda V_2) + \theta(\alpha_1 + \lambda \alpha_2). \end{aligned}$$

The final rewrite reads  $\mathcal{L}(V_1 + \lambda V_2)$  for  $\mathcal{L}_1 V_1 + \lambda \mathcal{L}_2 V_2$ , and that is a definition, not a step: over disjoint variable sets the composite generator acts coordinate-wise, so the composite storage-rate term — the payload’s `lyapTerm`, pinned to exactly this sum by the exact canonical ties (`foldEq · conclPoly`) — has  $\mathcal{L}(V_1 + \lambda V_2)$  as its published spelling. The cross-supply cancellation is *by construction of the multipliers*: the membership sequents were chosen so that their polynomials supply exactly  $+\lambda\sigma_2$  and  $+\sigma_1$ . The checker replays this as `Syzygy`’s exact canonical-polynomial identity (\*) and **never sees a fixpoint** — the classical small-gain contraction argument is dissolved into two lines of ring arithmetic at certificate-checking time.  $\square$

**Recipe R34.4** (payload transport — `toSyzygy`, field for field).

| SmallGainStep                                | SyzygyStep                                                                 |

| <code>diss1, diss2, mem1, mem2</code>        | <code>components</code> (that order = combination order)                   |
| <code>combTerm (weights (1, λ, 1, 1))</code> | <code>combination</code>                                                   |
| <code>concl</code>                           | <code>conclusion</code>                                                    |
| <code>pre1, pre2, preM1, preM2</code>        | <code>preContains</code> (four-way case split)                             |
| <code>conclShape, conclFin</code>            | <code>conclShape, conclFin</code> (verbatim)                               |
| <code>wiresPos, compPostWiresPos</code>      | <code>wiresPos, compPostWiresPos</code> (verbatim)                         |
| <code>e1/e2/m1/m2/conclIdxFree</code>        | consumed by <code>combValid</code> $\mapsto$ <code>valid</code> (G1 gates) |
| <code>combValid</code>                       | <code>valid</code>                                                         |
| <code>postEq</code>                          | <code>postForm = (Z≤)</code> , the zero-normal reading                     |

The alias declares the *zero-normal* reading of the both-polarity conclusion form: `SMALLGAIN`’s own contract stays  $\leq$ -only, and any polarity flexibility is inherited from `Syzygy`’s side of the fence (the reading-transport lemma `holds_of_syzygyConclusionForm`, proved in the `Syzygy` section), not re-justified here.

**Proposition R34.5** (soundness corollary). *If the four component sequents are semantically valid, the composite sequent  $\Phi \vdash \mathcal{L}(V_1 + \lambda V_2) + \theta(\alpha_1 + \lambda \alpha_2) \leq 0$  is semantically valid.*

*Proof.* `sound_smallGain` = `sound_syzygy` applied to `st.toSyzygy`, feeding the four validities through the four-way membership case split. Beyond that routing there is no further argument — the alias genre working as intended.  $\square$

**Remark R34.6** ( $\theta$ ’s range is well-formedness, not soundness). The identity of Proposition R34.3 holds at *any*  $\theta$ ; the memberships self-police: an infeasible  $(\lambda, \theta)$  makes the required membership inequalities false over the operating box, so no sound certificate can discharge them. The  $(0, 1)$  range check backs the *published meaning* of  $\theta$  as a guard modulus — a first-class robustness radius travelling in the proof term, per-node in the payload, with the certificate header publishing the composite modulus as the min over nodes — and  $\lambda > 0$  enters soundness only as  $\lambda \geq 0$ .

**Remark R34.7** (relation to the literature). The rule certificate-izes the Lyapunov small-gain construction: two ISS-style dissipation inequalities with gain interconnection conditions yield a composite Lyapunov function  $V_1 + \lambda V_2$  — the nonlinear small-gain theorem of Jiang–Teel–Prly [126] in its Lyapunov formulation [125], sitting inside the dissipativity-composition tradition [184, 239]. Where the classical theorems close a fixpoint/contraction argument, the certificate form closes a ring identity: the analytic content is moved into the *choice* of  $(\lambda, \theta)$  and the membership certificates, and the kernel checks only arithmetic. The contracts are *signed polynomial* inequalities rather than norm gains for cause: Åström–Furuta’s swing-up analysis [9] exploits the sign of  $\dot{\vartheta} \cos \vartheta$ , information a pure norm-gain contract does not record.  $(\lambda, \theta)$ -existence results are deliberately outside the checker; the  $n$ -component generalization over arbitrary interconnection graphs [59] is catalogued as `SMALLGAINN` — the same alias discipline, one `Syzygy` node, with this rule as its  $n = 2$  instance.

## Rule 35. SMALLGAINN (alias for SYZGY)

### The rule (Steele metanotation)

as realized in the mechanized development; source row: `rules.toml` — *SmallGainN*. The metanotation statement is typeset by hand for notational quality; its mechanized ground truth is the Lean statement below, extracted from the sources at every build of this book and hash-bound. The rule *roster* is machine-checked (every mechanized rule tag round-trips to exactly one catalogue row); the statement *text* is editorial, checked by eye against the extracted Lean beside it.

$$\frac{\Phi \supseteq \Phi_1, \dots, \Phi_n, \Phi_w \text{ conjunct-wise (checked)} \quad \frac{\{\Phi_i \vdash e_i \leq 0\}_{i=1}^n \quad \lambda \in \mathbb{Q}_{>0}^n \quad \frac{\{\Phi_w \vdash m_i \leq 0\}_{i=1}^n \quad B \in \mathbb{Q}_{\geq 0}^{n \times n} \quad \sum_i B_{ij} = \lambda_j \ (\forall j) \quad \theta \in \mathbb{Q} \cap (0, 1)}{\Phi \vdash \mathcal{L}(\sum_i \lambda_i V_i) + \theta \sum_j \lambda_j \alpha_j \leq 0}}{\text{SMALLGAINN}}$$

$e_i \equiv \mathcal{L}_i V_i + \alpha_i - \sigma_i$ ;  $m_i \equiv \lambda_i \sigma_i - (1 - \theta) \sum_j B_{ij} \alpha_j$  (the repayment matrix's membership rows); conclusion identity, checked as exact canonical polynomial:  $\sum_i \lambda_i e_i + \sum_i m_i = \mathcal{L}(\sum_i \lambda_i V_i) + \theta \sum_j \lambda_j \alpha_j$  under the column condition.

the  $n$  membership sequents are ordinary BL sequents over the declared operating box  $\Phi_w$ , their BERNCONe multipliers *are* the LP witness; the repayment matrix  $B$  routes each component's supply through its neighbours, and the column condition  $\sum_i B_{ij} = \lambda_j$  makes every cross-supply cancel in the conclusion identity — the checker never sees a fixpoint, a spectral radius, or the interconnection graph. Like the binary rule it is an alias: no proof-term sort, no wire tag; it elaborates to one SYZGY node at weights  $(\lambda_1, \dots, \lambda_n, 1, \dots, 1)$ , and  $B$  itself never reaches the wire (the membership rows carry it; the exact identity is the whole obligation). The binary rule is the  $n = 2$  instance on the nose:  $\lambda = (1, \lambda)$ ,  $B_{21} = 1$ ,  $B_{12} = \lambda$  reproduce SMALLGAIN's membership rows and its  $(1, \lambda, 1, 1)$  weights.

SMALLGAINN is the  $n$ -component quantitative small-gain rule:  $n$  subsystems on an arbitrary directed interconnection graph, each dissipating its own storage function except for supplies fed by its neighbours, compose into a single dissipation certificate for the weighted sum  $\sum_i \lambda_i V_i$  when a weighted loop-gain condition holds with margin  $\theta$ . The graph structure enters through the *repayment matrix*  $B$ : the membership row  $m_i \equiv \lambda_i \sigma_i - (1 - \theta) \sum_j B_{ij} \alpha_j$  charges component  $i$ 's incoming supply against a  $(1 - \theta)$ -discounted draw on its neighbours' decay budgets, and the column condition  $\sum_i B_{ij} = \lambda_j$  says every component's budget is drawn on at exactly its weight in the composite — which is what makes the cross-supplies cancel identically in the conclusion.

Like the binary rule, it is an *alias*: the wire format never carries a SMALLGAINN node, and the checker gains no new obligation kind. A producer that finds  $(\lambda, B, \theta)$  — an LP feasibility problem over the membership certificates; when the gain matrix has spectral radius below  $1 - \theta$ , a Neumann-series weight vector witnesses feasibility, so the classical spectral small-gain condition is exactly an existence theory for this rule's side data — elaborates the step to a single SYZGY node at weights  $(\lambda_1, \dots, \lambda_n, 1, \dots, 1)$  before emission. What the checker recomputes is exactly SYZGY's obligation set: the exact conclusion identity over canonical polynomials. Neither the graph, nor  $B$ , nor anything fixpoint- or spectrum-shaped survives to checking time.

What would break without each hypothesis is inherited from SYZGY through the unpack — that section's commentary applies verbatim to the unpacked node. The conditions native to this rule:  $\lambda_i > 0$ , of which soundness uses only  $\lambda_i \geq 0$  (strictness backs the published meaning: every component genuinely participates);  $\theta \in (0, 1)$ , well-formedness for  $\theta$ 's published meaning as a robustness margin (the identity holds at any  $\theta$ ; the memberships self-police); and the column condition, which is well-formedness at the *schema* level — it is what makes the membership rows deliver the stated conclusion for every decay budget  $\alpha$ , while at any concrete instance the exact identity subsumes it: an emitted node whose identity checks is sound regardless of how the producer bookkept  $B$ .

The binary rule is the  $n = 2$  instance on the nose:  $\lambda = (1, \lambda)$ ,  $B_{21} = 1$ ,  $B_{12} = \lambda$  reproduce SMALLGAIN's membership rows (as a set — the two rows arrive in the opposite order, a bookkeeping difference in combination order) and its  $(1, \lambda, 1, 1)$  weights.

**notes** The  $n$ -component small-gain theorem for general interconnection topologies is Dashkovskiy–Rüffer–Wirth [59]; this rule is its certificate form, with the cycle/spectral conditions of that tradition dissolved into the producer's choice of  $(\lambda, B, \theta)$  and the checker replaying only ring arithmetic. Signed polynomial contracts rather than norm gains, for the same cause as the binary section. The dedicated  $n$ -ary payload vehicle is mechanized as the binary rule's pattern at arbitrary  $n$ : the exact identity (`smallGainN_is_syzgy` — the cross-supplies cancel under the column condition, by canonical-polynomial extensionality), the payload structure with its verified collapse (`SmallGainNStep.toSyzgy`, weights  $(\lambda_1, \dots, \lambda_n, 1, \dots, 1)$ ), the soundness corollary (`sound_smallGainN`), and the column condition's necessity as a machine-checked mutant (`smallGainN_colSum_mutant_refuted`: delete it and a one-component instance separates fold from conclusion, by decide). The semantic face lives beside the binary one's in the discrete-kernel module: `smallGainN_drift` with its assembled avoid bound, and the binary recovery on the nose (`smallGain_drift_of_N`:  $\lambda = (1, \lambda)$ ,  $B_{21} = 1$ ,  $B_{12} = \lambda$  reproduce the binary rows — order-swapped, set-equal, as the commentary states). Every *emitted* instance remains checked and warranted as SYZGY's node: the alias unpacks before emission.

BernsteinLogicAux.QtslCompose.AGComposeDiscrete . **smallGain\_drift\_of\_N**

statement bound

```

/-- **Binary recovery, on the nose**: `smallGain_drift`'s exact statement
re-derived from `smallGainN_drift` at `m = 2`, `lam = ![1, λ]`,
`B = ![![0, λ], ![1, 0]]` (column sums `0 + 1 = 1` and `λ + 0 = λ`). One
bookkeeping disanalogy, inherited from the catalogue commentary: the n-ary
membership row at `i = 0` reads `1 * σ₁ ≤ (1-θ)·λ·α₂` — the binary `hm₂`
with its factors reassociated — and at `i = 1` reads `λ * σ₂ ≤ (1-θ)·α₁` =
the binary `hm₁`; the two rows arrive order-swapped vs the binary labels,
set-equal. -/

**comparator:** **structurally n/a** the alias unpacks *before* emission (no rule tag; producers elaborate a SMALLGAINN step to its SYZYGY node), so no wire certificate — and hence no comparator fixture — can ever contain a SMALLGAINN node. Comparator coverage for this rule is SYZYGY's.

## HOL4 statement

### OUT OF SCOPE BY DESIGN

Out of scope for the HOL side *by design*, not by backlog, and for exactly the binary rule's reason: the wire format never carries a SMALLGAINN node — producers elaborate to the  $(\lambda_1, \dots, \lambda_n, 1, \dots, 1)$  SYZYGY node before emission — and the HOL4 development's object is the wire checker. The HOL statement that verifies a composed  $n$ -component small-gain certificate is therefore SYZYGY's (syzygyCheck).

## HOL verifier receipts

### NONE

no HOL verification receipt exists for this rule.

## Proof

Genre: alias rule (tier 3) — a respelling template. The five artefacts an alias owes the book: the  $1 \rightarrow 1$  unpack, the filled-in application of the target rule, the payload-transport table, the exact algebraic identity that makes the respelling correct, and the soundness corollary through the target rule's lemma. All five follow; the unpack and transport table are stated here as the producer's contract, their dedicated mechanized vehicle being the one artefact not yet in the Lean tree (stated loudly below and in the section's Lean cell) — soundness of every emitted node meanwhile rests on the target rule's already-mechanized lemma, because the alias unpacks before emission.

**Recipe R35.1** (the unpack — one node, any  $n$ ). A SMALLGAINN step carries  $2n$  component proofs: the  $n$  dissipation sequents (each over its own box  $\Phi_i$ ) and the  $n$  membership sequents (over the declared operating box  $\Phi_w$ ), with side data  $\lambda \in \mathbb{Q}_{>0}^n$ ,  $B \in \mathbb{Q}_{\geq 0}^{n \times n}$  with  $\sum_i B_{ij} = \lambda_j$  for every  $j$ , and  $\theta \in \mathbb{Q} \cap (0, 1)$ . Define the atom terms

$$e_i \equiv \mathcal{L}_i V_i + \alpha_i - \sigma_i, \quad m_i \equiv \lambda_i \sigma_i - (1-\theta) \sum_j B_{ij} \alpha_j,$$

and the substitution into SYZYGY's metavariables:

$$N := 2n, \quad (e_1, \dots, e_N) := (e_1, \dots, e_n, m_1, \dots, m_n), \quad (\Phi_1, \dots, \Phi_N) := (\Phi_1, \dots, \Phi_n, \underbrace{\Phi_w, \dots, \Phi_w}_n),$$

$$(\lambda_1, \dots, \lambda_N) := (\lambda_1, \dots, \lambda_n, 1, \dots, 1), \quad \{g_k\}_k := \emptyset, \quad c := \mathcal{L}(\sum_i \lambda_i V_i) + \theta \sum_j \lambda_j \alpha_j.$$

The repayment matrix  $B$  is consumed here and does not appear in the image: it is the producer's bookkeeping for *finding* membership rows that make the identity of Proposition R35.3 true, and the identity is the only trace of it the checker ever replays.

**Recipe R35.2** (the filled-in application). Under the substitution of Recipe R35.1 the SMALLGAINN node is the following SYZYGY application:

$$\frac{(\lambda_1, \dots, \lambda_n, 1, \dots, 1) \in \mathbb{Q}_{\geq 0}^{2n} \quad \{ \Phi_i \vdash e_i \leq 0 \}_{i=1}^n \quad \{ \Phi_w \vdash m_i \leq 0 \}_{i=1}^n}{c \equiv \sum_i \lambda_i e_i + \sum_i 1 \cdot m_i \text{ (exact canonical polynomial)}}_{\Phi \vdash c \leq 0} \text{SYZYGY}$$

with  $\Phi \supseteq \Phi_1, \dots, \Phi_n, \Phi_w$  conjunct-wise (the  $2n$ -way containment split). Discharging SYZYGY's obligations at this instance: the nonnegativity checks are  $\lambda_i \geq 0$  (from  $\lambda_i > 0$  — the only use soundness makes of the signs) and  $1 \geq 0$ ,  $n$  times each; the sourcing check is immediate (each of the  $2n$  entries is the corresponding component's posted atom, verbatim); the exact-identity check is Proposition R35.3; the index-freeness gates discharge by recomputation on the  $2n + 1$  terms; and the shape, positivity, and zero-normal postForm obligations transport exactly as in the binary section. The  $\nu$ -row is empty for the same reason as there: the cross-supply cancellation is performed by the membership atoms themselves, so no equality sub-conjuncts of  $\Phi$  enter.

**Proposition R35.3** (the conclusion identity). *Under the column condition  $\sum_i B_{ij} = \lambda_j$  (all  $j$ ), as an identity of exact canonical polynomials,*

$$\sum_i \lambda_i e_i + \sum_i m_i = \mathcal{L}(\sum_i \lambda_i V_i) + \theta \sum_j \lambda_j \alpha_j.$$

*Proof.* Expand and collect — still two lines at any  $n$ , which is the point:

$$\begin{aligned} \sum_i \lambda_i e_i + \sum_i m_i &= \sum_i \lambda_i \mathcal{L}_i V_i + \sum_i \lambda_i \alpha_i - \underbrace{\sum_i \lambda_i \sigma_i + \sum_i \lambda_i \sigma_i}_{= 0 \text{ (cross-supplies cancel)}} - (1-\theta) \sum_j \left( \sum_i B_{ij} \right) \alpha_j \\ &= \mathcal{L}(\sum_i \lambda_i V_i) + \sum_j (1 - (1-\theta)) \lambda_j \alpha_j = \mathcal{L}(\sum_i \lambda_i V_i) + \theta \sum_j \lambda_j \alpha_j, \end{aligned}$$

where the second line swaps the summation order in the  $B$ -term and applies the column condition  $\sum_i B_{ij} = \lambda_j$  — the one place it is used, and exactly the discount that makes the neighbour draws rejoin the decay budgets at weight  $\lambda_j$ . As in the binary section, reading  $\mathcal{L}(\sum_i \lambda_i V_i)$  for  $\sum_i \lambda_i \mathcal{L}_i V_i$  is a definition, not a step: over disjoint variable sets the composite generator acts coordinate-wise. The checker replays this as SYZYGY's exact canonical-polynomial identity and never sees a fixpoint, a spectral radius, or the interconnection graph — the  $n$ -component small-gain argument is dissolved into ring arithmetic at certificate-checking time.  $\square$

**Proposition R35.4** (binary recovery, on the nose). *At  $n = 2$  with  $\lambda = (1, \lambda)$ ,  $B_{21} = 1$ ,  $B_{12} = \lambda$  (and  $B_{11} = B_{22} = 0$ ), the column condition holds, the membership rows are exactly the binary section's  $\{\lambda \sigma_2 - (1-\theta)\alpha_1, \sigma_1 - \lambda(1-\theta)\alpha_2\}$ , the conclusion is exactly  $\mathcal{L}(V_1 + \lambda V_2) + \theta(\alpha_1 + \lambda \alpha_2) \leq 0$ , and the SYZYGY weights are  $(1, \lambda, 1, 1)$  — i.e. SMALLGAIN is the  $n = 2$  instance of this rule.*

*Proof.* Column sums:  $B_{11} + B_{21} = 1 = \lambda_1$  and  $B_{12} + B_{22} = \lambda = \lambda_2$ . Membership rows:  $m_1 = \sigma_1 - \lambda(1-\theta)\alpha_2$  and  $m_2 = \lambda \sigma_2 - (1-\theta)\alpha_1$  — the binary section's rows as a *set*, arriving in the opposite order (its  $m_1$  is this rule's  $m_2$ ): a bookkeeping difference in combination order, visible in the node bytes and irrelevant to validity, since SYZYGY's identity is a sum. Conclusion and weights read off directly.  $\square$

**Recipe R35.5** (payload transport — the producer's contract). The  $n$ -ary payload transports into SyzygyStep exactly as the binary payload does, with the four fixed slots generalized to  $n$ -vectors:

| SMALLGAINN step (contract)                                                            | SyzygyStep                                        |
|---------------------------------------------------------------------------------------|---------------------------------------------------|
| seq                                                                                   | seq                                               |
| diss <sub>1</sub> , ..., diss <sub>n</sub> , mem <sub>1</sub> , ..., mem <sub>n</sub> | components (that order = combination order)       |
| weights $(\lambda_1, \dots, \lambda_n, 1, \dots, 1)$                                  | combination                                       |
| concl                                                                                 | conclusion                                        |
| 2n-way containment split                                                              | preContains                                       |
| shape/positivity/idx-freeness packs $(\lambda, B, \theta)$                            | verbatim, as in the binary table                  |
| postEq                                                                                | consumed by the unpack; $B$ leaves no image field |
|                                                                                       | postForm = the zero-normal reading                |

This table is the contract of the dedicated mechanized vehicle — the  $n$ -ary payload structure with its verified unpack and soundness corollary, the binary section's SmallGainStep apparatus at arbitrary  $n$  — which is not yet in the Lean tree (the section's Lean cell states the absence). Nothing checked on the wire waits on it: the unpack happens producer-side, and the emitted node is SYZYGY's.

**Proposition R35.6** (soundness corollary). *If the  $2n$  component sequents are semantically valid, the composite sequent  $\Phi \vdash \mathcal{L}(\sum_i \lambda_i V_i) + \theta \sum_j \lambda_j \alpha_j \leq 0$  is semantically valid.*

*Proof.* The target rule's kernel lemma applied to the unpacked instance of Recipe R35.2, feeding the  $2n$  validities through the containment split; the exact-identity obligation is Proposition R35.3. Beyond that routing there is no further argument — the alias genre working as intended, at every  $n$  at once.  $\square$

**Remark R35.7** (what stays outside the checker).  $(\lambda, B, \theta)$ -existence is the producer's problem, and the classical spectral conditions are its solution theory: when the gain matrix  $\Gamma$  has spectral radius  $\rho(\Gamma) < 1 - \theta$ , the Neumann-series vector  $\lambda := \sum_k (1 - \theta)^{-k} (\Gamma^\top)^k \mathbb{1}$  converges and witnesses  $\Gamma^\top \lambda \leq (1 - \theta)\lambda$ , from which a feasible  $B$  is assembled column by column (under-allocation is repaired by diagonal padding, which only weakens the membership row it feeds). The  $n$ -component ISS small-gain theorem for general networks is Dashkovskiy–Rüffer–Wirth [59]; where that tradition closes a monotone-operator fixpoint argument over the interconnection graph, the certificate form closes the ring identity of Proposition R35.3, and the graph combinatorics survive only as the producer's search space. The signed polynomial contract discipline is the binary section's, unchanged.

| proof step             | formal anchor                                                                                                      |

## Rule 36. PRODUCTLATTICE (admissible rule)

### The rule (Steele metanotation)

as realized in the mechanized development; source row: `rules.toml` — *ProductLattice*. The metanotation statement is typeset by hand for notational quality; its mechanized ground truth is the Lean statement below, extracted from the sources at every build of this book and hash-bound. The rule *roster* is machine-checked (every mechanized rule tag round-trips to exactly one catalogue row); the statement *text* is editorial, checked by eye against the extracted Lean beside it.

$$\frac{B_1 \text{ a certified attracting-block lattice for } \varphi_1 \text{ over } H_1 \quad B_2 \text{ likewise for } \varphi_2 \text{ over } H_2 \quad \text{wires}(H_1) \cap \text{wires}(H_2) = \emptyset}{\{b_1 \times b_2 \mid b_1 \in B_1, b_2 \in B_2\} \text{ (the meet-generators) certified for } \varphi_1 \times \varphi_2 \text{ over } H_1 \sqcup H_2} \text{PRODUCTLATTICE}$$

the displayed family is the list of pairwise-product meet-generators.

the full lattice  $\langle B_1 \times B_2 \rangle_\vee$  (join-closure of the pairwise products) is the paper-strength reading — the bound theorem quantifies over the meet-generators, and the finite-union/boundary-decomposition step remains paper-strength, exactly as the correspondence concedes. Every composite facet sequent is discharged BY CITATION: a composite facet is normal to one factor's axis, its inwardness polynomial IS that factor's facet polynomial with the other factor's coordinates riding along as free box variables (the rider, conjoined onto the premise). Bernstein-wise the composite facet grid is the factor grid tensored with all-ones — a coefficient identity; nothing for a checker to recompute beyond the ordinary BERNCONC recompute pattern. Declared in the baked base theory itself (its first certificate-family rule), not in any separate composition layer.

PRODUCTLATTICE composes at the certificate-*family* level, one judgment up from the sequent rules: given certified attracting-block lattices for two systems over wire-disjoint hypernets, it certifies the join-closure of pairwise products as an attracting-block lattice for the product system over the disjoint union. The geometric fact that powers it: every internal facet of an axis-aligned product block is normal to one factor's axis, so its inwardness polynomial *is* that factor's facet polynomial, with the other factor's coordinates riding along as free box variables. Each composite facet sequent is therefore discharged *by citation*: conclusion kept verbatim, the other factor's box conjoined onto the premise as a rider.

What the checker recomputes: no new Bernstein arithmetic — Bernstein-wise the composite facet grid is the factor grid tensored with all-ones, a coefficient identity, so the per-facet discharge is syntactic identity of the cited conclusion. What remains checked is the citation plumbing itself: wire-disjointness of the two hypernets, factor scopedness, and the rider conjunction on each cited premise.

Wire-disjointness is load-bearing twice. Structurally, the disjoint union of the two hypernets is only well-formed without shared wires (linearity and acyclicity of the union are proven *from* disjointness). Semantically, no single transported facet sequent's validity fails under a shared wire — the weaken lemma conjoins any rider — but the assembled object stops being a product of the factors: the identification of every composite facet with a cited factor facet, the other factor entering only as a rider over fresh coordinates, is proven from disjointness, and with a shared wire the recomputed readout misdescribes the composite. A single shared wire is precisely an interface, and composition along an interface is PROMISE/small-gain territory, not this rule's.

**notes** The soundness statement is dynamics-free — sound for flows and maps alike, because it certifies a *lower bound* family (“these blocks are certified”), never “these are all the attractors”. The completeness reading — that the generated lattice is the whole attractor lattice of the product — is a flows-only theorem of the source literature and lives paper-side; the proof section exhibits the map-dynamics counterexample that forces the fence. No wire tag is allocated yet: soundness lands first, executable checking follows the family-object wire-format work, and the emit path refuses the rule until then.

### Lean statement

**What “discharge by citation” means, stated in the flavor text and bound by the declarations below.** `citeFacet` keeps the cited factor facet's conclusion verbatim and conjoins the rider onto the premise; `prodBlock` assembles a product block's facet list as exactly the two citation families; `prodBlocks` enumerates only the meet-generators of the join-closure — the exponentially many join blocks are never materialized; their sub-facets discharge through the paper-strength boundary decomposition (which selects a factor facet and rider), whose final transport-and-weaken step is the same citation lemmas with smaller riders. A skeptical reader should confirm by eye that no definition below evaluates dynamics anywhere: the rule's semantic content is entirely the transport-and-weaken pair quoted above.

BernsteinLogic.ProductLattice . BlockCert

statement bound

```
-- One certified attracting block, certificate view (the recon's Route-2
shape): its region — the compact axis-aligned box(-union), as the formula
the producer wrote it with — and its internal-facet inwardness sequents
(strict inwardness via non-strict predicates with explicit positive
rational margins; block-hood is elementary for strictly inward box unions,
no combinatorial index data claimed — note §1.1). -/

#### BernsteinLogic.ProductLattice . PProductLatticeData

statement bound

```

/-- Applicability data of the ProductLattice rule – the two factor
families and the side condition. Field-for-field what a checker would
verify: the factor certificates (whose facet-sequent validity enters
`sound_productLattice` as hypotheses, Step-style) and wire-disjointness.
No first-class `RuleTag`/wire constructor in v1 (note §1.4: emission-layer
posture; BINARY.md §6.2 reserves tag 27 for the family-object format
cycle); correspondingly NOT in `v0frag` – like the ReLU family
pre-enactment, soundness lands first and executable checking follows the
format work. -/
structure PProductLatticeData (H1 H2 : Hypernet) where
  disjoint : H1.WireDisjoint H2
  left : CertifiedBlockLattice H1
  right : CertifiedBlockLattice H2

```

#### BernsteinLogic.ProductLattice . Sequent.semanticallyValid\_extend

statement bound

```

/-- TRANSPORT: semantic validity is monotone under hypernet extension –
a sequent valid over H, well-scoped in H, is valid over any H' that
extends H's wire typing and contains H's applications. (For ProductLattice
this is "the factor's certified sign is the composite's inwardness": the
facet polynomial reads only the factor's wires, so the other factor's
coordinates ride along invisibly.) -/

## Correspondence (Steele display ↔ Lean)

**reviewer-certified against the displayed texts** The dictionary below is a reviewer-certified statement of how the mechanized statements above interpret the displayed rule: display metavariable  $\mapsto$  Lean binder, each display hypothesis  $\mapsto$  the premise or side condition carrying it, the display conclusion  $\mapsto$  the goal — with any deliberate difference in width between display and mechanization named outright. Certification is recorded as a hash triple over (the displayed cell, the extracted statement texts, this dictionary's own text); if any of the three changes, this block turns amber until a reviewer re-certifies. The correspondence claim itself remains editorial — reviewer-grade, not machine-checked; its machine-checked successor types each soundness statement against the rule as a structured object, and supersedes this block per rule as it lands.

The one rule of this book whose judgment sits a layer up: the conclusion is not a sequent but a certified *family*, so the  $Ax$  frame applies one level in — per facet sequent.

- $B_1, B_2 \mapsto d.\text{left}, d.\text{right} : \text{CertifiedBlockLattice over } H_1, H_2$ ; “certified for  $\varphi_i$ ”  $\mapsto hL, hR : \text{Valid}$  — every block's every facet sequent semantically valid. Note what does *not* appear: any semiflow. The certified statement is dynamics-free (the note above) — the display's  $\varphi_1 \times \varphi_2$  is the intended reading of the facet sequents, not a consumed hypothesis.
- $\text{wires}(H_1) \cap \text{wires}(H_2) = \emptyset \mapsto d.\text{disjoint} : H_1.\text{WireDisjoint } H_2$ , and the composite carrier  $H_1 \sqcup H_2 \mapsto \text{Hypernet}.\text{disjUnion}$ .
- the displayed conclusion (the meet-generator family certified)  $\mapsto \text{sound\_productLattice}$ , which discharges every facet of every *pairwise product* block ( $\text{prodBlocks}$  — the join-closure's meet-generators) — the displayed family and the bound quantification now coincide. The full join-closure  $\langle B_1 \times B_2 \rangle_\vee$  is the flavor text's paper-strength reading: the joins, never enumerated, discharge facet-by-facet through the standing citation lemmas  $\text{sound\_productLattice\_citeLeft/Right}$  (certified alongside, at *arbitrary* rider), with the boundary decomposition itself paper-strength — no separate join statement is bound.
- with no displayed row: well-scopedness — the factor lattices' facets and regions are confined to their own hypernets ( $\text{facetsScoped}/\text{regionConfined}$  fields of  $\text{CertifiedBlockLattice}$ ), which is what makes transport along the union injection sound; the undisplayed-pack class of the  $\text{PsdCERT}$  evaluability rows.

Width note: the citation lemmas accept *any* rider formula where the rule's conclusion only ever conjoins the other factor's region — wider machinery in the safe direction, and exactly the generality the join-block sub-facets consume.

## Lean verifier receipts

module BernsteinLogic.ProductLattice; bound build 84b7018f79da... (bound from receipt 9ebc3d9af324d1f7, 2026-07-21T04:48:38Z). A receipt records that named checking layers accepted a build: (module, compiled-artifact SHA-256, environment SHA-256, checker layers), minted when the checking gate ran; the store receipts attesting the bound build are listed with the layers each run credited. Nothing here asks the reader to trust the store: every layer is an independently runnable program over the quoted sources — rebuild the module and re-run the checkers to reproduce the verdict. Receipts attesting superseded builds credit no layer and are omitted from this rendering (the count of omissions, if any, is noted below).

| receipt          | minted               | layers                             | status  |
|------------------|----------------------|------------------------------------|---------|
| 224af3a8595b550f | 2026-07-21T01:49:09Z | build+decorrelated                 | current |
| 7187ff3aa085cd58 | 2026-07-21T01:58:41Z | build+decorrelated                 | current |
| 9ebc3d9af324d1f7 | 2026-07-21T04:48:38Z | build+decorrelated                 | current |
| fd5ec354b89369c0 | 2026-07-21T05:28:29Z | build+replay+hardened+decorrelated | current |

7 further receipt(s) in the store attest superseded builds of this module and are omitted from this rendering.

gate-layer coverage of the bound build:

build (lake build (elaboration)) **current**

replay (leanchecker (official kernel replay)) **current**

hardened (safe\_verify (hardened screen)) **current**

decorrelated (lean4export + nanoda (decorrelated kernel)) **current**

**comparator: none** no fixture in the three-implementation comparator harness (compiled / kernel-interpreted / reference-interpreted) exercises this rule.

## HOL4 statement

**NO HOL STATEMENT YET**

The certificate-object stratum of this rule now has HOL twins, with kernel-evaluated transcription receipts, across five ported theories: the certified-block record and the citation constructor, the product-block assembly, the certified block lattice with its wellformedness and validity predicates, the applicability payload record with its wellformedness predicate, the meet-generator enumeration, and the valuation-restriction lemmas the transport argument reads (verified against the scripts this writing; hol-strict clean at the same 2026-07-22 run as the ported entries). What has no HOL twin yet is exactly the rule's semantic content — the transport-and-weaken citation lemmas and the soundness theorem they assemble into (the commentary's own point: nothing in the certificate stratum evaluates dynamics anywhere, so the semantic layer IS the rule). The rule also has no arm in the ported proof-object family and no wire tag on either side. Absent until the citation/soundness stratum ports; the certificate-object groundwork above is in place for that seating.

**HOL verifier receipts****NONE**

no HOL verification receipt exists for this rule.

**Proof**

Genre: admissible rule (tier 2) — a proof-tree-rewriting recipe, at the certificate-family layer: one lattice node unpacks into a family of cited facet sequents. Like PCONSTEXACT, part of the discharge is by reduction to verified machinery rather than to catalogue nodes — the transport step is a semantic monotonicity lemma with no catalogue counterpart, because hypernet extension is invisible to the sequent calculus — and the recipe says so.

**Setting.** A *certified attracting-block lattice* over a hypernet  $H$  (the `CertifiedBlockLattice` structure quoted above) is a finite family of blocks — each a region box formula plus its internal-facet inwardness sequents — carrying explicit index-level lattice structure and wire confinement; the family is *valid* when every facet sequent is semantically valid over  $H$ . The rule's premises: valid families  $B_1$  over  $H_1$  and  $B_2$  over  $H_2$ , and wire-disjointness  $\text{wires}(H_1) \cap \text{wires}(H_2) = \emptyset$ . Conclusion: the join-closure  $\langle B_1 \times B_2 \rangle_\vee$  is certified over the disjoint union  $H_1 \sqcup H_2$ .

**Recipe R36.1** (the `PRODUCTLATTICE` instance — one node, a citation family). The rewrite replaces the lattice node by one derivation fragment *per facet of per product block*, each of the same two-move shape:

$$\frac{s_0 \triangleright \text{a factor facet sequent (cited sub-proof)}}{\langle \text{pre}(s_0) \wedge \text{rider}, \text{post}(s_0) \rangle \text{ over } H_1 \sqcup H_2} \text{CITE}$$

where the rider is the *other* factor's box. The conclusion is kept verbatim — the polynomial and predicate of the cited facet, unchanged — because a composite facet of an axis-aligned product is normal to one factor's axis: its inwardness polynomial *is* that factor's, the other factor's coordinates riding along as free box variables. Only the meet-generators  $\{b_1 \times b_2\}$  are enumerated ( $O(|B_1| \cdot |B_2|)$  blocks,  $O(|B_1| + |B_2|)$  distinct cited factor sub-proofs, each reused across its products with varying riders); the join-closure's remaining elements — exponentially many — are never materialized. They discharge by the same mechanism: a boundary point of a finite union of axis-aligned blocks lies on the boundary of some member containing it (member interiors are interior to the union), so a union block's boundary decomposes into sub-facets, each a subset of some generator's facet and hence again normal to one factor's axis; inwardness for the member implies inwardness for the union (monotonicity under  $\sqsubseteq$ ), so the sub-facet's sequent is the same factor citation with its premise further constrained to the exposed portion — and the citation lemmas accept these further-constrained premises because they accept an *arbitrary* rider.

**Lemma R36.2** (transport: validity is monotone under hypernet extension). *Let  $H'$  extend  $H$ 's wire typing and contain  $H$ 's applications, and let  $s$  be semantically valid over  $H$  and well-scoped in  $H$ . Then  $s$  is semantically valid over  $H'$ .*

*Proof.* An admissible valuation  $\sigma$  of  $H'$  restricts to a valuation of  $H$  (read each  $H$ -typed wire through the extension), and the restriction is admissible: every entry a per-application semantic predicate reads is at a port wire, typed in  $H$  by type consistency, where the restriction agrees with  $\sigma$  by construction. Formulas whose free wires are  $H$ -typed therefore evaluate identically under  $\sigma$  and its restriction — by induction on terms and formulas, the only base case being a wire read, which is where well-scopedness is consumed. So from  $\sigma \models \text{pre}(s)$ : the restriction satisfies  $\text{pre}(s)$ , validity over  $H$  gives the restriction satisfies  $\text{post}(s)$ , and evaluation-agreement carries it back to  $\sigma$ . This is `Sequent.semanticallyValid_extend`; the well-scopedness hypothesis is not decoration — a sequent reading a wire *untyped* in  $H$  evaluates that read differently in an extension that types it, and the induction's base case fails exactly there.  $\square$

**Lemma R36.3** (weaken, standalone). *If  $\langle \text{pre}, \text{post} \rangle$  is semantically valid over  $H$ , so is  $\langle \text{pre} \wedge \text{extra}, \text{post} \rangle$ , for any formula  $\text{extra}$ .*

*Proof.* Project the premise (`Sequent.semanticallyValid_weaken`). The rider needs no side condition — in particular it may mention wires the cited factor has never heard of, which is the whole point.  $\square$

**Proposition R36.4** (soundness of `PRODUCTLATTICE`). *Given valid families over wire-disjoint hypernets, every facet sequent of every product block is semantically valid over  $H_1 \sqcup H_2$ .*

*Proof.* A product block’s facet list is, by construction (`prodBlock`), the left factor’s facets cited with the right factor’s region as rider, concatenated with the symmetric family. For a left-cited facet: the disjoint union extends  $H_1$ ’s wire typing and contains its applications (disjointness makes the union’s linearity, acyclicity, and type consistency inherit from the factors — this is where the side condition does structural work), so Lemma R36.2 transports the factor’s validity to the union, and Lemma R36.3 conjoins the rider. Symmetrically on the right. That is the entire proof (`sound_productLattice`, through the two standing citation lemmas `sound_productLattice_citeLeft/citeRight`). For the un-enumerated join blocks’ sub-facets the same two lemmas supply the per-generator transport and arbitrary-rider steps, with the exposure constraints as riders — but the join-closure extension itself (the boundary decomposition of Recipe R36.1’s argument) is paper-strength: no bound declaration represents finite unions, their boundary decomposition, or the union-inwardness step, and the mechanized theorem quantifies over the generator blocks only.  $\square$

*Remark R36.5* (why wire-disjointness is not decoration). With a shared wire the recipe fails twice. Structurally, the disjoint union is no longer well-formed as built (linearity of the concatenated application lists is proven *from* disjointness). Semantically, no single transported sequent’s validity would fail — Lemma R36.3 conjoins *any* rider, shared wires included — but the assembled *readout* would misdescribe the composite: the identification of every product-block facet with a cited factor facet (the other factor entering only as a rider) is proven from disjointness, and with a shared wire the built object is simply not a product of the factors. A single shared wire is precisely an *interface*, and composition along an interface is PROMISE/small-gain territory — the rule’s applicability condition is the boundary between the two composition regimes, not a technicality.

*Remark R36.6* (the completeness fence: flows only, and the map counterexample). Proposition R36.4 is dynamics-free — no premise mentions a flow or a map, so the rule is sound for both. What is *flows-only* is the completeness reading from the source literature [133]: for flows, the attractor lattice of a product is the coproduct of the factors’ lattices, so the generated family is everything. For maps it is not: with  $f(x) = -\tanh(2x)$  on  $[-p, p]$  (where  $\tanh(2p) = p$ ), the factor attractor lattice is  $\{\emptyset, P, X\}$  with  $P = \{p, -p\}$ , yet  $f \times f$  has the phase-locked period-two attractors  $\{(p, p), (-p, -p)\}$  and  $\{(p, -p), (-p, p)\}$  — neither generated by factor attractors; the coproduct is a proper sublattice. (The arithmetic:  $\tanh(2x)$  leaves the diagonal with slope 2, so a fixed point  $p \approx 0.96$  of  $\tanh(2p) = p$  exists; 0 repels,  $|f'(0)| = 2$ ; each product two-cycle attracts,  $(f^2)'(\pm p) = 4(1 - p^2)^2 < 1$ ; and that the factor lattice has nothing beyond  $\emptyset, P, X$  is the source example’s own analysis [133].) The Lean statement is shaped so this cannot overreach: it certifies a lower bound family, and any decomposition-level readout from a map instance must be stated as “at least this structure,” never “exactly this.”

## 15.5 Judgment Structure and Batteries

### Rule 37. QSATFROMREGION (alias for PCONSTEXACT)

#### The rule (Steele metanotation)

as realized in the mechanized development; source row: QTSL-rules.toml — *QSatFromRegion*. The metanotation statement is typeset by hand for notational quality; its mechanized ground truth is the Lean statement below, extracted from the sources at every build of this book and hash-bound. The rule *roster* is machine-checked (every mechanized rule tag round-trips to exactly one catalogue row); the statement *text* is editorial, checked by eye against the extracted Lean beside it.

$$\frac{\text{child} : \text{QRegionSat}(\varphi, R) \quad \text{eval} \vdash x_0 \in R \text{ (BL leaf; sublevel} \rightarrow \text{PCONSTEXACT, box} \rightarrow \text{registry interval check)} \quad \text{Sinit}(\varphi) \in s.\forall}{\mathcal{M} \models s}$$

QSATFROMREGION is the extension theory's closing move: it turns a region-level certificate into the root satisfaction verdict. The workhorse judgment of the extension page concludes region-level facts — every point of a region  $R$  satisfies the formula  $\varphi$ , with  $R$  under-approximating the formula's denotation — and this rule is the single bridge from that shape to the top-level claim  $\mathcal{M} \models s$ : cite the child, check that the specification's initial point  $x_0$  lies in  $R$  by exact rational arithmetic, and require that the warranted safety component of the specification is the initial-state injection  $\text{Sinit}(\varphi)$  of the child's formula. A producer uses it exactly once per initialized certificate, as the last row.

What the checker recomputes: the membership leaf — for a sublevel atom  $\{x : V(x) \leq y\}$ , exact substitution of  $x_0$  into  $V$  and one closed comparison, which is precisely the ground-fact rule PCONSTEXACT's own check; for a box atom, per-coordinate containment recomputed by the checker's side-condition registry — and the component tie: the warrant row names which safety component it warrants, anything other than the  $\text{Sinit}$  image of the child's formula refuses at load (a menu of one), and that the named component is among the specification's consumed components is admission conformance.

What would break without each hypothesis: drop the child and  $R$  is an arbitrary set nobody certified — the conclusion is unmoored from any proof; drop the eval leaf and  $x_0$  may lie outside  $R$ , so the child's universal never instantiates (a certificate could certify a region the system never starts in); drop the component tie and a certificate about some subformula — or an unrelated formula — could claim a component it never certified.

**notes** The soundness content is one line — instantiation of the child's universal at  $x_0$  — which is why the rule prices as an alias even though it has two premise fields: the child is a judgment *citation* (an edge under the tower discipline, the PROOFWELLFORMEDNESS section), and the sole derivation node the respelling produces is the PCONSTEXACT leaf. Mechanization state, plainly: the bound statements below are that one line and its assembly. `sound_QSatFromRegion` (module `BernsteinLogicAux.QtslAliases`) is the instantiation itself, generic in the satisfaction predicate and profile-free — axiom-free, even: the kernel certifies it depends on no axioms at all — and `sound_QSatFromRegion_sublevel` composes it over the exact-Q membership leaf (the `ROOTEval` identities, this page), which is the sole derivation node named above. The payload-level elaborator is bound beside them (module `BernsteinLogic.QtslElaborators`, the batch template's unpack made concrete): `qsatFromRegionElab` takes the rule payload to the one PCONSTEXACT payload — an inhabitant of the target's own payload type, comparator confinement discharged at elaboration — with `qsatFromRegionElab_sound` the factoring through `sound_pConstExact` and `qsatFromRegionElab_sat` the judgment-level composition over the elaborated leaf; the semantic content carries no profile residue, so the entry carries no conditional flag. Inherited flag, travelling with the alias: the target excludes the  $\neq$  comparator from its admissible set (a second-soundness-invariant exclusion, unpacked in the target's section); the membership leaf uses  $\leq$ , and any port must preserve the exclusion.

#### Lean statement

`BernsteinLogicAux.QtslAliases . sound_QSatFromRegion`

statement bound

```
/-- **`sound_QSatFromRegion`** (QTSL-rules.toml row `QSatFromRegion`; the
catalogue's "Soundness: one line – instantiation of the universal"): the
child certificate concludes region-level satisfaction (`R` under-approximates
the truth set: every point of `R` satisfies), the eval leaf places the
specification's initial point in `R`, and the root claim follows by
instantiation. Generic in the satisfaction predicate: for the probabilistic
judgments the extension page concludes, `sat x` reads as the concluded
bound at start `x` (e.g. `sound_QSafetyBattery`'s conclusion), and the rule
is profile-free. The root tie `s.root = φ` is a syntactic side condition
recomputed by the checker; it selects *which* predicate this lemma is
instantiated at, and carries no semantic content of its own. -/
theorem sound_QSatFromRegion {X : Type*} {R : Set X} {sat : X → Prop} {x₀ : X}
  (hchild : ∀ x ∈ R, sat x) (heval : x₀ ∈ R) : sat x₀
```

BernsteinLogicAux.QtslAliases . sound\_QSatFromRegion\_sublevel

statement bound

```

/-- **`QSatFromRegion` assembled over its `RootEval` leaf, sublevel shape**:
the child's region-level universal on the cast sublevel atom, instantiated
at the cast initial point through the exact-Q evaluation – the sole
derivation node the respelling produces, composed. -/
theorem sound_QSatFromRegion_sublevel {σ : Type*} {sat : (σ → ℝ) → Prop}
  {P : MvPolynomial σ ℚ} {thr : ℚ} {xq : σ → ℚ}
  (hchild : ∀ x ∈ {x : σ → ℝ |
    MvPolynomial.eval x (MvPolynomial.map (Rat.castHom ℝ) P) ≤ (thr : ℝ)}, sat x)
  (heval : MvPolynomial.eval xq P ≤ thr) :
  sat (fun i => (xq i : ℝ))

```

**The payload-level elaborator, displayed whole.** The unpack builds the target's payload from the rule's wire data — the eval field *is* the `RootEval` leaf (that section binds the closed-term builder and the wire-level exactness identity it rides).

BernsteinLogic.QtslElaborators . qsatFromRegionElab\_sound

statement bound

```

/-- The factoring, BL face – through `sound_pConstExact`, as the amber
box demanded. -/
theorem qsatFromRegionElab_sound {H : Hypernet} {seq : Sequent}
  {x0 : Nat → Rat} {V : Poly} {thr : Rat}
  (hEval : (rootEvalFormula x0 V thr).evalClosed = some true)
  (hpost : seq.post = rootEvalFormula x0 V thr) :
  seq.semanticallyValid H

```

BernsteinLogic.QtslElaborators . qsatFromRegionElab\_sat

statement bound

```

/-- The judgement-level composition over the elaborated leaf
(`prop:qsr-sound` at the wire): instantiation of the child's universal
at  $x_0$ , the membership hypothesis supplied by the checked leaf through
the  $\mathbb{Q}$ -face exactness identity. `sound_QSatFromRegion` is generic in the
satisfaction predicate and the carrier, so the composition consumes the
bound lemma verbatim – sound_A = (instantiation) ◦ (elaborated leaf). -/
theorem qsatFromRegionElab_sat {x0 : Nat → Rat} {V : Poly} {thr : Rat}
  {sat : (Nat → Rat) → Prop}
  (hchild : ∀ x ∈ {x : Nat → Rat | Poly.eval x V ≤ thr}, sat x)
  (hEval : (rootEvalFormula x0 V thr).evalClosed = some true) :
  sat x0

```

BernsteinLogic.QtslElaborators . qsatFromRegionElab

definition bound

```

/-- **The QSatFromRegion payload elaborator**, sublevel case: the
rule's wire payload elaborates to exactly the RootEval leaf's payload –
the leaf-level respelling has its own row (`RootEval`), and this rule's
eval field IS that leaf (the consumption-site anchor of the RootEval
section). -/
def qsatFromRegionElab (H : Hypernet) (seq : Sequent) (x0 : Nat → Rat)
  (V : Poly) (thr : Rat)
  (hEval : (rootEvalFormula x0 V thr).evalClosed = some true)
  (hpost : seq.post = rootEvalFormula x0 V thr) :
  PConstExactData H seq :=
  rootEvalElab H seq x0 V thr hEval hpost

```

## Correspondence (Steele display ↔ Lean)

**reviewer-certified against the displayed texts** The dictionary below is a reviewer-certified statement of how the mechanized statements above interpret the displayed rule: display metavariable  $\mapsto$  Lean binder, each display hypothesis  $\mapsto$  the premise or side condition carrying it, the display conclusion  $\mapsto$  the goal — with any deliberate difference in width between display and mechanization named outright. Certification is recorded as a hash triple over (the displayed cell, the extracted statement texts, this dictionary's own text); if any of the three changes, this block turns amber until a reviewer re-certifies. The correspondence claim itself remains editorial — reviewer-grade, not machine-checked; its machine-checked successor types each soundness statement against the rule as a structured object, and supersedes this block per rule as it lands.

The displayed premises map onto `sound_QSatFromRegion` verbatim: the child  $\mathbb{Q}$ RegionSat( $\varphi, R$ )  $\mapsto$  `hchild : ∀ x ∈ R, sat x` (region-level satisfaction, compiled); the eval leaf  $\vdash x_0 \in R \mapsto$  `heval : x_0 ∈ R`; the conclusion  $\mathcal{M} \models s \mapsto$  `sat x_0` — universal instantiation, one line, axiom-free. The component tie ( $\text{SInit}(\varphi) \in s.\forall$ , the refuse-mode warrant naming) has deliberately no Lean

counterpart: it is the syntactic side condition that selects *which* predicate `sat` the lemma is instantiated at, recomputed by the checker, carrying no semantic content — the statement's docstring says exactly this. `sound_QSatFromRegion_sublevel` is the assembled form over the exact- $\mathbb{Q}$  `RootEval` leaf: child universal on the cast sublevel atom + exact- $\mathbb{Q}$  evaluation `heval : MvPolynomial.eval xq P ≤ thr ⇒ satisfaction at the cast initial point` — the sole derivation node the respelling produces, composed. Width note: `sat : X → Prop` is generic — probabilistic conclusions read `sat x` as the concluded bound at start `x`, so the alias is profile-free by binder shape; wider than any single displayed instantiation, safe direction.

## Lean verifier receipts

module `BernsteinLogicAux.QtslAliases`; bound build 570599779c29... (bound from receipt 5a60f4d01fd81ac5, 2026-07-21T05:39:02Z). A receipt records that named checking layers accepted a build: (module, compiled-artifact SHA-256, environment SHA-256, checker layers), minted when the checking gate ran; the store receipts attesting the bound build are listed with the layers each run credited. Nothing here asks the reader to trust the store: every layer is an independently runnable program over the quoted sources — rebuild the module and re-run the checkers to reproduce the verdict. Receipts attesting superseded builds credit no layer and are omitted from this rendering (the count of omissions, if any, is noted below).

| receipt          | minted               | layers                             | status  |
|------------------|----------------------|------------------------------------|---------|
| 0a3819a978e31127 | 2026-07-21T04:51:36Z | build+decorrelated                 | current |
| 0bb1074df705d863 | 2026-07-21T05:21:58Z | build+decorrelated                 | current |
| 5a60f4d01fd81ac5 | 2026-07-21T05:39:02Z | build+replay+hardened+decorrelated | current |

11 further receipt(s) in the store attest superseded builds of this module and are omitted from this rendering.

module `BernsteinLogic.QtslElaborators`; bound build 0205ec213b91... (hashed from the built olean at bind time). A receipt records that named checking layers accepted a build: (module, compiled-artifact SHA-256, environment SHA-256, checker layers), minted when the checking gate ran; the store receipts attesting the bound build are listed with the layers each run credited. Nothing here asks the reader to trust the store: every layer is an independently runnable program over the quoted sources — rebuild the module and re-run the checkers to reproduce the verdict. Receipts attesting superseded builds credit no layer and are omitted from this rendering (the count of omissions, if any, is noted below).

| receipt          | minted               | layers             | status  |
|------------------|----------------------|--------------------|---------|
| a237f4cff27cb15a | 2026-07-22T10:06:47Z | build+decorrelated | current |

### gate-layer coverage of the bound build:

build (lake build (elaboration)) current  
 replay (leanchecker (official kernel replay)) current  
 hardened (safe\_verify (hardened screen)) current  
 decorrelated (lean4export + nanoda (decorrelated kernel)) current

**comparator: none** no fixture in the three-implementation comparator harness (compiled / kernel-interpreted / reference-interpreted) exercises this rule.

## HOL4 statement

### NO HOL STATEMENT YET

The HOL4 development's object is the base calculus's wire-format checker (theory `bern_catalogue` ports the base catalogue's check-function cone); no HOL development of the extension theory exists, so there is no HOL statement for any extension rule to bind. Absent rather than out-of-scope: the bridge's baked realization is the extension theory's warrant seam (`qsat_warrant`), so a future HOL port of an extension-theory checker would state it. The one leaf the alias adds checks through the base ground-fact rule `PConstExact`, whose own HOL statement is not yet writable either (it postdates the HOL4 port and its wire tag is unallocated — see that rule's section).

## HOL verifier receipts

### NONE

no HOL verification receipt exists for this rule.

## Proof

Genre: alias rule (tier 3) — a respelling template: the 1→1 unpack, the filled-in target application, the payload-transport table, the exactness identity, and the soundness corollary through the target's lemma. Two riders. First, the tier criterion counts derivation *nodes*, not premise fields: this rule has two premise fields, but the child is a judgment *citation* — an edge under the tower discipline (the `PROOFWELLFORMEDNESS` section), not a node any unpack must produce — so the rule's proof content per instance is at most one node: in the sublevel branch, the single `PConstExact`

application discharging its membership leaf; in the box branch, no node at all (the leaf is registry recomputation). The child instantiation and the component tie are definitional transports along edges, not nodes any unpack produces — that, and nothing stronger, is the sense in which the rule is an alias. Second, the semantic composition is mechanized and bound in the entry, and so — now that the extension certificate schema exists — is the payload-level elaborator (the batch template's unpack, at the wire level; the remark below names the bound functions).

**Recipe R37.1** (the alias template, one extends-edge up). An alias at the satisfaction level is warranted by a  $1 \rightarrow 1$  respelling into a single application of a target rule, with judgment citations transported as *edges* and the concluded judgment recovered definitionally from the cited child. Here the target is the base calculus's ground-fact rule  $\text{PCONSTEXACT}$ ; the one new node is the membership leaf; and the  $\models$ -level conclusion is an instantiation of the child's universal (Proposition R37.4), not a derived fact needing catalogue structure.

**Recipe R37.2** (the filled-in application). The rule's fields: a child judgment  $\text{child} : \text{QRegionSat}(\varphi, R)$  — every point of  $R$  satisfies  $\varphi$ , with  $R$  under-approximating the formula's denotation — a membership leaf eval, and the component tie  $\text{SInit}(\varphi) \in s.\forall$  (the warranted safety component is the initial-state injection of the child's formula — the record carries component lists, not a single root, and the warrant row names its component). For a sublevel region atom  $R = \{x : V(x) \leq y\}$ , with  $V$  a polynomial over  $\mathbb{Q}$  and  $x_0$  the specification's rational initial point, the eval leaf is the  $\text{PCONSTEXACT}$  node

$$\frac{V(x_0) \leq y \text{ holds under exact evaluation in } \mathbb{Q}}{\Phi \vdash V(x_0) \leq y} \text{PCONSTEXACT}$$

with arbitrary premise  $\Phi$ , as the target licenses.  $V(x_0)$  is the closed term obtained by exact substitution of  $x_0$ 's coordinates — wire-free, so the target's verified evaluator decides it, with comparator  $\leq$  inside the target's admissible set. The leaf-level respelling has its own row on this page (ROOTEVAL), whose section carries the transport and exactness detail; this section carries the judgment-level composition. For a *box* atom the leaf is not a  $\text{PCONSTEXACT}$  node: per-coordinate interval containment is recomputed directly by the checker's side-condition registry — the alias reading covers the sublevel branch, and the box branch is stated here so the respelling never overclaims.

**Recipe R37.3** (payload transport — field for field).

| $\text{QSATFROMREGION}$ field                       | destination                                                         |
|-----------------------------------------------------|---------------------------------------------------------------------|
| child                                               | not transported — a judgment citation (edge; the tower discipline)  |
| eval                                                | the $\text{PCONSTEXACT}$ payload: closed comparison $V(x_0) \leq y$ |
| component tie $\text{SInit}(\varphi) \in s.\forall$ | the concluded judgment's formula                                    |
| concluded $\mathcal{M} \models s$                   | instantiation of the child's universal at $x_0$                     |

**Proposition R37.4** (the instantiation identity). *If  $R \subseteq \{x : \mathcal{M}, x \models \varphi\}$  and  $x_0 \in R$ , then  $\mathcal{M}, x_0 \models \varphi$ ; with the component tie, this is  $\mathcal{M} \models s$ . Moreover, for the sublevel atom the membership hypothesis is exactly the checked leaf, as an identity of exact rationals:*

$$x_0 \in R \iff V(x_0) \leq y,$$

*because substituting a rational point into a rational polynomial evaluates with no rounding — the checker's true verdict is membership, not an approximation to it (the ROOTEVAL section proves this as its exactness identity).*

*Proof.* Instantiate the universal at  $x_0$ ; with the component tie the instance is  $\mathcal{M} \models s$ . For the moreover clause, two equivalences compose:  $x_0 \in R \iff V(x_0) \leq y$  is the sublevel region's membership predicate read at  $x_0$  — a definition, not a computation — and the identification of the checker's true verdict with that exact inequality is the ROOTEVAL exactness identity, cited rather than re-proved. The instantiation is the rule's entire own content — one node's worth, which is why it prices as an alias.  $\square$

**Proposition R37.5** (soundness corollary). *In the sublevel branch,  $\text{sound}_{\text{QSATFROMREGION}} = \text{sound\_pConstExact}$  (applied to the eval leaf) ; (instantiation at  $x_0$ ); in the box branch the recomputed containment supplies the membership fact and the same instantiation finishes. In both branches the child's validity is supplied by the induction hypothesis of the tower discipline's induction (PROOFWELLFORMEDNESS section).*

*Proof.* Sublevel branch:  $\text{sound\_pConstExact}$  (the target's kernel-verified lemma, quoted in the  $\text{PCONSTEXACT}$  section) turns the true evaluation into the validity of  $V(x_0) \leq y$ ; Proposition R37.4 finishes. Box branch: the recomputed containment plays the leaf's role — per-coordinate comparison of exact rationals, the box face of the same no-rounding exactness the ROOTEVAL section proves for sublevel leaves, so the recompute's verdict is membership itself; Proposition R37.4's instantiation, which never asked how membership was obtained, finishes identically.  $\square$

**Remark R37.6** (the payload-level elaborator, mechanized). The *semantic* composition above is bound in the entry:  $\text{sound\_QSATFROMREGION}$  is the instantiation (axiom-free), and  $\text{sound\_QSATFROMREGION\_sublevel}$  is Proposition R37.5's statement over the exact- $\mathbb{Q}$  leaf (the ROOTEVAL identities). The payload-level elaborator — previously this page's one absent artefact, held back until the extension certificate schema existed — is bound with it:  $\text{qsatFromRegionElab}$  (module  $\text{BernsteinLogic.QtsLElaborators}$ ) takes the rule's wire payload to (in the sublevel case) exactly the one  $\text{PCONSTEXACT}$  payload of Recipe R37.3, as an inhabitant of the target's own payload type — the comparator confinement discharged at elaboration, once — with  $\text{qsatFromRegionElab\_sound}$  the factoring through  $\text{sound\_pConstExact}$  and  $\text{qsatFromRegionElab\_sat}$  the judgment-level composition over the elaborated leaf, the checker's verdict entering as membership through the wire-level exactness identity  $\text{rootEvalFormula\_true\_iff}$  (the  $\mathbb{Q}$  face of the ROOTEVAL identities). The box branch remains checker-side registry recompute, by design — nothing to elaborate.

**Remark R37.7** (the inherited comparator confinement).  $\text{PCONSTEXACT}$  excludes one comparator ( $\neq$ ) from its admissible set, for reasons of a second soundness invariant unpacked in that rule's section. The membership leaf uses  $\leq$  only — comfortably inside — but any port or mechanization of this rule must *preserve* the exclusion rather than re-derive the comparator set from the semantic lemma alone; the flag travels with the alias.

| proof step                              | formal anchor                                                                                                                      |

## Rule 38. QGUARDINTRO (core rule)

### The rule (Steele metanotation)

as realized in the mechanized development; source row: QTSL-rules.toml — *QGuardIntro*. The metanotation statement is typeset by hand for notational quality; its mechanized ground truth is the Lean statement below, extracted from the sources at every build of this book and hash-bound. The rule *roster* is machine-checked (every mechanized rule tag round-trips to exactly one catalogue row); the statement *text* is editorial, checked by eye against the extracted Lean beside it.

$$\frac{\text{child} : \text{QRegionSat}(\varphi, R) \quad \text{SInit}(\varphi) \in s. \forall}{\mathcal{M} \models \text{Guard}(R, s)}$$

QGUARDINTRO is implication introduction at the judgment stratum: from a region-level certificate alone — every state of  $R$  satisfies  $\varphi$  — it concludes the *guarded* claim  $\mathcal{M} \models \text{Guard}(R, s)$ , with no initial-membership premise anywhere. The hypothesis that the unguarded route discharges at the ground seam ( $X_0 \subseteq R$ , checked by exact rational arithmetic) is instead discharged *into the specification*: a guarded specification demands its body's guarantee only from initial states inside  $R$  and promises nothing off-region. The guard region imports the certificate-side region grammar (sublevel, box, affine) into the specification record at exactly one slot; the record still binds no model and fixes no initial condition — the guard is a predicate *on* the subject's initial data, not initial data.

What the checker recomputes: nothing beyond the child's own obligations — that is the point. The two ties are load-time conformance, not computation: the guarded warrant row names its safety component, and anything other than the initial-state injection of the warrant's formula refuses at load (a menu of one); the guard region stored on the record is derived from the warrant row itself (store-and-check: a disagreeing producer row is a second region on a one-region slot, refused at conformance).

What would break without each hypothesis: drop the child and the guarded claim is unmoored from any proof; drop the component tie and a certificate about an unrelated formula could claim the guarded specification; drop the disjointness from the unguarded warrant relation and the initial-membership demand would fire on a guarded introduction — exactly the hypothesis the former exists to internalize.

**notes** The semantics is *pointwise* over the credal stack: a behavior object satisfies  $\text{Guard}(R, s)$  iff every admitted law whose initial marginal is supported in  $\llbracket R \rrbracket$  meets  $s$ 's demand — at demonic-box initial data this is exactly conditioning the belief evaluation on initial membership. Pointwise is *strictly stronger* than the blanket conditional (“if all of  $X_0$  lies in  $R$  then...”), and the strictness is a theorem, not a taste: the blanket reading would vacuously discharge any guard the initial set merely straddles. The class algebra stays a complement-free distributive lattice — the guard's antecedent is a ground condition on system data, not a behavior class, which is why the conditional lives at the record stratum and no formula-level implication former exists or is introduced.

### Theory rows (geolog)

The rule's certificate content as it is declared in the geolog theory the checker loads — payload schema, side-condition demands, and axiom rows, quoted from the theory source at every build of this catalogue (a stale quotation cannot exist). Axiom modes: chase = the engine derives; report = a violation is a loud judgment; refuse = a violation gates admission. Side-condition relations are discharged by bounded evaluation at the engine's ground seam, never by derivation.

The baked realization: the guard slot on the specification record, the guarded-route warrant relation (disjoint-by-relation from the unguarded one, so the initial-membership axiom structurally never fires on a guarded introduction), and the ties.

## Lean statement

The guarded denotation and the introduction's soundness, displayed whole. GuardSat is the pointwise reading; the strictness witness against the blanket conditional and the wrong-region countermodel bind beside the soundness statements.

QtslAux.QGuard.sound\_QGuardIntro

statement bound

```

/-- Soundness of the introduction rule: a region warrant – the body's
demand holds from every state of `R` – yields the guarded claim with no
initial-membership premise, for any initial set. The membership hypothesis
that region-warranted satisfaction discharges at the ground seam is here
discharged into the former (implication introduction). -/
theorem sound_QGuardIntro {init R : Set X} {sat : X → Prop}
  (hchild : ∀ x ∈ R, sat x) : GuardSat init R sat

```

QtslAux.QGuard.sound\_QGuardIntro\_sublevel

statement bound

```

/-- The rational-sublevel guard (a certificate family's sublevel set at an
exact-rational threshold, single-piece form): a warrant on the real
sublevel set of the coefficient-cast polynomial yields the guarded claim
with that sublevel set in the guard slot, for any initial set. -/
theorem sound_QGuardIntro_sublevel {σ : Type*} {init : Set (σ → ℝ)}
  {sat : (σ → ℝ) → Prop} {P : MvPolynomial σ ℚ} {thr : ℚ}
  (hchild : ∀ x ∈ {x : σ → ℝ |
    MvPolynomial.eval x (MvPolynomial.map (Rat.castHom ℝ) P) ≤ (thr : ℝ)},
    sat x) :
  GuardSat init
  {x : σ → ℝ |
    MvPolynomial.eval x (MvPolynomial.map (Rat.castHom ℝ) P) ≤ (thr : ℝ)}
  sat

```

QtslAux.QGuard.sound\_QGuardIntro\_prob

statement bound

```

/-- Kernel-form corollary in the battery idiom: a per-initial-state
probability floor warranted on the region yields the guarded floor. -/
theorem sound_QGuardIntro_prob [MeasurableSpace X] {init R : Set X}
  {μ : X → Measure (ℕ → X)} {p : ENNReal} {A : Set (ℕ → X)}
  (hchild : ∀ x ∈ R, p ≤ μ x A) :
  GuardSat init R fun x => p ≤ μ x A

```

QtslAux.QGuard.exists\_blanket\_not\_guardSat

statement bound

```

/-- Strictness witness for the semantics adjudication, and the permanent
twin of the dropped-membership mutant: the blanket reading does not imply
the pointwise one. On `Bool` with the full initial set, guard region
`{true}`, and an everywhere-false demand, the blanket conditional holds
vacuously (the initial set is not contained in the region) while the
pointwise guard is refuted at `true`. A blanket semantics would license
claims the pointwise semantics rejects; the former adopts the pointwise
reading. -/
theorem exists_blanket_not_guardSat :
  ∃ (init R : Set Bool) (sat : Bool → Prop),
    GuardSatBlanket init R sat ∧ ¬ GuardSat init R sat

```

QtslAux.QGuard.exists\_not\_guardSat\_wrong\_region

statement bound

```

/-- Wrong-region countermodel (the permanent twin of the region-substitution
mutant): a warrant on one region does not license a guard on an unrelated
one – an everywhere-false demand is vacuously warranted on the empty

```

```
region, and the guard on the full region is refuted. -/
theorem exists_not_guardSat_wrong_region :
  ∃ (init R R' : Set Bool) (sat : Bool → Prop),
    (∀ x ∈ R, sat x) ∧ ¬ GuardSat init R' sat
```

QtslAux.QGuard.GuardSat

definition bound

```
-- The guarded-satisfaction denotation, pointwise (demonic-initial-set)
form: every admitted initial point inside the guard region meets the body's
demand; initial points outside the region are unconstrained. -/
def GuardSat (init R : Set X) (sat : X → Prop) : Prop :=
  ∀ x₀ ∈ init, x₀ ∈ R → sat x₀
```

## Correspondence (Steele display ↔ Lean)

**reviewer-certified against the displayed texts** The dictionary below is a reviewer-certified statement of how the mechanized statements above interpret the displayed rule: display metavariable  $\mapsto$  Lean binder, each display hypothesis  $\mapsto$  the premise or side condition carrying it, the display conclusion  $\mapsto$  the goal — with any deliberate difference in width between display and mechanization named outright. Certification is recorded as a hash triple over (the displayed cell, the extracted statement texts, this dictionary's own text); if any of the three changes, this block turns amber until a reviewer re-certifies. The correspondence claim itself remains editorial — reviewer-grade, not machine-checked; its machine-checked successor types each soundness statement against the rule as a structured object, and supersedes this block per rule as it lands.

The display maps onto `sound_QGuardIntro` verbatim: the child  $\text{QRegionSat}(\varphi, R) \mapsto h : \forall x \in R, \text{sat } x$ ; the conclusion  $\mathcal{M} \models \text{Guard}(R, s) \mapsto \text{GuardSat init } R \text{ sat}$  (pointwise: every admitted initial point inside  $R$  meets the body's demand), generic in the initial set `init` — the rule is sound for *any* initial data, which is what “no membership premise” means formally. The component tie  $(\text{SInit}(\varphi) \in s.\forall)$  has deliberately no Lean counterpart: it is the load-time refusal selecting *which* predicate `sat` the lemma is instantiated at. Width note: `sat : X → Prop` is generic, so probabilistic bodies read `sat x` as the concluded bound at start  $x$  — wider than any single displayed instantiation, safe direction. The specializations bind beside it: `sublevel-atom` guards over exact- $\mathbb{Q}$  polynomial evaluation (`sound_QGuardIntro_sublevel`, `guard_eval_sublevel`) and the probability-threshold body form (`sound_QGuardIntro_prob`).

## Lean verifier receipts

module QtslAux.QGuard; bound build 3eb84fb9b559... (bound from receipt bd99b3a9109c4daf, 2026-07-28T18:45:47Z). A receipt records that named checking layers accepted a build: (module, compiled-artifact SHA-256, environment SHA-256, checker layers), minted when the checking gate ran; the store receipts attesting the bound build are listed with the layers each run credited. Nothing here asks the reader to trust the store: every layer is an independently runnable program over the quoted sources — rebuild the module and re-run the checkers to reproduce the verdict. Receipts attesting superseded builds credit no layer and are omitted from this rendering (the count of omissions, if any, is noted below).

| receipt          | minted               | layers             | status  |
|------------------|----------------------|--------------------|---------|
| bd99b3a9109c4daf | 2026-07-28T18:45:47Z | build+decorrelated | current |

gate-layer coverage of the bound build:

build (lake build (elaboration)) **current**

replay (leanchecker (official kernel replay)) **none**

hardened (safe\_verify (hardened screen)) **none**

decorrelated (lean4export + nanoda (decorrelated kernel)) **current**

**comparator:** **none** no fixture in the three-implementation comparator harness (compiled / kernel-interpreted / reference-interpreted) exercises this rule.

## HOL4 statement

### NO HOL STATEMENT YET

No HOL development of the extension theory exists (see the region-to-satisfaction bridge's section); the guarded former's realization is extension-theory record structure, so a future HOL port of an extension-theory checker would state it.

## HOL verifier receipts

### NONE

no HOL verification receipt exists for this rule.

## Proof

Genre: core rule (tier 1), structural group. The proof is deliberately one step — the rule exists to *relocate* a hypothesis, not to add content — and the substantive work is the semantics adjudication in the second remark, certified by the strictness witness and the wrong-region countermodel bound at this section.

**Claim (sound\_QGuardIntro).** Let  $R$  be the warrant’s region,  $s$  the specification whose warranted safety component is  $\text{SInit}(\varphi)$ , and suppose the region warrant: every state of  $R$  satisfies  $\varphi$ . Then for *any* initial set  $X_0$ , the guarded claim holds: every admitted initial point inside  $R$  meets the body’s demand.

*Proof.* Let  $x \in X_0 \cap R$ . The warrant instantiates at  $x$ :  $x \in R$ , so  $x \models \varphi$ , which is the body’s demand at  $x$ . Since  $x$  was an arbitrary admitted initial point inside the guard region, the pointwise guarded denotation holds. No hypothesis on  $X_0$  was used — the rule is sound for arbitrary initial data, which is exactly what licenses dropping the membership premise.  $\square$

*Remark R38.1* (why pointwise, not blanket). The blanket conditional — *if all of  $X_0$  lies in  $R$ , then the body holds from all of  $X_0$*  — is strictly weaker: on an initial set that merely straddles  $R$ , the blanket antecedent is false and the blanket conditional vacuously true, while the pointwise reading still demands the body from the inside points. The strictness is mechanized (`exists_blanket_not_guardSat`); the pointwise reading is the adopted semantics, and it is the one the introduction rule is sound for.

*Remark R38.2* (wrong region refuted). Substituting any region other than the warrant’s own breaks soundness, by countermodel (`exists_not_guardSat_wrong_region`); the load-time tie (the stored guard region is derived from the warrant row, store-and-check) is what makes the substitution unrepresentable rather than detected.

## Rule 39. QGUARDELIM (core rule)

### The rule (Steele metanotation)

as realized in the mechanized development; source row: QTSL-rules.toml — *QGuardElim*. The metanotation statement is typeset by hand for notational quality; its mechanized ground truth is the Lean statement below, extracted from the sources at every build of this book and hash-bound. The rule *roster* is machine-checked (every mechanized rule tag round-trips to exactly one catalogue row); the statement *text* is editorial, checked by eye against the extracted Lean beside it.

$$\frac{\mathcal{M} \models \text{Guard}(R, s) \quad \text{eval} : \vdash X_0 \subseteq R}{\mathcal{M} \models s}$$

QGUARDELIM is the elimination: a guarded claim plus initial containment yields the body's claim. The membership premise is the same ground computation the unguarded route uses — per region-constructor pair, a degenerate box against a sublevel atom is the exact evaluation leaf, a fat box against a sublevel atom is an enclosure family, and box against box is interval containment — re-entering at exactly one place. Introduction followed by elimination recovers the dissolved region-warranted route whole, so the guarded former adds expressive structure without adding any new soundness surface: everything the pair can conclude, the old route could conclude given the same membership evidence.

What would break without the containment premise is the consumption fence's whole reason: a guarded claim consumed as if unguarded is an unsound *strengthening* — the guarded claim promises nothing off-region, so treating it as the body's claim smuggles in the very hypothesis the former internalized.

**notes** Realized *at consumption*, deliberately — there is no standalone elimination node. Guard-presence triggers the membership demand on any consumer of the claim: the composition rule walks its premise list and demands initial membership for every guarded premise (the quoted consumer-fence axiom below), and the verdict-compile and equivalence evaluators are guard-aware. A consumer that cannot discharge the membership defers loudly rather than assuming it.

### Theory rows (geolog)

The rule's certificate content as it is declared in the geolog theory the checker loads — payload schema, side-condition demands, and axiom rows, quoted from the theory source at every build of this catalogue (a stale quotation cannot exist). Axiom modes: *chase* = the engine derives; *report* = a violation is a loud judgment; *refuse* = a violation gates admission. Side-condition relations are discharged by bounded evaluation at the engine's ground seam, never by derivation.

The baked realization of elimination-at-consumption: list membership over the composition rule's premises, the consumer-fence axiom demanding initial membership for guarded premises, and the ground membership relation it demands.

theory Qtsl . **qsat\_list\_member**

quoted from the theory source at render

```
| qsat_list_member : {list: QSatList, sat: QSat} -> Prop;
```

theory Qtsl . **ax/wf/qwirecompose\_guard\_elim**

quoted from the theory source at render

```

theory Qtsl . **qtsl\_init\_member**

quoted from the theory source at render

```
| qtsl_init_member : {region: QRegionAtom, sys: System} -> Prop;
```

### Lean statement

QtslAux.QGuard . **sound\_QGuardElim**

statement bound

```

/-- Soundness of the elimination rule: the initial-membership evaluation
re-enters exactly here – a guarded claim together with containment of the
initial set in the guard region yields the unguarded claim. -/
theorem sound_QGuardElim {init R : Set X} {sat : X → Prop}
  (hg : GuardSat init R sat) (heval : init ⊆ R) : ∀ x₀ ∈ init, sat x₀

```

QtslAux.QGuard.**qsatFromRegion\_derived**

statement bound

```

/-- Coherence: introduction followed by elimination recovers the
region-warranted record route (warrant plus initial containment yields
satisfaction from every initial point). -/
theorem qsatFromRegion_derived {init R : Set X} {sat : X → Prop}
  (hchild : ∀ x ∈ R, sat x) (heval : init ⊆ R) : ∀ x₀ ∈ init, sat x₀

```

QtslAux.QGuard.**exists\_guardSat\_not\_unguarded**

statement bound

```

/-- The permanent twin of the dropped-membership mutant, stated directly:
elimination WITHOUT its containment premise is false – a guarded claim
does not yield the unguarded one. On `Bool` with the full initial set and
guard region `{true}`, the demand "the state is `true`" is guarded-satisfied
(vacuously off-region, directly on it) yet fails from the initial point
`false`. -/
theorem exists_guardSat_not_unguarded :
  ∃ (init R : Set Bool) (sat : Bool → Prop),
    GuardSat init R sat ∧ ¬ ∀ x₀ ∈ init, sat x₀

```

QtslAux.QGuard.**guardSat\_singleton\_iff**

statement bound

```

/-- At a singleton initial set the guarded denotation is the pointwise
conditional – the shape `Qtsl.Aliases.sound_QSatFromRegion` consumes. -/
theorem guardSat_singleton_iff {R : Set X} {sat : X → Prop} {x₀ : X} :
  GuardSat {x₀} R sat ↔ (x₀ ∈ R → sat x₀)

```

## Correspondence (Steele display ↔ Lean)

**reviewer-certified against the displayed texts** The dictionary below is a reviewer-certified statement of how the mechanized statements above interpret the displayed rule: display metavariable ↔ Lean binder, each display hypothesis ↔ the premise or side condition carrying it, the display conclusion ↔ the goal — with any deliberate difference in width between display and mechanization named outright. Certification is recorded as a hash triple over (the displayed cell, the extracted statement texts, this dictionary's own text); if any of the three changes, this block turns amber until a reviewer re-certifies. The correspondence claim itself remains editorial — reviewer-grade, not machine-checked; its machine-checked successor types each soundness statement against the rule as a structured object, and supersedes this block per rule as it lands.

The display maps onto `sound_QGuardElim` verbatim: the guarded premise ↔ `hg : GuardSat init R sat`; the containment premise  $\vdash X_0 \subseteq R$  ↔ `hsub : init ⊆ R`; the conclusion  $\mathcal{M} \models s \mapsto \forall x \in \text{init}, \text{sat } x$  (the unguarded pointwise demand). The dropped-membership variant is refuted by countermodel (`exists_guardSat_not_unguarded`); the coherence statement `qsatFromRegion_derived` is the factoring of the dissolved region-warranted route through the pair.

## Lean verifier receipts

module QtslAux.QGuard; bound build 3eb84fb9b559... (bound from receipt bd99b3a9109c4daf, 2026-07-28T18:45:47Z). A receipt records that named checking layers accepted a build: (module, compiled-artifact SHA-256, environment SHA-256, checker layers), minted when the checking gate ran; the store receipts attesting the bound build are listed with the layers each run credited. Nothing here asks the reader to trust the store: every layer is an independently runnable program over the quoted sources — rebuild the module and re-run the checkers to reproduce the verdict. Receipts attesting superseded builds credit no layer and are omitted from this rendering (the count of omissions, if any, is noted below).

|------------------|----------------------|--------------------|---------|
| bd99b3a9109c4daf | 2026-07-28T18:45:47Z | build+decorrelated | current |

gate-layer coverage of the bound build:

build (lake build (elaboration)) **current**

replay (leanchecker (official kernel replay)) **none**

hardened (safe\_verify (hardened screen)) **none**

decorrelated (lean4export + nanoda (decorrelated kernel)) **current**

**comparator:** none no fixture in the three-implementation comparator harness (compiled / kernel-interpreted / reference-interpreted) exercises this rule.

## HOL4 statement

### NO HOL STATEMENT YET

As at the introduction rule: no HOL development of the extension theory exists; the consumption fence is extension-theory walk structure.

## HOL verifier receipts

### NONE

no HOL verification receipt exists for this rule.

## Proof

Genre: core rule (tier 1), structural group. One-step proof; the load-bearing content is the consumption fence (a guarded claim consumed as if unguarded is an unsound strengthening), certified by the dropped-membership countermodel.

**Claim (sound\_QGuardElim).** If the guarded claim holds (every admitted initial point inside  $R$  meets the body's demand) and  $X_0 \subseteq R$ , then the body's claim holds from every admitted initial point.

*Proof.* Let  $x \in X_0$ . By containment  $x \in R$ , so  $x \in X_0 \cap R$ , and the guarded claim yields the body's demand at  $x$ .  $\square$

*Remark R39.1* (the fence, and its countermodel). Dropping the containment premise is refuted by countermodel (exists\_guardSat\_not\_unguarded): a guarded claim promises nothing off-region, so an initial point outside  $R$  can violate the body while the guarded claim holds. This is why the elimination is realized *at consumption* — guard-presence triggers the membership demand on any consumer — rather than trusting producers to remember it.

*Remark R39.2* (coherence). Introduction followed by elimination recovers the dissolved region-warranted route whole (qsatFromRegion\_derived): warrant in, guarded claim out, membership in, body's claim out — the same conclusion the old single rule drew from the same two pieces of evidence. The former adds a place to *stand* between them, not a new way to conclude.

## Rule 40. QSafetyBattery (core rule)

### The rule (Steele metanotation)

as realized in the mechanized development; source row: QTSL-rules.toml — *QSafetyBattery*. The metanotation statement is typeset by hand for notational quality; its mechanized ground truth is the Lean statement below, extracted from the sources at every build of this book and hash-bound. The rule *roster* is machine-checked (every mechanized rule tag round-trips to exactly one catalogue row); the statement *text* is editorial, checked by eye against the extracted Lean beside it.

$$\begin{array}{c}
 V : \text{QCertFam} \\
 \{D_m \vdash \mathcal{A}_m V_m \leq 0\}_m \text{ (interiors)} \quad \{\text{slab}_j \vdash g_j \circ V_{m'_j} \leq V_{m_j}\}_j \text{ (guards, per jump } j: \text{ source mode } m_j, \text{ target } m'_j, \text{ reset } g_j) \\
 \{U \cap \bar{D}_m \vdash V_m \geq 1\}_m \text{ (floors)} \quad \{\bar{D}_m \vdash V_m \geq 0\}_m \text{ (nonnegs)} \\
 \text{scope\_warrant} : \text{QInvScope (optional — the dissolved ScopeRule)} \quad p + y \leq 1 \text{ (threshold tie)} \\
 \hline
 \mathcal{M}, x_0 \in \{V \leq y\} \models \text{SProbGE}(p, \text{PAlways } \varphi)
 \end{array}$$

a region written left of the turnstile scopes the row:  $R \vdash P$  asserts  $P$  at every point of  $R$  (each such row is an inherited BL BERNcone-family sequent). The certificate family  $V$  enters as certificate data — a shared reference with no claim content of its own; the rows impose every claim — never as a derivation edge. The threshold tie  $p + y \leq 1$  is the soundness theorem's own hypothesis, displayed as a side condition: unlike the deadline and until nodes (whose baked sorts carry a tie proof field), the baked safety node carries no tie field yet — a named schema divergence, not a checked leaf. The conclusion is the theory row's own judgment, in constructor vocabulary: the region-conditioned probability formula ( $\text{SProbGE}(p, \text{PAlways } \varphi)$ ) on the region  $\text{qraSublevel}(V, y)$ . The record's licensed alias tie is  $\text{SProbGE}(p, \psi) = \text{SReturnGE}(p, \text{retPath } \psi)$  — a return respelling, which does not touch the state-region antecedent; the initial-set hypothesis  $x_0 \in \{V \leq y\}$  left of the judgment is the satisfaction binding's own guard (the theory demands the subject's initial data lie in the concluded region), rendered in the same hypothesis convention as every BERNcone-family sequent. The internalized variant LANDED at the grid re-sort revision: the guarded-spec former (*Guard*, a certificate-stratum record slot carrying the initial-region antecedent) with its introduction rule *QGUARDINTRO* (this catalogue, the structural group). The hypothesis form remains this catalogue's rendering convention (one convention catalogue-wide); the guarded former is its internalized spelling, one *QGUARDINTRO* application away, and no belief-gauge reading is displayed.

QSafetyBattery is the probabilistic safety battery: from a family of purely polynomial premise rows about a certificate  $V$ , it concludes that with probability at least  $p$  the system satisfies  $\text{PAlways } \varphi$  (surface syntax  $G \varphi$ ) — *forever* — from every start state in the sublevel region  $\{V \leq y\}$ . The rule concludes a satisfaction judgment ( $\models$ ), one theory-extension edge above the base calculus, and every premise row is an inherited base-calculus sequent: *interior* rows say the certificate does not increase along the in-mode dynamics, *guard* rows say jumps do not increase it, *floor* rows say  $V \geq 1$  on the avoid set (the compiled over-approximation of where  $\varphi$  fails), and *nonneg* rows say  $V \geq 0$  on the domain hull. The battery adds zero kernel arithmetic; its entire content is the supermartingale assembly one level up:  $V$  read along the process and stopped at the first failure is a nonnegative supermartingale, and Ville's inequality converts its initial value into a bound on the probability of ever failing.

A producer reaches for the rule wherever a quantitative safety guarantee over a hybrid stochastic system is wanted. The certificate is found by whatever synthesis method the producer likes (typically linear or sum-of-squares programming over the same polynomial cones the premise rows are checked in); only the rows ship in the certificate.

What the checker recomputes are the side conditions: the domain-hull condition (one step from any in-scope state stays inside the hull  $\bar{D}$ , which is exactly where the floor and nonneg rows were checked), the fail-closed containment (one-step mass stays in  $D \cup U$ ; leaving the modelled domain is counted as *failure*, never as silent success), and the floor-scope resolution (the floor rows' scopes resolve to an exact cover of the avoid set within the hull). The threshold tie  $p + y \leq 1$  is displayed as a side condition, not a checked leaf: it is the soundness theorem's own hypothesis, and the baked safety node carries no tie proof field yet (contrast the deadline and until nodes) — a named schema divergence, as the rule's flavor text states.

Each hypothesis is load-bearing. Drop the floors and failure is free of charge: a certificate identically 0 satisfies every other row and would certify almost-sure safety of a chain that fails at its first step. Drop the nonnegs and the maximal inequality itself fails — a signed process can pay for a barrier visit with mass borrowed from below. Drop the fail-closed containment and probability mass could exit the modelled domain unaccounted. Drop the threshold tie and the conclusion would assert success probability  $p$  alongside a failure budget  $y$  with  $p + y > 1$ . The proof section walks each of these, with counterexamples.

The dashboard row's mark states the status honestly: the hash-bound theorems warrant the rule at the *discrete-kernel profile* — system semantics a one-step Markov kernel on the flattened hybrid state space, interior rows read as one-step expected decrease (the Foster–Lyapunov reading) — with the PDMP sub-profile of the continuous-time semantics additionally machine-checked end-to-end. The general continuous-time profile (jump–diffusion) is *proven*, at the martingale-problem presentation: the system enters through its generator drift data,  $\mathcal{A}V$  as data with the martingale-problem hypothesis for the pair, and the battery's conclusion follows end-to-end (sound\_GSHS\_safety\_mp, sound\_GSHS\_safety\_battery\_mp, module QtslAux.LayerD.MPDDischarge of the semantic-universe strand's auxiliary package) — the same epistemic shape as the staged-row theorem's (sound\_QSafetyBattery\_staged) mixture bridge: an explicit presentation hypothesis, quantifying over exactly the systems whose presentation satisfies it. The martingale-problem theorems are hash-bound below like every other block — their package, the semantic-universe strand's auxiliary package in the public tree, is registered with this catalogue's binder — so the dashboard row carries no conditional mark: each named profile is proven, and its theorems are bound.

At the general stratum the battery's shape is also stated over the semantic universe itself, in the semantic-universe functor package (hash-bound below): trajectories live as closed record sets under the Fell topology, and the undisplayed regularity pack — the measurability the profile proofs *assume* of their region events — restates there as a theorem of the site's topology: the confinement event of a closed safe region is Borel over every trajectory window, with no compactness and no  $\sigma$ -compactness anywhere (measurableSet\_confinedEvent\_cylinder). On that carrier the safety conclusion is a *wall* — a  $\forall$ -face spec: per-window confinement classes are closed under record restriction, their persistence follows from window-calculus transitivity alone, and the judgment bridge is an equivalence — satisfaction *equals* almost-sure confinement at the window (satAtM\_safetySpecF\_iff), with the indicator calculus admitted exactly by the measurability above (pull\_indPenM). Two further site-level facts sharpen the story. Record confinement of a trajectory's closed-up graph to a closed wall is *pointwise* safety at every stage, unconditional in the trajectory (graphCl\_mem\_confinedEvent\_iff) — the segment-constancy side condition a skeleton-based route would carry is absent by construction. And composing two wall demands along a window compositor yields exactly the wall demand of the glued record class (mboxplusWF\_indPenM): wall specs are closed under composition, and persistence survives it. These statements bind the site-general stratum — the acceptance events and spec classes that every profile's conclusion instantiates; the displayed judgment's warrant remains with the profile theorems above.

**notes** Fail-closed as a design reading: the underlying theorem's concluded event is *stronger* than the safety formula's truth set — never fail *and* never leave the modelled domain — and the formula tie then weakens it. The node presents its premises per mode and per jump (mode-indexed certificate families); the bound theorem for that shape assembles the flattened generator row through a sub-convex mixture decomposition of the one-step kernel — the mode's flow step plus the enabled guard jumps — which is the presentation-to-semantics bridge, carried as an explicit hypothesis and quoted in the proof's final remark.

## Theory rows (geolog)

The rule's certificate content as it is declared in the geolog theory the checker loads — payload schema, side-condition demands, and axiom rows, quoted from the theory source at every build of this catalogue (a stale quotation cannot exist). Axiom modes: chase = the engine derives; report = a violation is a loud judgment; refuse = a violation gates admission. Side-condition relations are discharged by bounded evaluation at the engine's ground seam, never by derivation.

In the geolog theory the checker loads, every object this rule touches is a declared row, and the display's remaining ambient notation resolves as follows. The concluded formula  $\text{SProbGE}(p, \text{PALways } \varphi)$  (surface syntax  $P_{\geq p}[G\varphi]$ ) is the safety-face cap former  $\text{SProbGE}$  (concluding into the record's  $\forall$ -component sort) applied at the path former  $\text{PALways}$  — the probability-floor former whose threshold canonicity is the range axiom quoted below. The displayed  $\mathcal{M}$  is the paired subject: a `System` element, bound to the claim by the `QSat` pairing (the specification consumes this formula among its safety components; the warrant row names it). The generator reads  $\mathcal{A}_m V_m$  are not free-floating operator applications: `qtsl_gen_form` is the derived generator-form seam — given the subject system and a certificate component (a hypernet from the state space to the nonnegative extended reals), the row names the hypernet saying how the certificate can change with duration, recomputed from the subject's content rows and never trusted as stored data. The battery's E2 payload is the `QSafetyBattery` entity below, field for field the display's premise kit; the conclusion region `qraSublevel(V, y)` is the region-atom constructor of the same name.

```

BernsteinLogicAux.Battery.sound\_QSafetyBattery\_failClosed

statement bound

```

/-- **`sound_QSafetyBattery`, discrete profile, fail-closed form** (the discrete-kernel
profile: the hybrid model flattened to one measurable state space with a single one-step
Markov kernel `K`). Hypotheses
are the checked rows (B1)^(B2) as the kernel drift row, (B3) floors, (B4) nonnegs, the
side conditions (R3) (hull: `D ⊆ D̄` and one-step mass in `D̄`) and (R4) (fail-closed:
one-step mass in `D ∪ U`), the threshold arithmetic (θ) `p + thr ≤ 1` (the staged
`q_add`/`q_le` vocabulary, in exact  $\mathbb{Q}$ ), and a start state in the concluded region
`D n {V ≤ thr}` (`qraSublevel`). Conclusion: with probability at least `p` the chain
remains in `D \ U` **forever** – never reaching the avoid region and never leaving the
modeled domain. This is the strong (fail-closed) reading of the concluded `QRegionSat`;
`sound_QSafetyBattery` weakens it through the formula tie (F).

```

The `Integrable V (K y)` hypothesis is the discrete reading of  
"domain membership of `V` in the extended generator's domain"; for the intended  
instances (`V` polynomial, one-step images in the compact  
`D̄` by (R3)) it is automatic. -/

```

**Discharging the supermartingale property, generic half.** The first analytic field's martingale theory is also a library application: the exponential-discounting theorem produces the required supermartingale from a martingale-problem hypothesis (the compensated certificate process is a martingale — what Itô's formula and the interior rows establish per model, with no stochastic integration in the certified statement), the bounded-horizon and horizon-free optional-sampling inequalities are the theorems the interface discharge above consumes, and the continuous-time Doob/Ville maximal inequality converts supermartingale level crossings into probability bounds. What remains per model is exactly the martingale-problem hypothesis and the uniform bounds it consumes.

BernsteinLogicAux.OptionalStoppingRC.supermartingale\_exp\_discount

statement bound

```

/-- **Exponential discounting of a drift-dominated process.** Suppose
`W :  $\mathbb{R}_{\geq 0} \rightarrow \Omega \rightarrow \mathbb{R}$ ` is adapted with continuous paths, `g :  $\mathbb{R}_{\geq 0} \rightarrow \Omega \rightarrow \mathbb{R}$ ` is
jointly measurable, both are uniformly bounded, the compensated process
`fun t  $\omega \Rightarrow W\ t\ \omega - \int s \text{ in } (0 : \mathbb{R})..(t : \mathbb{R}), g\ s.\text{toNNReal } \omega` is a
martingale (the martingale-problem formulation of `g` being the generator
drift of `W`), and `g t  $\omega \leq c * W\ t\ \omega` pointwise. Then

`fun t  $\omega \Rightarrow \text{Real.exp } (-c * t) * W\ t\ \omega` is a supermartingale.

This is the discounting step of Dynkin-formula arguments, carried out with
pathwise Riemann–Stieltjes integration by parts against the `C` function
`s  $\mapsto \text{exp } (-c * s)$ ` and a conditional Fubini argument – no stochastic
integral is involved. -/

The staged-row form binds the rule's premise shapes as the schema realizes them: per-mode interior rows against the mode's flow mechanism, per-jump guard rows, per-mode floors and nonnegs, and the exact- $\mathbb{Q}$  threshold row cast once — assembled onto the flattened battery through the mixture bridge discussed in the proof section's final remark.

BernsteinLogicAux.QtslBattery . sound\_QSafetyBattery\_staged

statement bound

```
/-- **sound_QSafetyBattery_staged** – the `QSafetyBattery` node's staged
right column (QTSL-rules.toml row `QSafetyBattery`,
amended side) as a bound theorem, discrete-kernel profile. Hypothesis
families mirror the staged rosters:

* `hB1` **interiors** – per mode `m`, the flow chart's one-step drift
   $\int V_m d(\text{flow}_m z) \leq V_m z$  on  $D_m \setminus U_m$  (the refined admissible scope;
  the B1 row), with `hint` its domain-membership integrability;
* `hB2` **guards** – per jump `j`, the boundary row
   $V_{\{dst\ j\}}(g_j z) \leq V_{\{src\ j\}} z$  on the guard slab (the B2 row);
* `hB3` **floors** and `hB4` **nonnegs** – per mode on  $U \cap D_m / D_m$ 
  (the B3/B4 rows);
* `h0` – the threshold row  $p + thr \leq 1$  in **exact  $\mathbb{Q}$ **, the staged
  `q_add`/`q_le` vocabulary, cast once here;
* `hR3`/`hR4` – the registry side conditions at the compiled kernel;
* `hmix` – **the System bridge**: the presentation's
  charts compile, at this profile, to the step kernel `K` – pointwise, the
  one-step measure from any in-scope state is a sub-convex mixture of the
  mode's flow step and the jumps enabled there (weights supported on
   $\{src\ j = m \wedge z \in G\ j\}$ ). A System whose compilation satisfies `hmix` is
  exactly what stands left of the concluded  $\models$ .
```

Conclusion: region-level, as the concluded `QRegionSat` with the  
`qraSublevel(V, thr)` atom reads – from every start in  
 $D_m \cap \{V_m \leq thr\}$ , the chain satisfies  $G \emptyset$  with probability at least  
`p`. Assembled onto `sound\_QSafetyBattery` through `mixture\_drift` /  
`mixture\_integrable`; the GSHS-profile transport is the standing  
residue. -/

```

**The general stratum: acceptance events on the record carrier.** Over the semantic universe's Fell carrier the safety acceptance event is measurable by the topology of the site rather than by assumption: confinement events of closed walls are Fell-closed, hence

Borel under the Effros structure — over every trajectory window, with no compactness hypothesis anywhere.

SuFunctor.Site.FellAcceptance . **measurableSet\_confinedEvent**

statement bound

```
/-- The safety acceptance event of a closed wall is Borel – no
compactness, no  $\sigma$ -compactness, no Hausdorffness. -/
theorem measurableSet_confinedEvent {A : Set  $\alpha$ } (hA : IsClosed A) :
  MeasurableSet (confinedEvent A)
```

SuFunctor.Site.FellAcceptance . **measurableSet\_confinedEvent\_cylinder**

statement bound

```
/-- **The safety acceptance event is Borel over every window**: the
confinement event of a closed safe region's cylinder, with no
compactness and no  $\sigma$ -compactness – the A8 discharge of the safety
battery's measurability pack. -/
theorem measurableSet_confinedEvent_cylinder {D : Set X}
  (hD : IsClosed D) :
  MeasurableSet
    (confinedEvent ((Set.univ : Set  $\iota$ W)  $\times^s$  D) : Set (FTraj W X))
```

**Walls over the record carrier.** The battery's conclusion shape at the general stratum: per-window confinement classes with the full judgment bridge (satisfaction equals almost-sure confinement), the indicator transport law that admits them, the closed-graph strengthening (record confinement is pointwise safety, unconditional in the trajectory), and the composition seam (the window compositor of two wall demands is the wall demand of the glued class — persistence survives composition).

SuFunctor.Site.FellBehaviorSpec . **indPenM**

statement bound

```
/-- The indicator penalty of a class at the general stratum: permitted
outright iff the joint's mass avoids the class's complement, forbidden
outright otherwise. Total in the class (mathlib's outer-measure
evaluation); its transport law below is where measurability binds. -/
def indPenM (S : Set K) : MeasPen K
```

SuFunctor.Site.FellBehaviorSpec . **pull\_indPenM**

statement bound

```
/-- **Transport of the indicator along a measurable map is the
indicator of the preimage** – the general-stratum form of
`pull_indPen`, with the two measurability hypotheses that stratum
charges: the map's, and the class's. The latter is the A8 admission
ticket: only Borel acceptance events enter the indicator calculus. -/
theorem pull_indPenM (h : K  $\rightarrow$  L) (hm : Measurable h) {S : Set L}
  (hS : MeasurableSet S) :
  MeasPen.pull h (indPenM S) = indPenM (h  $^{-1}$ ' S)
```

SuFunctor.Site.FellBehaviorSpec . **isPersistentMF\_clipDemandsF**

statement bound

```
/-- **Persistence of clip demands**: window-calculus transitivity
alone (`penExtMF_penExtMF`), with openness of the site's windows as
the only hypothesis. No condition on the bases whatsoever. -/
theorem isPersistentMF_clipDemandsF (U :  $\iota \rightarrow$  Set T)
  (hU :  $\forall i$ , IsOpen (U i))
  (base :  $\forall i$ , MeasPen (FTraj (U i) X)) :
  IsPersistentMF U (clipDemandsF U base)
```

SuFunctor.Site.FellBehaviorSpec . **satAtM\_specOfBehaviorF\_iff**

statement bound

```
/-- **The judgment bridge at the general stratum**: a joint satisfies
the spec of a Fell behavior subtype at a window iff its mass lies in
the class there. Forward consumes the reflexive demand; backward
consumes the subpresheaf condition, clip measurability (openness of
the site's windows), and class measurability (the A8 ticket) – each
exactly once. -/
theorem satAtM_specOfBehaviorF_iff (U :  $\iota \rightarrow$  Set T)
  (hU :  $\forall i$ , IsOpen (U i)) (B : WBehaviorF U X)
  (hB :  $\forall i$ , MeasurableSet (B.cls i)) (j :  $\iota$ )
  ( $\mu$  : MeasJoint (FTraj (U j) X)) :
  SatAtM  $\mu$  (specOfBehaviorF U B j)  $\leftrightarrow$ 
  ( $\mu.1$  : Measure (FTraj (U j) X)) (B.cls j) $^c$  =  $\emptyset$ 
```

SuFunctor.Site.FellBehaviorSpec . satAtM\_safetySpecF\_iff

statement bound

```

/-- The safety wall's judgment bridge, with its measurability paid by
A8: for a closed safe region, satisfaction of the safety spec at a
window is almost-sure confinement there – the SU-general form of the
safety battery's acceptance reading, with the measurability pack
discharged by the topology of the site. -/
theorem satAtM_safetySpecF_iff (U :  $\mathbb{1}$  → Set T)
  (hU :  $\forall i$ , IsOpen (U i)) {D : Set X} (hD : IsClosed D) (j :  $\mathbb{1}$ )
  ( $\mu$  : MeasJoint (FTraj (U j) X)) :
  SatAtM  $\mu$  (specOfBehaviorF U (safetyBehaviorF U D) j)  $\leftrightarrow$ 
  ( $\mu.1$  : Measure (FTraj (U j) X))
  (confinedEvent ((Set.univ : Set  $\mathbb{1}$ (U j))  $\times^s$  D))c = 0

```

SuFunctor.Site.FellBehaviorSpec . graphCl\_mem\_confinedEvent\_iff

statement bound

```

/-- **The A5 strengthening**: record confinement of a trajectory's
closed-up graph to a closed wall is pointwise confinement at every
stage – unconditional in the trajectory. The skeleton route's
segment-constancy side condition is absent by construction: the record
constrains every `(t, x)` of the closed graph, mid-segment stages
included, and the closure completion costs nothing against a closed
wall. -/
theorem graphCl_mem_confinedEvent_iff {D : Set X} (hD : IsClosed D)
  (f : Traj W X) :
  graphCl f  $\in$  confinedEvent ((Set.univ : Set  $\mathbb{1}$ W)  $\times^s$  D)  $\leftrightarrow$ 
   $\forall w, f w \in D$ 

```

SuFunctor.Site.FellBehaviorSpec . mboxplusWF\_indPenM

statement bound

```

/-- **The record-carrier composition seam on indicators** (the
general-stratum sibling of `boxplusW_indPen`): the window compositor
of two wall demands is the wall demand of the glued record class –
the pullback intersection along the two state transports. Properness
feeds the transports' measurability, and the classes' measurability
is the A8 ticket again. This is the A4 transport core: composing
wall specs along the compositor never leaves the wall fragment, so
the composed conclusion is again a per-window class demand, and
persistence survives by `IsPersistentMF.image2_mboxplusWF`. The
per-profile grid cells of the wire-composition rule (ODE, sampled
data, gauge-form feedback) are drift-assembly content at the
presentation profiles, deliberately not restated here. -/
theorem mboxplusWF_indPenM {W : Set T} { $\pi_1$  : Z → U} { $\pi_2$  : Z → V}
  (hp1 : IsProperMap  $\pi_1$ ) (hp2 : IsProperMap  $\pi_2$ )
  {S1 : Set (FTraj W U)} {S2 : Set (FTraj W V)}
  (hS1 : MeasurableSet S1) (hS2 : MeasurableSet S2) :
  mboxplusWF  $\pi_1$   $\pi_2$  (indPenM S1) (indPenM S2)
  = indPenM (fellMap (W

```

## Correspondence (Steele display $\leftrightarrow$ Lean)

**a bound Lean statement CHANGED since certification — re-review and re-certify** The dictionary below is a reviewer-certified statement of how the mechanized statements above interpret the displayed rule: display metavariable  $\mapsto$  Lean binder, each display hypothesis  $\mapsto$  the premise or side condition carrying it, the display conclusion  $\mapsto$  the goal — with any deliberate difference in width between display and mechanization named outright. Certification is recorded as a hash triple over (the displayed cell, the extracted statement texts, this dictionary's own text); if any of the three changes, this block turns amber until a reviewer re-certifies. The correspondence claim itself remains editorial — reviewer-grade, not machine-checked; its machine-checked successor types each soundness statement against the rule as a structured object, and supersedes this block per rule as it lands.

Model frame as at QBASIN, probabilistically read: the displayed  $\mathcal{M}$ ,  $x_0 \in \{V \leq y\} \models \text{SProbGE}(p, \text{PAlways } \varphi) \mapsto$  the goal ofReal  $p \leq \text{pathMeasure } K \times \{\omega \mid \forall n, \text{sat } (\omega n)\}$  for every start in the concluded region — sat the  $\varphi$ -satisfaction predicate, of which *no measurability is asked* (the fail-closed event is the measurable one; the tie weakens by `measure_mono`). The staged-row theorem `sound_QSafetyBattery_staged` is the amended display's binding; the flattened `sound_QSafetyBattery` is its engine.

- profile, stated plainly: the map splits in two. The bullets below marked *discrete map* bind the rule at the *discrete-kernel profile* —  $\mathcal{M}$ 's step semantics is a Markov kernel chain, its trajectory measure rendered as `pathMeasure` in the bound statements

— via `sound_QSafetyBattery_staged`, with the PDMP sub-profile carried end-to-end by `sound_GSHS_safety_battery`. The martingale-problem theorems (`sound_GSHS_safety_mp`, `sound_GSHS_safety_battery_mp` — hash-bound below) are the *continuous-time avoidance engine*, mapped separately in the *MP map* bullet; they do not themselves bind the full displayed judgment.

- *MP map*, its own binders and its own goal: the generator presentation and the interior rows  $\mapsto \text{hmp} : \forall x, \text{Nonempty } (\text{MPFlow } M \ 0 \ V \ x)$  (the martingale-problem presentation hypothesis, carried as data); guards  $\mapsto \text{hForce} : \text{ForcedNonexpansion } M \ V$ ; nonnegs  $\mapsto \text{hNonneg} : \text{NonnegV } V$ ; floors  $\mapsto \text{hFloor} : \forall y \in U, 1 \leq V \ y$ ; the threshold row  $\mapsto \text{h}\theta$ , and the start  $\mapsto x/\text{hthr}$ . Undisplayed MP regularity, named outright:  $\text{hV}/\text{hU}$  (measurability),  $\text{hC}\theta/\text{hVC}$  (a global certificate bound  $C'$ ), and the `IsMarkovKernel` instances on `M.seg/M.jump`. Honesty about the goal: the MP battery's literal conclusion is skeleton avoidance — of  $\text{Real } p \leq \text{Battery.pathMeasure } (\text{skel } M) (\text{SkelState.alive } x) \{ \omega \mid \forall n, \omega \ n \notin \text{skelBad } U \}$  — avoidance of the  $U$ -bad set along the embedded skeleton, not the displayed  $\text{SProbGE}(p, \text{PAways } \varphi)$  judgment verbatim; the formula tie from  $\varphi$  to  $U$  is the discrete map's  $\text{hF}$  business, and only the discrete staged theorem binds the displayed judgment itself.
- *discrete map* — what stands left of the  $\models \mapsto \text{hmix}$ , the System bridge: the presentation's charts compile to the kernel as a sub-convex mixture of the mode's flow step and the enabled jumps — an explicit hypothesis, so the certified statement quantifies over exactly the Systems whose compilation satisfies it.
- *discrete map* — the four premise families map one-to-one: interiors  $\mapsto \text{hB1}$  (per-mode one-step flow drift on  $D_m \setminus U_m$ ) with the undisplayed integrability rider `hint`; guards  $\mapsto \text{hB2}$  (per-jump boundary rows on the guard slab); floors  $\mapsto \text{hB3}$  (on  $U \cap \bar{D}_m$ , the ruled fail-closed scope); nonnegs  $\mapsto \text{hB4}$ .
- *discrete map* — the threshold tie  $p + y \leq 1$  (a side condition in the display)  $\mapsto \text{h}\theta$ , in exact  $\mathbb{Q}$ , cast once inside the statement.
- *discrete map* — side conditions  $\text{R3}/\text{R4} \mapsto \text{hR3}/\text{hR4}$  at the compiled kernel (hull containment; fail-closed reset containment); the formula tie  $U := \text{cmpl}(\varphi) \mapsto \text{hF} : \neg \text{sat } y \rightarrow y \in U$  — note the certified hypothesis asks only that  $U$  *over-approximate* the falsity set: strictly wider than the displayed equation, in the safe direction.
- *discrete map* — conclusion region  $\text{qraSublevel}(V, y) \mapsto$  the start conditions  $z \in D_m \ m$  and  $V \ m \ z \leq \text{thr}$  (the Lean source's own identifier for the display's  $y$ ), region-level as the judgment reads.

Width note: measurability of the region/certificate data ( $\text{hDm}/\text{hDbarm}/\text{hUm}/\text{hVmeas}$ ) and the interior integrability rider are profile-level regularity with no displayed rows — the probabilistic sibling of the `PsdCERT` evaluability pack; every mandatory displayed row is consumed — the display's *optional* `scope_warrant` slot (the dissolved `ScopeRule`'s interface) is taken by neither certified statement and has no entry in this map — and the two widenings (over-approximating  $U$ , sub-convex  $\text{hmix}$ ) both enlarge the certified reach beyond the display's letter.

## Lean verifier receipts

module `BernsteinLogicAux.Battery`; bound build `2fd1c031c80b...` (bound from receipt `8d9ccb68993ea0ec`, 2026-08-04T01:56:55Z). A receipt records that named checking layers accepted a build: (module, compiled-artifact SHA-256, environment SHA-256, checker layers), minted when the checking gate ran; the store receipts attesting the bound build are listed with the layers each run credited. Nothing here asks the reader to trust the store: every layer is an independently runnable program over the quoted sources — rebuild the module and re-run the checkers to reproduce the verdict. Receipts attesting superseded builds credit no layer and are omitted from this rendering (the count of omissions, if any, is noted below).

| receipt          | minted               | layers             | status  |

comparator: none no fixture in the three-implementation comparator harness (compiled / kernel-interpreted / reference-interpreted) exercises this rule.

## HOL4 statement

### NO HOL STATEMENT YET

The HOL4 development ports the base calculus's checker chain (theory `bern_catalogue`, developed side by side with the base catalogue sources, stopping below the proof-object layer); it contains no probability or measure theory. `QSAFETYBATTERY` lives one theory-extension edge above the base calculus — it concludes a satisfaction judgment, not a sequent — and its soundness content is path-space measure theory (trajectory kernels, stopped supermartingales, Ville's inequality), for which no counterpart exists anywhere in the ported development. A HOL statement of this rule would be a new measure-theoretic campaign, not an extension of the ported checker chain; until one exists, this box records the current state of the edifice.

## HOL verifier receipts

### NONE

no HOL verification receipt exists for this rule.

## Proof

Genre: core rule (tier 1) — an ordinary mathematical proof at Putnam-exam-solution detail. This rule concludes a *satisfaction judgment* ( $\models$ ), one theory-extension edge above the base calculus: every premise row is an inherited base-calculus sequent, and soundness is proved *given* base soundness (the extension-edge convention). The theorems quoted above warrant the rule at the **discrete-kernel profile**; the profile remark at the end of this section states exactly what remains a hypothesis beyond it. Lemmas [R40.1–R40.3](#) and Proposition [R40.4](#) are the battery family's shared probabilistic preamble.

**Setting and claim.** Fix a measurable state space  $S$  — the flattened hybrid state space, i.e. the disjoint sum of the per-mode domains — and a Markov one-step kernel  $K$  on  $S$ , carrying both discretized flow steps and guarded jumps. For  $x \in S$  write  $\Pr_x$  for the path measure on  $S^{\mathbb{N}}$ : the trajectory law of the time-homogeneous chain driven by  $K$ , started deterministically at  $x$  (the Ionescu–Tulcea construction, with the constant kernel family).  $(\mathcal{F}_n)_n$  is the canonical filtration,  $\mathcal{F}_n$  generated by the coordinates  $\leq n$ .

The rule's data: a modelled domain  $D$ , a hull  $\bar{D} \supseteq D$  (the region on which the polynomial rows were actually checked), an avoid set  $U$  compiled to over-approximate the falsity set of the G-argument —  $D, \bar{D}, U$  all measurable subsets of  $S$ , as is every region a row speaks on, here and in the sibling rules riding this substrate — a measurable certificate  $V : S \rightarrow \mathbb{R}$ , and rationals  $p, y$ . The checked rows and side conditions, read semantically at this profile:

(B1 $\wedge$ B2) *generator*: for every  $z \in D \setminus U$ ,  $V$  is integrable against  $K z$  and  $\int V dK z \leq V(z)$ . (At this profile the interior and guard rows land *together*: the one-step kernel carries flow and enabled jumps in a single step, so the two row families compile to one kernel-level generator row.)

(B3) *floors*:  $V \geq 1$  on  $U \cap \bar{D}$ .

(B4) *nonnegs*:  $V \geq 0$  on  $\bar{D}$ .

(R3) *hull*: for every  $z \in D \setminus U$ ,  $K z(\bar{D}) = 1$  — one-step mass stays where the rows were checked.

(R4) *fail-closed containment*: for every  $z \in D \setminus U$ ,  $K z(D \cup U) = 1$ .

( $\Theta$ ) *threshold*:  $p + y \leq 1$ , checked in exact rational arithmetic.

(F) *formula tie*:  $\neg \text{sat}(z) \Rightarrow z \in U$ , where  $\text{sat}$  is the state-satisfaction predicate of the G-argument  $\varphi$ .

The claim (`sound_QSafetyBattery`): for every  $x \in D$  with  $V(x) \leq y$ ,

$$\Pr_x^*[\forall n, \text{sat}(\omega_n)] \geq p$$

— outer measure, because no measurability is ever asked of the satisfaction predicate (Lemma R40.3 states the convention); it coincides with the ordinary probability whenever the satisfaction event is measurable.

**Lemma R40.1** (the stopped certificate). *Let  $f : S \rightarrow \mathbb{R}$  and let  $A \subseteq S$  be a stop set. Define the stopped certificate process  $X_n(\omega) := f(\omega_{n \wedge \tau_A})$ , where  $\tau_A$  is the first visit to  $A$  — equivalently, by the primitive recursion that freezes the value once  $A$  has been visited. Then: (i) if  $A$  is measurable and  $f$  is measurable,  $X$  is adapted to  $(\mathcal{F}_n)$ ; (ii) any pointwise property of  $f$ 's values holds of  $X$ 's values; (iii) barrier transport: if  $f \geq 1$  on  $A$ , then  $X_n \geq 1$  on the event  $\{\tau_A \leq n\}$ ; (iv)  $X_n$  depends only on the coordinates  $\leq n$ .*

*Proof.* All four are elementary inductions on  $n$  over the two branches of the recursion (surviving:  $X_{n+1} = f(\omega_{n+1})$ ; frozen:  $X_{n+1} = X_n$ ). No stopping-time API is needed anywhere — the recursion is the stopped process, and (iii) is proved by chasing the first index at which  $A$  was visited.  $\square$

**Lemma R40.2** (supermartingale bridge). *Let  $f$  be measurable with  $0 \leq f \leq C$ , let  $A$  be measurable, and suppose the one-step generator row holds off  $A$ : for all  $z \notin A$ ,  $\int f dK z \leq f(z)$ . Then for every start  $x$ , the stopped certificate  $X$  of Lemma R40.1 is a supermartingale with respect to  $(\mathcal{F}_n, \Pr_x)$ .*

*Proof.* Integrability is the bound  $0 \leq X_n \leq C$  (Lemma R40.1(ii)). For the supermartingale inequality, condition on  $\mathcal{F}_n$ : by the Markov property of the trajectory construction, the conditional expectation of a bounded  $\mathcal{F}_{n+1}$ -measurable function given  $\mathcal{F}_n$  is its integral against the trajectory kernel continued from the  $n$ -prefix. Split on the survival event  $S_n := \{\omega : \omega_k \notin A \text{ for all } k \leq n\}$  —  $\mathcal{F}_n$ -measurable,  $A$  being measurable, and determined by the coordinates  $\leq n$ , so paths patched to agree with  $\omega$  up to  $n$  have the same survival status. On the surviving branch the integrand is  $f$ (next coordinate), whose one-step marginal is  $K(\omega_n)$ ; since survival means  $\omega_n \notin A$ , the generator row applies and the conditional expectation is  $\leq f(\omega_n) = X_n(\omega)$ . On the frozen branch the integrand is the constant  $X_n(\omega)$ . Note that every hypothesis here is pointwise — there is no almost-everywhere invariance argument anywhere in the bridge; this is what the fail-closed design buys, and the reachability sibling (`QDeadlineBattery`) will have to pay precisely this cost when it can no longer enlarge its stop set.  $\square$

**Lemma R40.3** (Ville's inequality, barrier form). *Let  $X$  be a nonnegative supermartingale with  $X_n \geq 1$  on the event  $\{\text{some coordinate } \leq n \text{ lies in } A\}$ . Then  $\Pr_x^*[\exists n, \omega_n \in A] \leq \mathbb{E} X_0$ , where  $\Pr_x^*$  is the outer measure — equal to the ordinary probability whenever the visit event is measurable, as it is at every consumption in this family ( $A$  is measurable there).*

*Proof.* This is the maximal inequality for nonnegative supermartingales at barrier 1 [234] (textbook treatment: [64]): the probability that a nonnegative supermartingale ever reaches level  $a$  is at most  $\mathbb{E} X_0/a$ . The mechanized form deliberately asks no measurability of the visit event itself — the bad event is bounded by inclusion in the measurable event  $\{\exists n, X_n \geq 1\}$ , whose probability the maximal inequality bounds, and only the process needs to be adapted; the outer-measure phrasing of the conclusion is exactly this inclusion, spelled.  $\square$

**Proposition R40.4** (the battery pattern). *Let  $A$  be measurable and let  $f$  be measurable with  $0 \leq f \leq C$  globally,  $f \geq 1$  on  $A$ , and one-step drift off  $A$ . Then for every  $x$ ,*

$$\Pr_x[\exists n, \omega_n \in A] \leq f(x).$$

*Proof.* Lemmas R40.1–R40.3 assembled; the initial value is  $\mathbb{E} X_0 = f(x)$  because coordinate 0 is deterministically  $x$ . This proposition — nonnegative supermartingale + barrier + initial value  $\Rightarrow$  probability bound — is the shape every rule in the battery family consumes; the siblings cite it as “the battery pattern (`QSafetyBattery`, Proposition R40.4)”.  $\square$

**Lemma R40.5** (the clamp: from checked rows to global hypotheses). *The rows (B3), (B4) speak only on  $\bar{D}$ , while Proposition R40.4 wants its bounds globally. Set  $A := U \cup D^c$  (the fail-closed stop set),  $C := \max(y, 1)$ , and let  $g$  be the clamped certificate: on  $D$ , clamp  $V$  into  $[0, C]$ ; off  $D$ , clamp  $\max(V, 1)$  into  $[0, C]$  (so the floor is forced off the modelled domain). Then: (i)  $0 \leq g \leq C$  globally; (ii)  $g \geq 1$  on  $A$ ; (iii) on  $\bar{D} \cap (D \cup U)$  the clamp is invisible:  $g = \min(V, C)$  there; (iv) under (R3) + (R4),  $g$  satisfies the one-step generator row off  $A$ ; (v)  $g(x) = V(x)$  at any  $x \in D$  with  $V(x) \leq y$ . Throughout,  $g$  is measurable: a case split between measurable pieces ( $V$ ,  $D$  measurable) composed with clamps — so  $(g, A)$  is an admissible input to Proposition R40.4.*

*Proof.* (i), (ii), (v) are case checks from (B3), (B4) and the definition — (ii) uses (B3) on  $U \cap \bar{D}$  and the forced floor off  $D$ . (iii): on  $D$  the lower clamp is inert by (B4); on  $(\bar{D} \cap U) \setminus D$  the forced floor is inert by (B3). For (iv), fix  $z \in D \setminus U$  (i.e.  $z \notin A$ ). By (R3) and (R4) the one-step measure  $K z$  is carried by  $\bar{D} \cap (D \cup U)$  — the complement has measure  $\leq K z(\bar{D}^c) + K z((D \cup U)^c) = 0$  — so by (iii) the integrand may be replaced by  $\min(V, C)$ . Then  $\int \min(V, C) dK z \leq \min(\int V dK z, C) \leq \min(V(z), C) = g(z)$ , using monotonicity of the integral, the generator row (B1 $\wedge$ B2), and (iii) at  $z$  itself.  $\square$

**Theorem R40.6** (fail-closed form). *Under (B1)–(B4), (R3), (R4), ( $\Theta$ ): for every  $x \in D$  with  $V(x) \leq y$ ,*

$$\Pr_x[\forall n, \omega_n \in D \setminus U] \geq p.$$

*Proof.* Apply Proposition R40.4 to  $(g, A)$  of Lemma R40.5:  $\Pr_x[\text{reach } A] \leq g(x) = V(x) \leq y$ . The complement of ever visiting  $A = U \cup D^c$  is exactly  $\{\forall n, \omega_n \in D \setminus U\}$ , so its probability is at least  $1 - y \geq p$  by ( $\Theta$ ). Note the concluded event is stronger than the safety formula's truth set: the chain never fails and never leaves the modelled domain. Leaving counts as failure — that is the fail-closed reading, and it is what (R4) is recomputed for.  $\square$

**Proposition R40.7** (soundness of `QSafetyBattery`). *Under the hypotheses above including the formula tie (F): for every  $x \in D$  with  $V(x) \leq y$ ,  $\Pr_x^*[\forall n, \text{sat}(\omega_n)] \geq p \rightarrow$  the concluded satisfaction judgment  $\mathcal{M}, x_0 \in \{V \leq y\} \models \text{SProbGE}(p, \text{PAlways } \varphi)$ , read on the sublevel region  $\{V \leq y\}$ .*

*Proof.* By the contrapositive of (F),  $\omega_n \in D \setminus U$  implies  $\text{sat}(\omega_n)$ ; so the event of Theorem R40.6 is contained in  $\{\forall n, \text{sat}(\omega_n)\}$ , and monotonicity of the (outer) measure finishes. No measurability is ever asked of the satisfaction predicate — the smaller, fail-closed event is the measurable one.  $\square$

**Remark R40.8** (why the floors are not decoration). Drop (B3) and take  $V \equiv 0$ : drift, nonneg, and threshold rows all hold, with  $V(x) = 0 \leq y$  for any  $y \geq 0$ , so with  $y = 0$ , (Θ) permits  $p = 1$ : the rule would certify *almost-sure* safety — of any chain at all, including the two-state chain  $D = \{d\}$ ,  $U = \{u\}$ ,  $K d = \delta_u$ , which fails at its first step. With the floor present, this certificate dies immediately: (B3) forces  $V(u) \geq 1$ , and then the generator row at  $d$  demands  $\int V dK d = V(u) \leq V(d) = 0$  — contradiction. Failure must cost at least one unit of certificate value; the floor is the price list.

**Remark R40.9** (why the nonnegs are not decoration). The maximal inequality of Lemma R40.3 is *false* for signed supermartingales, and a two-branch chain isolates the sign hypothesis exactly — every other row intact, boundedness included. Take  $D = \{s, b\}$ ,  $U = \{a\}$ ,  $\bar{D} = \{s, a, b\}$ , with  $K s = \frac{1}{2}\delta_a + \frac{1}{2}\delta_b$ ,  $K b = \delta_b$ , and the signed certificate  $V(s) = 0$ ,  $V(a) = 1$ ,  $V(b) = -1$ . The generator row holds on  $D \setminus U$  ( $\int V dK s = 0 \leq 0$ ;  $\int V dK b = -1 \leq -1$ ), the floor holds on  $U \cap \bar{D}$ , the hull and fail-closed rows hold, and  $|V| \leq 1$ . Were Proposition R40.4 available without nonnegativity, the certificate would conclude  $\Pr_s[\text{reach } a] \leq V(s) = 0$  — but the chain reaches  $a$  with probability  $\frac{1}{2}$ : the  $a$ -branch's barrier visit is subsidized by the mass parked at  $V = -1$  on the other branch, and (B4) is what forbids the loan. The classical unbounded picture is the simple symmetric random walk on  $\mathbb{Z}$  with  $V(z) = z$  and  $A = \{1\}$  — same phenomenon, though as a drop-one witness it is impure: it violates the boundedness hypothesis along with the sign, which is why the two-branch chain is the recorded counterexample.

**Remark R40.10** (the hull and fail-closed conditions (R3), (R4)). Both are recomputed by the checker, never taken from the producer, and each blocks a distinct hole. Without (R3), the one-step integral in the generator row could consult states outside  $\bar{D}$  — states where the floor and nonneg rows were *never checked* — and Lemma R40.5(iv)'s clamp-invisibility computation collapses. Without (R4), one-step mass could leave  $D \cup U$  entirely: the concluded event counts leaving the modelled domain as failure, and (R4) is exactly what makes the clamped certificate's drift hold at the *enlarged* stop set  $U \cup D^c$  — the design that let every hypothesis in Lemma R40.2 stay pointwise. A companion condition (floor-scope resolution) is discharged at row-compilation time: it is what makes the checked floor rows imply (B3) as stated here, and it has no semantic residue at this layer.

**Remark R40.11** (threshold and integrability). (Θ) is bookkeeping, and it is sharp: the certificate buys  $\Pr[\text{fail}] \leq y$ , so asserting success  $\geq p$  requires  $p \leq 1 - y$ , and  $y = 1 - p$  is the tightest admissible choice — producer weakening ( $y < 1 - p$ ) is sound for free. The integrability half of (B1 $\wedge$ B2) is the discrete-profile reading of “the certificate lies in the generator's domain”; for the intended instances — polynomial  $V$ , one-step images inside the compact hull by (R3) — it is automatic.

**Remark R40.12** (**profile** — what is proven, at which presentations). Proven, and quoted above this proof: the discrete-kernel profile — one-step Markov kernel semantics over the trajectory construction, the theorems `sound_QSafetyBattery` and `sound_QSafetyBattery_failClosed`, sorry-free. Also proven, end-to-end: the *PDMP sub-profile* of the continuous-time semantics — piecewise-deterministic flow with guarded jumps, no diffusion (`sound_GSHS_safety_battery`). And proven, at the profile that carries the general continuous-time semantics, jump-diffusions included: the *martingale-problem profile* — the system presented by its generator drift data,  $\mathcal{AV}$  carried as data beside the certificate with the martingale-problem hypothesis for the pair, càdlàg paths per the presentation — the theorems `sound_GSHS_safety_mp` and `sound_GSHS_safety_battery_mp`, machine-checked sorry-free in the semantic-universe strand's auxiliary package (module `QtsLAux.LayerD.MPDDischarge`). The three ingredients an earlier edition of this remark filed as missing are each discharged there: continuous-time generator domains ride the presentation — for the calculus's own denoted class, compositional symbolic piecewise-polynomial hypernets,  $\mathcal{AV}$  is again polynomial data and domain bookkeeping dissolves; fine path properties ride the presentation's càdlàg clause; and optional stopping for right-continuous nonnegative supermartingales is a library theorem, consumed at the exit début (`OptionalSamplingRC`, with `supermartingale_of_compensator_nonpos` and the exponential-discount construction). The epistemic shape is the discrete profile's own: exactly as the staged theorem quantifies over systems whose compilation satisfies the mixture bridge, the martingale-problem theorems quantify over systems whose presentation satisfies the martingale-problem hypothesis — an explicit bridge carried as data, never a silent assumption, so the argument this section walks is now the theorem's own at every profile. The martingale-problem theorems live in the semantic-universe strand's auxiliary package, which is registered with this catalogue's binder: their statements are extracted and hash-bound like every other block in this section, so the dashboard row carries no conditional mark — each named profile is proven, and its theorems are bound.

**Remark R40.13** (the staged premise shapes and the system bridge). The rule's node presents its premises per mode and per jump: mode-indexed certificate family ( $V_m$ ), interior rows against each mode's flow mechanism, guard rows per jump, floors and nonnegs per mode, and the threshold row in exact rational arithmetic, cast once. The bound theorem for that shape (`sound_QSafetyBattery_staged`) closes the gap to the flattened hypotheses used above through an explicit bridge hypothesis: at every in-scope state, the one-step kernel decomposes as a sub-convex mixture of the mode's flow step and the enabled guard-reset jumps (weights supported on enabled jumps). Under that decomposition the mode's interior row and the enabled guard rows are the flattened generator row (`mixture_drift`): the one-step integral splits over the mixture, each jump term is a guard row evaluation, and the weights sum to one. What stands left of the concluded  $\models$  is any system presentation whose compilation at this profile satisfies the bridge.

**Remark R40.14** (relation to the literature). Supermartingale safety certificates for stochastic systems go back to Kushner [147]; the modern certificate-form idiom — synthesize a barrier function, check polynomial rows, conclude a probability bound — is

Prajna–Jadbabaie–Pappas [202]. The probability engine is Ville's inequality [234], with the systematic supermartingale treatment in Doob [64]. The reading of the interior rows as one-step expected decrease is the Foster–Lyapunov drift idiom [181], whose geometric form powers the deadline sibling. What this rule adds to that literature is not mathematics but *trust structure*: every analytic ingredient lives in a verified lemma, every polynomial ingredient is an inherited base-calculus row replayed by the kernel, and the checker recomputes the side conditions rather than trusting the producer.

## Rule 41. QDEADLINEBATTERY (core rule)

### The rule (Steele metanotation)

as realized in the mechanized development; source row: `QTSL-rules.toml` — *QDeadlineBattery*. The metanotation statement is typeset by hand for notational quality; its mechanized ground truth is the Lean statement below, extracted from the sources at every build of this book and hash-bound. The rule *roster* is machine-checked (every mechanized rule tag round-trips to exactly one catalogue row); the statement *text* is editorial, checked by eye against the extracted Lean beside it.

$$\frac{\begin{array}{l} V : \text{QCertFam} \quad R \subseteq \llbracket \varphi \rrbracket \text{ (target formula tie)} \quad \{D_m \setminus R \vdash \mathcal{A}_m V_m \leq -\theta V_m\}_m \text{ (decay)} \\ \{\text{slab}_j \vdash g_j \ ; \ V_{m'_j} \leq V_{m_j}\}_j \text{ (guards, per jump } j: \text{ source mode } m_j, \text{ target } m'_j, \text{ reset } g_j) \\ \{\bar{D}_m \setminus R \vdash V_m \geq 1\}_m \text{ (floors, off-target only)} \quad \{\bar{D}_m \vdash V_m \geq 0\}_m, \{\bar{D}_m \vdash V_m \leq M\}_m \text{ (nonnegs; bound)} \\ \vdash q \leq \sum_{k \leq n} (\theta T)^k / k! \text{ (one TAYLORBOUND leaf)} \quad 0 \leq \beta, \beta \leq e^{-\theta}, \theta \geq 0, 0 \leq q, p \leq 1 \text{ (drift tie; sign gates)} \end{array}}{\mathcal{M}, x_0 \in \{V \leq (1-p)q\} \models \text{SProbGE}(p, \text{PDeadline}(T, \varphi, b))}$$

rule sort baked in theory `qtsl (QDeadlineBattery; the tabular tier's QDeadlineTable beside it)` — the display is the realized form, as the discrete-profile theorems bind it. A region left of the turnstile scopes the row  $(R \vdash P: P \text{ at every point of } R)$ ; the certificate family  $V$  enters as certificate data — a shared reference with no claim content of its own; the rows impose every claim — never as a derivation edge. In the drift tie and sign gates, both transcendental sides ( $\beta \leq e^{-\theta}$  and the Taylor leaf's  $e^{\theta T}$  enclosure) live in the soundness lemma, never in the checker. The conclusion is the region-conditioned judgment in constructor vocabulary, as at `QSAFETYBATTERY`;  $b$  is `PDeadline`'s producer-chosen-horizon mark.

**QDEADLINEBATTERY** is the bounded-reachability battery: it concludes that with probability at least  $p$  the system reaches the target — satisfies `PDeadline( $T, \varphi, b$ )` (surface syntax  $F_{\leq T} \varphi$ ) — from every start in the sublevel region  $\{V \leq (1-p)q\}$ . Its engine is exponential decay: decay rows say the certificate shrinks by a factor  $\beta$  per step off the target, so the discounted process  $\beta^{-t}V$  is a supermartingale off the target, while the off-target floor  $V \geq 1$  makes *missing* the deadline cost at least one unit of discounted certificate value; Markov's inequality at the horizon gives  $\Pr[\text{miss}] \leq \beta^T V(x)$ .

The rule's division of labour between checker and lemma is its most instructive feature. The checker replays only exact rational comparisons: the one arithmetic leaf is the Taylor comparison  $q \leq \sum_{k \leq n} (\theta T)^k / k!$  — a closed, wire-free inequality discharged by the ground-fact rule — while both transcendental facts ( $\sum_{k \leq n} (\theta T)^k / k! \leq e^{\theta T}$  and  $e^{-\theta} e^{\theta} = 1$ ) live inside the soundness lemma. The checker never needs to know  $e$  exists.

What the checker recomputes beyond that leaf: the domain-hull and fail-closed side conditions (as in the safety battery), and the threshold arithmetic in the exact rational vocabulary ( $\text{thr}_F = \text{thr} \cdot q \text{ atop } p + \text{thr} \leq 1$ ). Soundness is independent of the producer knobs  $\theta$  and  $q$ : any discrete rate  $0 \leq \beta \leq e^{-\theta}$  and any  $q$  below the Taylor sum are admissible.

Each hypothesis is load-bearing. Drop the off-target floor and a certificate identically 0 would certify certain reachability of an unreachable target. Drop the boundedness row and the decay row no longer transfers to the clamped certificate — the discount multiplies the certificate by  $\beta^{-t}$ , so the ceiling must be invisible wherever one-step mass reaches, which is exactly what  $V \leq M$  buys (and, in the mechanized engine, the integrability of the discounted certificate rides the same bound). Drop the fail-closed containment and escape from the modelled domain would count as success: a reach guarantee must show the escape event *null*, where the safety battery could simply enlarge its stop set (leaving counts as failing is conservative for safety, but would be unsound generosity for reachability). Drop the threshold arithmetic and the concluded region over-budgets. The proof section walks each.

The dashboard mark states the status: the hash-bound theorems warrant the rule at the discrete-kernel profile (geometric drift,  $\beta = e^{-\theta}$  discretized); the continuous-time profile is proven at the martingale-problem presentation — the discounted supermartingale built from the undiscounted martingale-problem hypothesis by the exponential-discount construction, stopped at the début by the right-continuous optional-sampling library theorem (`sound_GSHS_deadline_mp`, `sound_GSHS_deadline_battery_mp`, `QtslAux.LayerD.MPD`ischarge) — hash-bound below via the `qtsl-aux` package registration, so the dashboard row carries no conditional mark: each named profile is proven, and its theorems are bound.

At the general stratum, over the semantic universe's record carrier (the semantic-universe functor package, hash-bound below), the deadline conclusion is a *mark* — an  $\exists$ -face spec: the per-window family of acceptance-event demands is persistent, and satisfaction forces almost-sure acceptance at the window (`satAtM_acceptanceSpecF_ae`). The backward direction is deliberately absent, and the absence is the semantics: a record that reaches its target only in a superwindow is invisible to the subwindow, so a subwindow's reach demand is a genuinely stronger demand — a deadline — and extension is exactly how a met deadline persists to every superwindow. The measurability the mark face charges is issued by the site's topology rather than assumed: hit-events commute with countable unions in the set argument (`hitEvent_iUnion`), turning grid decompositions into event decompositions, and a compact target cell's visit event over a  $\sigma$ -compact stage window is Borel (`measurableSet_hitEvent_univ_prod_of_isCompact`). One typing note rides the transposition: the site-general grids are indexed by bare naturals; at clocked continuum strata the legs re-type to rational-duration stage cuts — the tick-indexed reading of a windowed horizon is a forcing of the finitary record site, not of the grammar.

**notes** The checked floor is *off-target only*: on the target the certificate may take any value, since success needs no budget. This is deliberately weaker than a global floor, and the proven statement binds the weaker form; a catalogued rendering that states a global floor is sound but relaxable

to match. The concluded threshold  $(1 - p)q$  is the compile's choice; the underlying theorem consumes only the single inequality  $\beta^T \cdot \text{thr} \leq 1 - p$ . At this profile, guard rows land inside the one-step decay row (the kernel carries flow and jumps together); the instantaneous-jump reading, where the discount factor does not tick during a jump, is carried at the continuous-time profile by the martingale-problem discharge's no-alarm segment assembly.

## Lean statement

BernsteinLogicAux.Battery . **sound\_QDeadline**

statement bound

```
/-- **`sound_QDeadline`, discrete profile** (T6): over the target-hit form, the deadline
formula tie – the target region *under*-approximates the truth set of the
`F_{≤T}`-argument – weakens the concluded event to the truth of the reach formula:
`Pr_x[∃ t ≤ T, X t = φ] ≥ p` on the concluded region `D n {V ≤ thr}`. No measurability
is asked of the satisfaction predicate (`measure_mono` on the measurable hit event). -/
theorem sound_QDeadline {T : ℕ} {M : ℝ} {sat : S → Prop}

```

The catalogue form: the  $(\theta, q)$  parameterization, concluding on  $\{V \leq (1 - p)q\}$  from the Taylor leaf and the drift tie  $\beta \leq e^{-\theta}$ , with both transcendental facts inside the lemma. It is a wrapper over `sound_QDeadline`, which carries the general inequality form  $\beta^T \cdot \text{thr} \leq 1 - p$ .

BernsteinLogicAux.QtslBattery . **sound\_QDeadlineBattery**

statement bound

```
/-- **`sound_QDeadlineBattery`** (QTSL-rules.toml row `QDeadlineBattery` –
the catalogue's  $(\theta, q)$  parameterization of T6, discrete-kernel profile).
```

The concluded region is  $\{V \leq (1 - p) \cdot q\}$ : the deadline threshold  
 $\text{thr}_F = \text{thr} \cdot q$  in the staged  $\text{q\_mul}$  vocabulary atop  $\text{thr} = 1 - p$ .  
 Its arithmetic premises are

- \* the **\*\*T7 Taylor leaf\*\***  $q \leq \sum_{k \leq n} (\theta T)^k / k!$  – the one closed wire-free comparison the checker replays in exact  $\mathbb{Q}$  (rule row  $\text{TaylorBound } (T7)$ , alias  $\rightarrow \text{PConstExact}$ ), and
- \* the **\*\*drift tie\*\***  $\beta \leq e^{-\theta}$  – the producer's discrete geometric rate matching the catalogue's  $\beta = e^{-\theta}$  (any smaller rate is sound).

The transcendental facts –  $\sum_{k \leq n} (\theta T)^k / k! \leq e^{\theta T}$  ( $\text{Real.sum\_le\_exp\_of\_nonneg}$ ) and  $e^{-\theta} \cdot e^{\theta} = 1$  – live in this lemma, never in the checker (the catalogue's "the checker never needs to know  $e$  exists"). Wrapper over  $\text{sound\_QDeadline}$ , which carries the general inequality form  $\beta \wedge T \cdot \text{thr} \leq 1 - p$ .

System bridge: for any System whose chart compilation at the discrete-kernel profile yields  $K$ , this is the concluded  $\text{QRegionSat}$ 's reading on that System's records. -/

```

```

**The general-stochastic instance, assembled.** The deadline bound on the timed skeleton of the segment model: the  $\theta$ -discounted generator rows enter per segment, the clock is a coordinate of the timed chain, and the conclusion is the displayed deadline-overrun bound on that chain's events — headline, off-target, and battery forms.

BernsteinLogicAux.LayerD.Deadline . **sound\_GSHS\_deadline**

statement bound

```
/-- **The GSHS deadline tail bound** (T6, headline form). Inherited
premises, stated (the leg's discipline – never silent):

* `hSegD : SegmentDynkin M θ V` at the discount `θ` – **the  $\theta > 0$  premise**:  

  the B1 row compiled at positive discount; the  

  statement is typed at  $\theta \leq \theta$  and degenerates to the trivial floor bound  

  at  $\theta = 0$ .

* `hFloor : ∀ y, ε ≤ V y` – **the F7 floor premise**:  

  the positive floor on the working region, conclusion scaled by  $1/\epsilon$ .  

  Without it the conclusion is unsound (the review's two-point witness:  $V \equiv 0$   

  off-target satisfies every remaining hypothesis while the deadline fails  

  surely).
```

Conclusion: the probability that the timed skeleton chain ever presents a value stamped past the deadline  $T$  is at most  $e^{-\theta T} V(x)/\epsilon$  – the T6 display  $\text{Pr}[\tau_B > T] \leq e^{-\theta T} V(x_0)/\epsilon$  in the value-presentation reading: instantiated at the stopped presentation  $\text{Rep}(P^{\{tB\}})$  with halts into the target ("the stop IS the target" – a design choice made here and visible), a path outside this event either reached the target by  $T$  or stalled (Zeno / vanished – the residues emptied a.s. for in-scope models by the prose W-Z-freedom theorem). Consumes  $\text{Battery.measure\_reach\_le}$  (=  $\text{Ville.reach\_avoid}$ ) over the

```

timed chain: the deadline battery rides literally the same engine as T5,
with the capped certificate  $\min(e^{\{0s\}V}, \epsilon e^{\{0T\}}/\epsilon e^{\{0T\}})$  – and no
global bound  $V \leq C$  is demanded (the cap manufactures its own). -/
theorem sound_GSHS_deadline [IsMarkovKernel M.seg] [IsMarkovKernel M.jump]

    ≤ ENNReal.ofReal (Real.exp (-(θ * T)) * V x / ε)

```

BernsteinLogicAux.LayerD.Deadline . **sound\_GSHS\_deadline\_offTarget**

statement bound

```

/-- **T6, off-target-floor variant** (the sharper premise, the narrower
event): the floor is demanded off the target only – the F7 floor premise
read narrowly – and the conclusion event asks for a past-deadline
presentation *outside* `B`. What this variant gives up is the crossing-jump
corner: a path whose first past-`T` presentation is the target hit itself
(the dispatch that crossed the deadline landed in `B`) misses the deadline
without entering this event – `exceed_cases` makes the dichotomy explicit.
The headline `sound_GSHS_deadline` closes the corner by flooring the whole
working region instead. -/

**The general stratum: grid tickets by topology.** The countable-combination engine and the reach leg's measurability ticket over the record carrier: hitting commutes with unions in the set argument, and a compact target cell's visit event over a  $\sigma$ -compact stage window is Borel — issued by the site's topology, not assumed.

SuFunctor.Site.FellAcceptance . **hitEvent\_iUnion**

statement bound

```

/-- **Hitting commutes with unions in the set argument** — the engine
that turns countable set decompositions into countable event
decompositions. Arbitrary index, pure set algebra. -/
theorem hitEvent_iUnion {ι : Sort*} (A : ι → Set α) :
  hitEvent (⋃ i, A i) = ⋃ i, hitEvent (A i)

```

## Correspondence (Steele display $\leftrightarrow$ Lean)

**a bound Lean statement CHANGED since certification — re-review and re-certify** The dictionary below is a reviewer-certified statement of how the mechanized statements above interpret the displayed rule: display metavariable  $\mapsto$  Lean binder, each display hypothesis  $\mapsto$  the premise or side condition carrying it, the display conclusion  $\mapsto$  the goal — with any deliberate difference in width between display and mechanization named outright. Certification is recorded as a hash triple over (the displayed cell, the extracted statement texts, this dictionary's own text); if any of the three changes, this block turns amber until a reviewer re-certifies. The correspondence claim itself remains editorial — reviewer-grade, not machine-checked; its machine-checked successor types each soundness statement against the rule as a structured object, and supersedes this block per rule as it lands.

Model frame and profile as at QSAFETYBATTERY: hash-bound at the discrete-kernel profile (the amended cell's own caveat), with the continuous-time profile proven at the martingale-problem presentation (hash-bound below, per the profile remark). The catalogue form binds sound\_QDeadlineBattery; sound\_QDeadline carries the general inequality it wraps.

- the displayed judgment  $\mathcal{M}, x_0 \in \{V \leq (1-p)q\} \models \text{SProbGE}(p, \text{PDeadline}(T, \varphi, b)) \mapsto$  the goal of  $\text{Real } p \leq \text{pathMeasure } K \times \{\omega \mid \exists k \leq T, \text{sat } (\omega \ k)\}$  from every start with  $x \in D$  and  $V \times \leq (1-p) \cdot q$ ; the target tie  $\mapsto \text{hF} : \forall y \in B, \text{sat } y \text{ — } B$  under-approximates the target truth set (the polarity opposite to QSAFETYBATTERY's avoid tie, both safe directions), and again no measurability is asked of sat.
- decay rows  $\mapsto \text{hdecay}$  (one-step  $\int V \leq \beta V$  on  $D \setminus B$ ; at this profile guard rows land inside it, per the note) with integrability rider hint; floors *off-target only*  $\mapsto \text{hfloor}$  (on  $\bar{D} \setminus B$  — the display's weaker, deliberately relaxable form is exactly what is bound); nonnegs  $\mapsto \text{hnonneg}$ ; the bound row  $V \leq M \mapsto \text{hM}$ .
- the TaylorBound leaf  $q \leq \sum_{k \leq n} (\theta T)^k / k! \mapsto \text{hq}$ , verbatim — the one closed comparison a checker replays in exact  $\mathbb{Q}$  — and the drift tie  $\beta \leq e^{-\theta} \mapsto \text{h}\beta\theta$ , with both transcendental facts ( $\text{Real.sum\_le\_exp\_of\_nonneg}$ ;  $e^{-\theta}e^\theta = 1$ ) discharged *inside* the lemma: the certified statement is the witness that the checker never needs to know  $e$  exists.
- sign gates  $0 \leq \beta, \theta \geq 0, 0 \leq q, p \leq 1 \mapsto \text{h}\beta/\text{h}\theta/\text{hq}/\text{hp}$ , verbatim — the base sign gate  $\text{h}\beta$  is consumed by the power-order step; side conditions and region measurability as at QSAFETYBATTERY ( $\text{hR3}/\text{hR4}$ ;  $\text{hD}/\text{hDbar}/\text{hB}/\text{hV}$ , the undisplayed regularity pack).

Width note: the wrapped sound\_QDeadline consumes only  $\beta^T \cdot \text{thr} \leq 1 - p$  — every  $(\theta, q)$  satisfying the displayed leaves yields it, so the catalogue parameterization is an instance of a strictly wider certified core; producer knobs, exactly as the roster note says.

## Lean verifier receipts

module BernsteinLogicAux.Battery; bound build 2fd1c031c80b... (bound from receipt 8d9ccb68993ea0ec, 2026-08-04T01:56:55Z). A receipt records that named checking layers accepted a build: (module, compiled-artifact SHA-256, environment SHA-256, checker layers), minted when the checking gate ran; the store receipts attesting the bound build are listed with the layers each run credited. Nothing here asks the reader to trust the store: every layer is an independently runnable program over the quoted sources — rebuild the module and re-run the checkers to reproduce the verdict. Receipts attesting superseded builds credit no layer and are omitted from this rendering (the count of omissions, if any, is noted below).

| receipt          | minted               | layers             | status  |
|------------------|----------------------|--------------------|---------|

#### gate-layer coverage of the bound build:

build (lake build (elaboration)) current

replay (leanchecker (official kernel replay)) stale only

hardened (safe\_verify (hardened screen)) stale only

decorrelated (lean4export + nanoda (decorrelated kernel)) current

**comparator:** none no fixture in the three-implementation comparator harness (compiled / kernel-interpreted / reference-interpreted) exercises this rule.

## HOL4 statement

### NO HOL STATEMENT YET

The HOL4 development ports the base calculus's checker chain (theory `bern_catalogue`, developed side by side with the base catalogue sources, stopping below the proof-object layer); it contains no probability or measure theory. QDEADLINEBATTERY lives one theory-extension edge above the base calculus and its soundness content is path-space measure theory (discounted supermartingales, optional stopping, an escape-null argument), for which no counterpart exists anywhere in the ported development. A HOL statement of this rule would be a new measure-theoretic campaign, not an extension of the ported checker chain; until one exists, this box is the honest state of the edifice.

## HOL verifier receipts

### NONE

no HOL verification receipt exists for this rule.

## Proof

Genre: core rule (tier 1) — an ordinary mathematical proof at Putnam-exam-solution detail. Substrate, stopped-process machinery, and the battery pattern are stated with QSAFETYBATTERY (Lemmas R40.1–R40.3, Proposition R40.4) and cited here by reference. The theorems quoted above warrant the rule at the discrete-kernel profile; the profile remark at the end states what remains a hypothesis beyond it.

**Setting and claim.** The substrate of QSAFETYBATTERY: state space  $S$ , one-step Markov kernel  $K$ , path measure  $\Pr_x$ , canonical filtration. The rule's data: modelled domain  $D$ , hull  $\bar{D} \supseteq D$ , a target  $B$  compiled to *under*-approximate the truth set of the  $F_{\leq T}$ -argument — note the orientation flip against the safety battery's avoid set: the formula tie here is  $(F') \forall y \in B, \text{sat}(y) \rightarrow$  a measurable certificate  $V$ , a discrete decay factor  $\beta \geq 0$ , a horizon  $T \in \mathbb{N}$ , and  $p, \text{thr}$ . The checked rows, read semantically:

- (D1) *decay*: for  $y \in D \setminus B$ ,  $V$  integrable against  $K y$  and  $\int V dK y \leq \beta V(y)$  — the discrete reading of  $AV \leq -\theta V$  with  $\beta = e^{-\theta}$ . (At this profile guard rows land inside this one row; see Remark R41.8.)
- (D2) *floor, off-target*:  $V \geq 1$  on  $\bar{D} \setminus B$ .
- (D3) *nonneg*:  $V \geq 0$  on  $\bar{D}$ ; *bound*:  $V \leq M$  on  $\bar{D}$ .
- (R3)/(R4) *hull and fail-closed containment at target  $B$* : from  $y \in D \setminus B$ , one-step mass stays in  $\bar{D}$  and in  $D \cup B$ .
- ( $\Theta_F$ ) *deadline threshold*:  $\beta^T \cdot \text{thr} \leq 1 - p$ .

The claim (`sound_QDeadline`): for every  $x \in D$  with  $V(x) \leq \text{thr}$ ,

$$\Pr_x^*[\exists k \leq T, \text{sat}(\omega_k)] \geq p$$

— outer measure, as everywhere in the family: no measurability is asked of the satisfaction predicate, and the mark is inert whenever its truth set is measurable.

**Lemma R41.1** (discounted tail bound at the enlarged target). *Let  $B' := B \cup D^c$ . Under (D1)–(D3), (R3), (R4): for every  $x \in D \setminus B$ ,*

$$\Pr_x[\forall k \leq T, \omega_k \notin B'] \leq \beta^T V(x).$$

*Proof.* Clamp as in the safety battery, but with the floor forced on  $D \setminus B$  rather than off  $D$ : let  $C := \max(M, 1)$  and let  $g$  clamp  $\max(V, 1)$  into  $[0, C]$  on  $D \setminus B$  and  $\max(V, 0)$  into  $[0, C]$  elsewhere. As in Lemma R40.5:  $0 \leq g \leq C$ ;  $g \geq 1$  off  $B'$  (here the floor (D2) does the work on  $\bar{D} \setminus B$ , and the forced branch covers the rest); on  $\bar{D} \cap (D \cup B)$  — which carries all one-step mass from  $D \setminus B$ , by (R3)+(R4) — the clamp is invisible,  $g = \min(V, C)$ . And by the bound row (D3),  $V \leq M \leq C$  on the hull, so the ceiling never truncates there:  $g = V$  on the whole mass-carrying set and at  $y$  itself. The decay row therefore transfers,  $\int g dK y = \int V dK y \leq \beta V(y) = \beta g(y)$  for  $y \in D \setminus B$  — and this is where the bound row is load-bearing, not an integrability convenience: without it the transfer would need  $\min(\beta V(y), C) \leq \beta \min(V(y), C)$ , false for  $0 < \beta < 1$  wherever  $V > C$  (at  $\beta = 0$  both sides vanish; that branch is handled separately below). Likewise  $g(x) = V(x)$ . Assume first  $\beta > 0$ . Now the discounted process  $M_n := \beta^{-(n \wedge \tau_{B'})} g(\omega_{n \wedge \tau_{B'}})$  is a nonnegative supermartingale (the decay row supplies exactly the extra factor  $\beta$  the discount consumes at each surviving step), and on the miss event  $\{\forall k \leq T, \omega_k \notin B'\}$  we have  $\tau_{B'} > T$  and  $g(\omega_T) \geq 1$ , so  $M_T \geq \beta^{-T}$ . Markov's inequality at time  $T$  gives  $\Pr[\text{miss}] \leq \beta^T \mathbb{E} M_0 = \beta^T g(x) = \beta^T V(x)$ . For  $\beta = 0$  the inverse discount is unavailable and the bound holds directly: at  $T = 0$  the right side is  $V(x) = g(x) \geq 1 \geq \Pr[\text{miss}]$  (the floor off  $B'$ ), while for  $T \geq 1$  the decay row at  $\beta = 0$  forces  $\int g dK_y = 0$  for every  $y$  off  $B'$ , so —  $g \geq 1$  off  $B'$  — the kernel from any off- $B'$  point charges  $B'$  with full mass and the miss event is null, by the one-step marginal of the trajectory law — the same prefix-step disintegration Lemma R41.2 rides. The mechanized route packages this computation as the geometric-drift engine (the discounted supermartingale and its hitting-time moment bound), consumed at the enlarged target  $B'$ .  $\square$

**Lemma R41.2** (no escape). *Under (R4) at target  $B$ : for  $x \in D$ ,*

$$\Pr_x \left[ \exists n, (\forall k \leq n, \omega_k \notin B) \wedge \omega_n \notin D \right] = 0.$$

*Proof.* Write  $E_n$  for the event that some escape as displayed occurs by time  $n$ . Induction on  $n$  gives  $\Pr_x[E_n] = 0$  for every  $n$ . Base: coordinate 0 is deterministically  $x \in D$ . Step: an escape at time  $n + 1$  that has not yet visited  $B$  either already escaped by time  $n$  (null by the inductive hypothesis) or steps from a state in  $D \setminus B$  to a state outside  $D \cup B$  — and that step is null, because the joint law of the  $n$ -prefix and the next step disintegrates through the one-step kernel, at which (R4) says the section  $(D \cup B)^c$  has measure zero from every surviving prefix endpoint. The displayed event is  $\bigcup_n E_n$ , null as a countable union of null events. This lemma is the almost-everywhere invariance content of (R4) that a reach conclusion cannot avoid: the safety battery got fail-closure for free by enlarging its stop set — leaving counts as failing is conservative there — but a reach guarantee cannot count escape as success, so the escape event must be shown null outright.  $\square$

**Theorem R41.3** (target-hit form). *Under (D1)–(D3), (R3), (R4),  $(\Theta_F)$ : for every  $x \in D$  with  $V(x) \leq \text{thr}$ ,  $\Pr_x[\exists k \leq T, \omega_k \in B] \geq p$ .*

*Proof.* If  $x \in B$ , the deadline is met at time 0 almost surely (coordinate 0 is deterministic) and  $p \leq 1$  suffices — the degenerate corner, handled first so the clamp may assume  $x \notin B$ . Otherwise decompose the miss event:  $\{\text{miss } B \text{ through } T\} \subseteq \{\text{miss } B' \text{ through } T\} \cup \{\text{escape before visiting } B\}$ . The second is null (Lemma R41.2); the first has probability  $\leq \beta^T V(x) \leq \beta^T \text{thr} \leq 1 - p$  (Lemma R41.1 and  $(\Theta_F)$ ). Complement.  $\square$

**Proposition R41.4** (soundness of QDeadlineBattery). *With the formula tie  $(F')$ :  $\Pr_x^*[\exists k \leq T, \text{sat}(\omega_k)] \geq p$  for every  $x \in D$  with  $V(x) \leq \text{thr}$  — the concluded judgment read on the sublevel region.*

*Proof.*  $B$  under-approximates the truth set, so the hit event of Theorem R41.3 is contained in the reach-formula event; monotonicity of the (outer) measure. As always, no measurability is asked of the satisfaction predicate.  $\square$

**Proposition R41.5** (catalogue form: the  $(\theta, q)$  parameterization). *Suppose additionally  $\beta \leq e^{-\theta}$  with  $\theta \geq 0$  (the drift tie),  $0 \leq q \leq \sum_{k \leq n} (\theta T)^k / k!$  for some  $n$  (the Taylor leaf — the one closed, wire-free comparison the checker replays in exact rational arithmetic, discharged as a ground-fact-rule application), and  $p \leq 1$ . Then the conclusion of Proposition R41.4 holds on the region  $\{V \leq (1 - p)q\}$ .*

*Proof.*  $q \leq \sum_{k \leq n} (\theta T)^k / k! \leq e^{\theta T}$  — the first transcendental fact, living here and not in the checker, applied at the nonnegative exponent  $\theta T$  — and  $\beta^T \leq e^{-\theta T}$ , powers preserving order between nonnegative bases ( $0 \leq \beta \leq e^{-\theta}$ ,  $T \in \mathbb{N}$ ); so  $\beta^T q \leq e^{-\theta T} e^{\theta T} = 1$  — the second. Hence  $\beta^T \cdot (1 - p)q \leq 1 - p$ : hypothesis  $(\Theta_F)$  holds at  $\text{thr} = (1 - p)q$ , and Proposition R41.4 applies. The checker never needs to know  $e$  exists; soundness is indifferent to the producer knobs  $\theta$  and  $q$  — any smaller rate or budget is admissible.  $\square$

**Remark R41.6** (why the off-target floor is not decoration). Drop (D2) and take  $V \equiv 0$  with the identity kernel  $Ky = \delta_y$  at some  $x \in D \setminus B$ : decay holds ( $0 \leq \beta \cdot 0$ ), nonneg and bound hold, and  $(\Theta_F)$  permits any  $p \leq 1$  since  $\beta^T \cdot 0 = 0$ . The rule would then certify that a chain frozen forever outside the target reaches it with probability one. With the floor present the certificate dies:  $V \geq 1$  on  $\bar{D} \setminus B \ni x$  contradicts  $V(x) = 0$ . Missing the deadline must cost at least one unit of discounted certificate value — that is precisely the step  $M_T \geq \beta^{-T}$  in Lemma R41.1. And the floor is asked off the target only: on  $B$  the certificate may take any value, because success needs no budget. This checked form is deliberately weaker than a global floor, and the proven statement binds the weaker form.

**Remark R41.7** (the two intrinsic asymmetries against the safety battery). Both are consequences of concluding reach rather than avoid, and neither is an artefact of the mechanization. First, the boundedness row  $V \leq M$ : the safety battery's additive drift survives its ceiling for free —  $\int \min(V, C) dKy \leq \min(\int V dKy, C) \leq \min(V(y), C)$  — so a ceiling at  $\max(\text{thr}, 1)$  cost nothing; here the discount multiplies the certificate by  $\beta^{-n}$ , and the transfer of the decay row to the clamped certificate needs the ceiling to be invisible wherever one-step mass reaches — exactly (D3)'s bound, consumed inside Lemma R41.1 (and in the mechanized geometric-drift engine it additionally supplies integrability of the discounted certificate) — for polynomial certificates over a compact hull it is free. Second, escape: the safety battery counts leaving the modelled domain as failure by enlarging its stop set, which is conservative for an avoid conclusion but would be unsound generosity for a reach conclusion — hence Lemma R41.2, whose almost-everywhere argument is the one place this section's hypotheses stop being pointwise.

**Remark R41.8** (guards at this profile). The catalogued rule lists guard rows (jumps instantaneous). At the discrete-kernel profile the one-step kernel carries flow and enabled jumps together, so the guard rows land inside the single decay row (D1) — exactly as the safety battery's interior and guard rows land together. The instantaneous-jump reading — the discount factor does not tick during a jump, so the  $e^{\theta t}$  factor cancels across it — belongs to the continuous-time profile, where it is carried by the martingale-problem discharge of Remark R41.9.

**Remark R41.9** (profile — what is proven, at which presentations). Proven: the discrete-kernel profile, sorry-free (sound\_QDeadline\_hit, sound\_QDeadline, sound\_QDeadlineBattery). Also proven: the continuous-time profile at the martingale-problem presentation (sound\_GSHS\_deadline\_mp, sound\_GSHS\_deadline\_battery\_mp, module QtslAux.LayerD.MPDDischarge of the semantic-universe strand's auxiliary package) — and the three ingredients this remark once filed are exactly what that discharge supplies: the  $e^{\theta t}V$  supermartingale over continuous time is the exponential-discount construction from the undiscounted martingale-problem hypothesis; optional stopping for right-continuous nonnegative supermartingales is the library theorem, consumed at the début; and the instantaneous-jump reading rides the presentation's no-alarm segment assembly. The martingale-problem theorems are hash-bound by this catalogue's binder via the qtsl-aux package registration, as for the safety sibling, so the dashboard row carries no conditional mark — each named profile is proven, and its theorems are bound.

*Remark* R41.10 (relation to the literature). The engine is the geometric drift condition of the Foster–Lyapunov family [181]: expected decrease by a factor per step off the target, yielding exponential hitting-time tails. The discounted supermartingale and its optional-stopping consumption are classical [64]; the barrier mechanics are the same Ville-type argument [234] the whole family rides. The certificate-form packaging — exact rational rows, transcendental facts quarantined inside a verified lemma — is this calculus's contribution rather than the literature's.

## Rule 42. QUnionBound (core rule)

### The rule (Steele metanotation)

as realized in the mechanized development; source row: `QTSL-rules.toml` — *QUnionBound*. The metanotation statement is typeset by hand for notational quality; its mechanized ground truth is the Lean statement below, extracted from the sources at every build of this book and hash-bound. The rule *roster* is machine-checked (every mechanized rule tag round-trips to exactly one catalogue row); the statement *text* is editorial, checked by eye against the extracted Lean beside it.

$$\frac{\mu(E_1) \leq a \quad \mu(E_2) \leq b \quad \text{fail} \subseteq E_1 \cup E_2}{\mu(\text{fail}) \leq a + b}$$

rule sort baked in theory `Qtsl` — realized measure-generically (arbitrary measure; no profile residue). Packaged instance (the début decomposition, pure path-set algebra over sequence space): failure of  $(\varphi_s \cup_{\leq T} \varphi)$ , at stop set *Stop* and good-exit set *R*, is contained in  $\{\text{some first Stop-visit presents a bad state}\} \cup \{\text{no Stop-visit through } T\}$  — the containment the until battery cites as its  $\text{fail} \subseteq E_1 \cup E_2$  premise.

QUnionBound is the battery family's glue: from two probability bounds and an event decomposition it concludes that the sum of the budgets bounds the failure event —  $\Pr[E_1] \leq a$ ,  $\Pr[E_2] \leq b$ , and  $\text{fail} \subseteq E_1 \cup E_2$  give  $\Pr[\text{fail}] \leq a + b$ . Its semantic content is monotonicity plus subadditivity (Boole's inequality), stated over an *arbitrary* measure: the rule is profile-generic, and its instance at any system-semantics profile is the same lemma applied at that profile's path measure. Its dashboard row accordingly carries an unconditional check with no profile discharge even needed — there was never a profile residue to discharge (the battery siblings' rows earned theirs through the martingale-problem discharge; this one is measure-generic from birth).

The hypothesis  $\text{fail} \subseteq E_1 \cup E_2$  is where all the content concentrates. The rule is sound for *any* decomposition; the citing rule must justify the containment. The packaged instance — the one the bounded-until battery cites — is the début decomposition: failure of “stay safe until the target, by the deadline” is contained in  $\{\text{some first stop-set visit presents a bad state}\} \cup \{\text{no stop-set visit by the horizon}\}$ . That containment is pure path-set algebra over sequence space: no measure, no measurability, only the well-ordering of the time axis.

A producer rarely writes this node by hand; it appears where a composite temporal property splits its failure modes across two certificates, and what the checker recomputes at such a node is precisely the containment side of the decomposition (or it discharges it by citing the packaged path-set lemma). The same additivity doubles as the slack-composition device in assume-guarantee composition, where interface slack budgets add across a wiring — one lemma, two consumers.

Why core rather than admissible: there is nothing to unpack into. Subadditivity of measure is not derivable from the other battery rules; it is new — deliberately small — semantic content at the measure level, and keeping it a separate node keeps every consumer's soundness proof honest about where its additivity comes from.

notes Stated in two forms: an extended-nonneg form (the primitive), and a real-valued form in the shape battery bounds actually arrive (certificate initial values), whose nonnegativity hypotheses are free at every use site.

### Lean statement

BernsteinLogicAux.QtslBattery . sound\_QUnionBound

statement bound

```
-- **`sound_QUnionBound`** ( $\mathbb{R}_{\geq 0\infty}$  form). Subadditivity through an event
decomposition — the entire semantic content of the `QUnionBound` rule
(QTSL-rules.toml row `QUnionBound`). -/
theorem sound_QUnionBound {Ω : Type*} [MeasurableSpace Ω] (μ : Measure Ω)
  {E₁ E₂ F : Set Ω} {a b : ℝ≥0∞}
  (h₁ : μ E₁ ≤ a) (h₂ : μ E₂ ≤ b) (hsub : F ⊆ E₁ ∪ E₂) :
  μ F ≤ a + b
```

BernsteinLogicAux.QtslBattery . sound\_QUnionBound\_ofReal

statement bound

```
-- **`sound_QUnionBound`** (`ENNReal.ofReal` form), in the shape the battery
bounds arrive: real-valued certificate bounds `a`, `b` combine to `a + b`.
The nonnegativity hypotheses are free at every use site (certificate initial
values, nonneg rows). -/
theorem sound_QUnionBound_ofReal {Ω : Type*} [MeasurableSpace Ω] (μ : Measure Ω)
  {E₁ E₂ F : Set Ω} {a b : ℝ} (ha : 0 ≤ a) (hb : 0 ≤ b)
  (h₁ : μ E₁ ≤ ENNReal.ofReal a) (h₂ : μ E₂ ≤ ENNReal.ofReal b)
  (hsub : F ⊆ E₁ ∪ E₂) :
  μ F ≤ ENNReal.ofReal (a + b)
```

BernsteinLogicAux.QtslBattery . compl\_firstExit\_subset

statement bound

```

/-- **The first-exit event decomposition** (the `QUnionBound` premise's
début decomposition): over
sequence space, the complement of the first-exit-success event — some time
`n ≤ T` whose state is in the good exit set `Good` with no earlier visit to
the stop set `Stop` — is contained in the union of {some `Stop`-visit is a
*first* visit presenting a bad state (`Stop \ Good`)} and {no `Stop`-visit
through `T`}. Pure path-set algebra, no measure and no measurability; the
until battery instantiates `Stop := (A ∪ R) ∪ D^c`, `Good := R`. This is the
lemma the `QUnionBound` premise `fail ⊆ E1 ∪ E2` cites for T8. -/
theorem compl_firstExit_subset {S : Type*} (Stop Good : Set S) (T : ℕ) :
  {ω : ℕ → S | ∃ n ≤ T, ω n ∈ Good ∧ ∀ j < n, ω j ∉ Stop}^c ⊆
  {ω : ℕ → S | ∃ n, ω n ∈ Stop \ Good ∧ ∀ j < n, ω j ∉ Stop} ∪
  {ω : ℕ → S | ∀ k ≤ T, ω k ∉ Stop}

```

## Correspondence (Steele display ↔ Lean)

**a bound Lean statement CHANGED since certification — re-review and re-certify** The dictionary below is a reviewer-certified statement of how the mechanized statements above interpret the displayed rule: display metavariable  $\mapsto$  Lean binder, each display hypothesis  $\mapsto$  the premise or side condition carrying it, the display conclusion  $\mapsto$  the goal — with any deliberate difference in width between display and mechanization named outright. Certification is recorded as a hash triple over (the displayed cell, the extracted statement texts, this dictionary's own text); if any of the three changes, this block turns amber until a reviewer re-certifies. The correspondence claim itself remains editorial — reviewer-grade, not machine-checked; its machine-checked successor types each soundness statement against the rule as a structured object, and supersedes this block per rule as it lands.

The cleanest dictionary in the Q-family — the certified statement is the displayed rule at full measure-generality, with no profile residue.

- $\mu \mapsto$  an arbitrary Measure  $\mu$  on an arbitrary measurable space — the amended display's own generality (*wider* than the original display's path-probability reading, in the safe direction): the rule's GSHS instance and the AG slack-composition use are the same lemma at other measures (the roster's “one item, two consumers”).
- the three premises  $\mu(E_1) \leq a$ ,  $\mu(E_2) \leq b$ ,  $\text{fail} \subseteq E_1 \cup E_2 \mapsto h_1, h_2, \text{hsub}$ , verbatim; conclusion  $\mu(\text{fail}) \leq a + b \mapsto$  the goal, verbatim. No hypothesis is unused and nothing undisplayed is demanded — not even measurability of the events (monotonicity and subadditivity hold for outer measure).
- the ofReal companion carries the same rule in the shape battery bounds arrive (real-valued  $a, b$ ), its two nonnegativity riders free at every use site, per the note.
- the packaged instance — the flavor text's début decomposition —  $\mapsto$  compl\_firstExit\_subset, certified alongside: pure path-set algebra over sequence space (no measure, no measurability), delivering exactly the  $\text{fail} \subseteq E_1 \cup E_2$  premise the until battery cites at  $\text{Stop} := (A \cup R) \cup D^c$ ,  $\text{Good} := R$ .

## Lean verifier receipts

module BernsteinLogicAux.QtslBattery; bound build 5c75f9923f27... (bound from receipt 3fd830b4914bdeda, 2026-08-04T01:56:58Z). A receipt records that named checking layers accepted a build: (module, compiled-artifact SHA-256, environment SHA-256, checker layers), minted when the checking gate ran; the store receipts attesting the bound build are listed with the layers each run credited. Nothing here asks the reader to trust the store: every layer is an independently runnable program over the quoted sources — rebuild the module and re-run the checkers to reproduce the verdict. Receipts attesting superseded builds credit no layer and are omitted from this rendering (the count of omissions, if any, is noted below).

| receipt          | minted               | layers             | status  |
|------------------|----------------------|--------------------|---------|
| 3fd830b4914bdeda | 2026-08-04T01:56:58Z | build+decorrelated | current |
| 96b18d8572451f65 | 2026-08-04T03:11:31Z | build+decorrelated | current |

13 further receipt(s) in the store attest superseded builds of this module and are omitted from this rendering.

### gate-layer coverage of the bound build:

build (lake build (elaboration)) current

replay (leanchecker (official kernel replay)) stale only

hardened (safe\_verify (hardened screen)) stale only

decorrelated (lean4export + nanoda (decorrelated kernel)) current

**comparator: none** no fixture in the three-implementation comparator harness (compiled / kernel-interpreted / reference-interpreted) exercises this rule.

## HOL4 statement

### NO HOL STATEMENT YET

The HOL4 development ports the base calculus's checker chain (theory `bern_catalogue`, developed side by side with the base catalogue sources, stopping below the proof-object layer); it contains no probability or measure theory. `QUNIONBOUND` lives one theory-extension edge above the base calculus, and even its small soundness content (measure subadditivity, a path-set decomposition over sequence space) has no counterpart anywhere in the ported development. A HOL statement of this rule would open a measure-theory development, not extend the ported checker chain; until one exists, this box is the honest state of the edifice.

## HOL verifier receipts

### NONE

no HOL verification receipt exists for this rule.

## Proof

Genre: core rule (tier 1) — the battery family's smallest member, and its only *measure-generic* one: the theorems below are stated over an arbitrary measure, so the rule carries no profile conditionality at all — its instance at any system-semantics profile is the same lemma applied at that profile's path measure. A Putnam grader would accept the one-line proof and then ask where the content went; the honest answer — into the decomposition hypothesis — is [Remark R42.4](#).

**Setting and claim.** Let  $(\Omega, \mu)$  be any measurable space with a measure, read throughout as the induced outer measure on arbitrary subsets (coinciding with  $\mu$  on measurable sets) — no measurability is asked of any event below, and both monotonicity and finite subadditivity hold in that reading. The rule: from  $\mu(E_1) \leq a$ ,  $\mu(E_2) \leq b$ , and a decomposition  $\text{fail} \subseteq E_1 \cup E_2$ , conclude  $\mu(\text{fail}) \leq a + b$ . In its battery consumption,  $\mu$  is the path measure  $\text{Pr}_x$  of the profile at hand,  $\text{fail}$  is the failure event of a composite temporal property, and  $a, b$  are the initial values of two certificates.

**Theorem R42.1** (soundness of `QUNIONBOUND`).  $\mu(E_1) \leq a, \mu(E_2) \leq b$ , and  $\text{fail} \subseteq E_1 \cup E_2$  imply  $\mu(\text{fail}) \leq a + b$ .

*Proof.* Monotonicity, then subadditivity (Boole's inequality):  $\mu(\text{fail}) \leq \mu(E_1 \cup E_2) \leq \mu(E_1) + \mu(E_2) \leq a + b$ . Note what is *not* used: no measurability of *any* of the three events (the Setting's outer-measure reading supplies monotonicity and finite subadditivity on arbitrary subsets), no disjointness of  $E_1, E_2$ , no probability normalization — the statement holds for any measure, which is exactly what makes the rule profile-generic.  $\square$

**Proposition R42.2** (real-valued form). *With  $a, b \geq 0$  real and the bounds given as  $\mu(E_i) \leq \text{ofReal-embedded budgets}$ , the conclusion is  $\mu(\text{fail}) \leq a + b$  under the same embedding.*

*Proof.* The embedding of nonnegative reals into extended nonnegative reals is additive on nonnegatives; apply Theorem [R42.1](#). This is the shape battery bounds actually arrive in — certificate initial values — and its nonnegativity hypotheses are free at every use site (certificate nonneg rows).  $\square$

**Lemma R42.3** (the *début* decomposition — the packaged instance). *Over sequence space  $S^{\mathbb{N}}$ , fix a stop set  $\text{Stop} \subseteq S$ , a good-exit set  $\text{Good} \subseteq S$ , and a horizon  $T$ . Then the complement of the first-exit-success event — some  $n \leq T$  with  $\omega_n \in \text{Good}$  and no earlier visit to  $\text{Stop}$  — is contained in*

$$\{\exists n, \omega_n \in \text{Stop} \setminus \text{Good} \wedge \forall j < n, \omega_j \notin \text{Stop}\} \cup \{\forall k \leq T, \omega_k \notin \text{Stop}\},$$

*i.e. in  $\{\text{some first Stop-visit presents a bad state}\} \cup \{\text{no Stop-visit through } T\}$ .*

*Proof.* Suppose the path is not a first-exit success. If it never visits  $\text{Stop}$  through  $T$ , the second disjunct holds. Otherwise some  $k \leq T$  has  $\omega_k \in \text{Stop}$ ; let  $n$  be the *least* index with  $\omega_n \in \text{Stop}$  (the well-ordering of  $\mathbb{N}$  — this is the entire “*début*” content; at continuous time the first-entry construction is a genuine theorem, while over  $\mathbb{N}$  it is a minimum). Then  $n \leq k \leq T$  and no  $j < n$  visits  $\text{Stop}$ ; were  $\omega_n \in \text{Good}$ , the path would be a first-exit success at  $n$  — contradiction. So  $\omega_n \in \text{Stop} \setminus \text{Good}$ , and  $n$  is a first visit: the first disjunct holds. No measure, no measurability, no topology was consulted — the lemma is pure path-set algebra.  $\square$

**Remark R42.4** (where the content lives). The rule is sound for *any* events  $E_1, E_2$ ; every gram of content sits in the hypothesis  $\text{fail} \subseteq E_1 \cup E_2$ , which the citing rule must justify and the checker must see justified. Drop it and the conclusion is unrelated to the premises — one could “bound” any event by any two budgets. In the bounded-until battery's use, Lemma [R42.3](#) is the justification, at  $\text{Stop} := (A \cup R) \cup D^c$  and  $\text{Good} := R$ : failure of “stay safe until the target, by the deadline” splits into a bad first exit (bounded by the avoid certificate) and no exit by the horizon (bounded by the deadline certificate). The split covers every failure: a failing path either never visits  $\text{Stop}$  through the horizon (the second disjunct) or has a first  $\text{Stop}$ -visit, which either is or is not a good landing — and a good landing, since  $R \subseteq \text{Stop}$  in this instance, is a success, so no third thing remains.

**Remark R42.5** (measure-genericity, stated sibling-aware). Within this book's battery family — safety, deadline, until, and this rule — the other three carry conditional marks (now recording, for safety, deadline, and until, that their continuous-time martingale-problem theorems are cited rather than hash-bound; see each profile remark); this rule alone is warranted unconditionally, because its statement never mentions a kernel, a path construction, or a filtration. The prediction this remark has carried since its first

edition held: the continuous-time discharges of the siblings consume these same two theorems verbatim — nothing here needed to be touched. (The *début* lemma is the sequence-space instance of its decomposition; a continuous-time consumer would supply its own first-entry construction — a genuine theorem there, as the lemma's proof notes — through those same transports.)

*Remark* R42.6 (the second consumer). The same additivity is the slack-composition device in assume-guarantee composition: when interface contracts compose across a wiring, their slack budgets add, and the addition is this rule's theorem applied to the composed failure events. One lemma, two consumers — which is the reason the rule is kept as a separate node rather than inlined into the until battery: every consumer's soundness proof stays honest about where its additivity comes from.

*Remark* R42.7 (why core, and why this small). There is nothing to unpack into: subadditivity of measure is not derivable from the other battery rules — each of them concludes a bound on a single certificate-shaped event from kernel rows, and none mentions two arbitrary events, let alone their union — so the rule cannot be admissible: it is new semantic content, deliberately minimal. Its smallness is a design decision inherited from the base calculus's taste: keep kernel-level content atomic, let composite rules be admissible unpackings over the atoms.

## Rule 43. QUNTILBATTERY (admissible rule)

### The rule (Steele metanotation)

as realized in the mechanized development; source row: `QTSL-rules.toml` — *QUntilBattery*. The metanotation statement is typeset by hand for notational quality; its mechanized ground truth is the Lean statement below, extracted from the sources at every build of this book and hash-bound. The rule *roster* is machine-checked (every mechanized rule tag round-trips to exactly one catalogue row); the statement *text* is editorial, checked by eye against the extracted Lean beside it.

$$\begin{array}{c}
 E_{\text{bad}} := \{\text{the first exit from } D \setminus (A \cup R) \text{ lands in } A \cup D^c\}, \quad E_{\text{miss}} := \{A \cup R \text{ not reached by } T\} \\
 \llbracket \neg \varphi_s \rrbracket \subseteq A, \quad R \subseteq \llbracket \varphi \rrbracket \text{ (formula ties)} \\
 \mu_x(E_{\text{bad}}) \leq V_a(x) \text{ (the QSafetyBattery slice for } V_a \text{ at stop set } (A \cup R) \cup D^c \text{; floor on } A \text{ only)} \\
 \mu_x(E_{\text{miss}}) \leq \beta^T V_d(x) \text{ (the QDeadlineBattery slice for } V_d \text{ at target } A \cup R) \\
 \llbracket \neg(\varphi_s \cup_{\leq T} \varphi) \rrbracket \subseteq E_{\text{bad}} \cup E_{\text{miss}} \text{ (the debut decomposition; consumed by QUnionBound)} \\
 0 \leq \beta, \quad 0 \leq V_d(x), \quad \beta^T \leq c \text{ (sign gates; rate tie)} \\
 \hline
 \mathcal{M}, x_0 \in \{V_a + c V_d \leq 1 - p\} \models \text{SProbGE}(p, \text{PUntil}(T, \varphi_s, \varphi))
 \end{array}$$

rule sort baked in theory `qtsl` (*QUntilBattery*, avoidance and target certificates as separate family fields), the concluded affine region atom (*qraAffine*) baked beside it — the display is the realized form, as the discrete-profile assembly binds it. The two slice premises are the sibling batteries' kits re-aimed — the avoid slice is the safety kit at the composite stop set with its floor asked on the bad exit  $A$  only, the deadline slice drives into  $A \cup R$  by the horizon — and each premise is the measure bound that slice's rows conclude; the rows themselves are the sibling entries' premises. Catalogue instance of the rate tie:  $c = q^{-1}$  with  $q \leq e^{\theta T}$ ,  $\beta = e^{-\theta}$  — fully rational at the discrete profile, no transcendental leaf. The conclusion is the region-conditioned judgment in constructor vocabulary, its composite region the baked *qraAffine* atom over  $V_a + c V_d$  at threshold  $1 - p$ .

*QUNTILBATTERY* concludes the bounded-until judgment  $\text{SProbGE}(p, \text{PUntil}(T, \varphi_s, \varphi))$  (surface syntax  $\text{P}_{\geq p}[\varphi_s \cup_{\leq T} \varphi]$ ) on a composite *affine* region *qraAffine*( $[(1, V_a), (c, V_d)], 1 - p$ ) — the sublevel set  $\{V_a + c V_d \leq 1 - p\}$  — from two certificates doing different work: an avoid certificate  $V_a$  guarding the safe-side formula  $\varphi_s$  until the target is reached, and a deadline certificate  $V_d$  driving the process into the target by the horizon. It is this catalogue's exemplar admissible rule at the satisfaction stratum: one node unpacks into two battery slices and one *QUnionBound* application, and the mechanized soundness proof is that unpacking — it consumes the deadline battery's theorem as a black box, applies the union bound once, and never re-proves either battery.

The two floors do different work, and the asymmetry is the rule's design.  $V_a$ 's floor is asked on the bad-exit set  $A$  *only* — the avoid certificate is silent on  $R \setminus A$ , so a landing there costs no certificate budget: the rule does not charge for winning (a landing in  $A \cap R$ , when the formula ties permit one, succeeds but is still priced as avoid-territory).  $V_d$ 's floor is on all of the hull off the target, exactly as its parent deadline battery demands. Fail-closed: leaving the modelled domain joins the stop set on the *bad* side, while an  $R$ -landing succeeds wherever it lands (the target's formula tie is global).

What the checker recomputes: the side conditions inherited from both battery slices, plus the one arithmetic hypothesis binding the slices together — the rate tie  $\beta^T \leq c$  on the affine atom's second coefficient. The catalogued instance  $c = q^{-1}$  with  $q \leq e^{\theta T}$  and  $\beta = e^{-\theta}$  satisfies the tie; at this profile the whole certificate is exact rational arithmetic, with no transcendental leaf (one becomes available by the deadline battery's Taylor-leaf pattern when  $\theta$ -rates are wanted). Drop the tie and the affine atom under-budgets the miss mass; drop either slice's rows and that slice's own counterexamples apply.

Tier, argued: admissible, not alias — three premise sub-derivations, not a respelling of one. And deliberately not monolithic core: a third self-contained lemma would duplicate two batteries' soundness; the mechanized assembly vindicates the choice by factoring through the named machinery instead. The dashboard mark states the status: hash-bound at the discrete-kernel profile; proven at the continuous-time martingale-problem profile (`sound_GSHS_until_mp`, `sound_GSHS_until_battery_mp`, `QtslAux.LayerD.MPDDischarge`) — hash-bound below via the `qtsl-aux` package registration, so the row carries no conditional mark: each named profile is proven, and its theorems are bound.

At the general stratum the until acceptance atom is stated over the semantic universe's record carrier directly (the semantic-universe functor package, hash-bound below): at some grid index the reach leg is hit and the avoid leg is missed (*untilEvent*) — a countable Boolean combination of hit-events, measurable from per-component tickets alone (*measurableSet\_untilEvent*). The clocked instantiation shape is recorded at the corollary: reach legs closed (a  $\leq$ -cut of stages times a closed target), avoid legs open (a  $<$ -cut times an open unsafe region) — and miss-events of open sets are measurable with no compactness anywhere. As at the deadline battery, the until conclusion is a mark ( $\exists$ -face): persistent by the same window-calculus engine, with the forward judgment lemma and the same deliberate absence of a backward direction — the deadline semantics the two batteries share.

notes The concluded region is the affine region atom with rows  $[(1, V_a), (c, V_d)]$  and threshold  $1 - p$  — an affine sublevel region over certificate values, the region-vocabulary generalization whose  $k = 1$  case is the ordinary sublevel atom.

### Lean statement

`BernsteinLogicAux.QtslBattery . sound_QUntilBattery`

statement bound

```

/-- **`sound_QUntilBattery`, discrete profile** (T8): over the first-hit
form, the two formula ties – `A` over-approximates the falsity set of the
safe-side formula ( $\neg \text{sat}_s y \rightarrow y \in A$ , the T13 OUTWARD direction), `R`
under-approximates the truth set of the target formula ( $\forall y \in R, \text{sat } y$ ) –
weaken the concluded event to the truth of  $\phi_s U_{\leq T} \phi$  along the path.
No measurability is asked of either satisfaction predicate (measure_mono
on the measurable first-hit event). -/

```

BernsteinLogicAux.QtslBattery. **sound\_QUntilBattery\_firstHit**

statement bound

```

/-- **`sound_QUntilBattery`, discrete profile, first-hit form** (the
catalogue's T8 row, fail-closed reading). The rule is
admissible over {T5, T6, `QUnionBound`}, and this proof *is* that unpacking:

```

```

* the T5 slice is `measure_firstBad_le` on the composite stop set
  `Stop := (A ∪ R) ∪ D^c` with the clamped avoid certificate `V_a` – floor
  rows on `A` only, drift rows off `A ∪ R` (the process is stopped at the
  target, so `V_a` is silent on `R`);
* the T6 slice is `measure_missTarget_le` at target `A ∪ R` with the
  deadline certificate `V_d` – global floor off the target;
* the glue is one `sound_QUnionBound_ofReal` application whose event
  decomposition is `compl_firstExit_subset`.

```

The concluded region  $\{V_a + c \cdot V_d \leq 1 - p\}$  with  $\beta \wedge T \leq c$  is the `qraAffine` atom (row `[(1, V_a), (c, V_d)]`, threshold `1 - p`); the catalogue's `c = q-1` with `q ≤ e{0T}`, `β = e{-0}` satisfies  $\beta \wedge T \leq c$  – the tie is dischargeable by the same T7 leaf pattern as `sound_QDeadlineBattery`. Fail-closed: leaving the modeled domain `D` before reaching `R` counts as failure (`Dc` joins the stop set on the bad side); reaching `R` counts as success wherever it lands, since the formula tie for `R` is global.

```

System bridge: for any System whose chart compilation at
the discrete-kernel profile yields `K`, this is the concluded
`QRegionSat`'s reading on that System's records, fail-closed form. -/

## Correspondence (Steele display $\leftrightarrow$ Lean)

**a bound Lean statement CHANGED since certification — re-review and re-certify** The dictionary below is a reviewer-certified statement of how the mechanized statements above interpret the displayed rule: display metavariable  $\mapsto$  Lean binder, each display hypothesis  $\mapsto$  the premise or side condition carrying it, the display conclusion  $\mapsto$  the goal — with any deliberate difference in width between display and mechanization named outright. Certification is recorded as a hash triple over (the displayed cell, the extracted statement texts, this dictionary's own text); if any of the three changes, this block turns amber until a reviewer re-certifies. The correspondence claim itself remains editorial — reviewer-grade, not machine-checked; its machine-checked successor types each soundness statement against the rule as a structured object, and supersedes this block per rule as it lands.

Model frame and profile as at QSafetyBattery (discrete-kernel; continuous time at the martingale-problem presentation, hash-bound below per the profile remark). One structural honesty first: the display presents the two battery slices by their *conclusions* — the measure bounds  $\mu_x(E_{\text{bad}}) \leq V_a(x)$  and  $\mu_x(E_{\text{miss}}) \leq \beta^T V_d(x)$  — plus the début containment that QUnionBound consumes, while the certified statement sound\_QUntilBattery takes the two slices' row families *inline* (flattened hypothesis lists over one kernel) and derives those bounds internally (the witness names the waypoints: `measure_firstBad_le`, `measure_missTarget_le`, with the containment bound as `compl_firstExit_subset`); the admissible-tier unpacking is realized by the *proof*, which consumes the QDeadlineBattery theorem as a black box, not by the statement's shape.

- the concluded judgment  $\mathcal{M}, x_0 \in \{V_a + c V_d \leq 1 - p\} \models \text{SProbGE}(p, \text{PUntil}(T, \varphi_s, \varphi)) \mapsto$  the goal of `Real p ≤ pathMeasure K × { $\omega \mid \exists n \leq T, \text{sat } (\omega \ n) \wedge \forall j < n, \text{sat}_s (\omega \ j)$ }` — the until event verbatim, both satisfaction predicates measurability-free.

- the two formula ties, opposite polarities (the QClosure directions), displayed as the inclusions  $\llbracket \neg\varphi_s \rrbracket \subseteq A$  and  $R \subseteq \llbracket \varphi \rrbracket$ :  $A$  *over*-approximates the falsity set of  $\varphi_s$  (hFs) and  $R$  *under*-approximates the truth set of  $\varphi$  (hFt) — the displayed inclusions verbatim, safe direction on both sides.
- the QSAFETYBATTERY slice for  $V_a$  (rows behind the displayed bound  $\mu_x(E_{\text{bad}}) \leq V_a(x) \mapsto \text{hVadriфт/hVaint}$  (drift at the composite stop set  $(A \cup R) \cup D^c$ , encoded as  $y \in D, y \notin A \cup R$ ),  $\text{hVafloor}$  — on  $A$  *only*, the display's "floor on  $A$  only" — and  $\text{hVannonneg}$ .
- the QDEADLINEBATTERY slice for  $V_d$  (rows behind the displayed bound  $\mu_x(E_{\text{miss}}) \leq \beta^T V_d(x) \mapsto \text{hVdecay/hVdint}$  ( $\beta$ -decay off  $A \cup R$ ),  $\text{hVdfloor}$  (global off-target),  $\text{hVdnonneg}$ ,  $\text{hVdM}$ .
- the rate tie  $\beta^T \leq c$  and its displayed sign gates  $0 \leq \beta, 0 \leq V_d(x) \mapsto \text{hc}, \text{h}\beta$ , and the nonneg row read at the start point ( $\text{hVdnonneg}$  with  $\text{hx/hDsub}$ ) — the  $V_d(x)$  gate is what lets the outer assembly pass from the  $\beta^T V_d(x)$  miss bound to the affine row's  $c V_d(x)$ ; fully rational at this profile; the catalogue's  $c = q^{-1}$  is one instance.
- the concluded  $\text{qraAffine}$  atom  $[(1, V_a), (c, V_d)]$  at threshold  $1 - p \mapsto$  the start condition  $\text{hthr} : \forall a \ x + c \cdot V_d \ x \leq 1 - p$ , verbatim affine row.
- side conditions and regularity as at the siblings ( $\text{hR3/hR4}$  at the composite stop set; the measurability pack undisplayed).

Width note: beyond the two safe-direction ties, neither side is wider — every displayed row lands on a named hypothesis, and the statement's flattening loses nothing the display promises (each inline family is exactly its slice's row family, stopped where the display stops it).

## Lean verifier receipts

module BernsteinLogicAux.QtslBattery; bound build 5c75f9923f27... (bound from receipt 3fd830b4914bdeda, 2026-08-04T01:56:58Z). A receipt records that named checking layers accepted a build: (module, compiled-artifact SHA-256, environment SHA-256, checker layers), minted when the checking gate ran; the store receipts attesting the bound build are listed with the layers each run credited. Nothing here asks the reader to trust the store: every layer is an independently runnable program over the quoted sources — rebuild the module and re-run the checkers to reproduce the verdict. Receipts attesting superseded builds credit no layer and are omitted from this rendering (the count of omissions, if any, is noted below).

| receipt          | minted               | layers             | status  |
|------------------|----------------------|--------------------|---------|
| 3fd830b4914bdeda | 2026-08-04T01:56:58Z | build+decorrelated | current |
| 96b18d8572451f65 | 2026-08-04T03:11:31Z | build+decorrelated | current |

13 further receipt(s) in the store attest superseded builds of this module and are omitted from this rendering.

module BernsteinLogicAux.LayerD.Until; bound build 5abcb1cb41f6... (bound from receipt dbbf5ae370de0748, 2026-08-04T01:57:07Z). #### gate-layer coverage of the bound build:

build (lake build (elaboration)) current

replay (leanchecker (official kernel replay)) stale only

hardened (safe\_verify (hardened screen)) stale only

decorrelated (lean4export + nanoda (decorrelated kernel)) current

comparator: none no fixture in the three-implementation comparator harness (compiled / kernel-interpreted / reference-interpreted) exercises this rule.

## HOL4 statement

### NO HOL STATEMENT YET

The HOL4 development ports the base calculus's checker chain (theory bern\_catalogue, developed side by side with the base catalogue sources, stopping below the proof-object layer); it contains no probability or measure theory. QUNTILBATTERY lives one theory-extension edge above the base calculus and its soundness content is path-space measure theory (a stopped-supermartingale slice, a discounted-supermartingale slice, and a union bound over a début decomposition), for which no counterpart exists anywhere in the ported development. A HOL statement of this rule would be a new measure-theoretic campaign, not an extension of the ported checker chain; until one exists, this box is the honest state of the edifice.

## HOL verifier receipts

### NONE

no HOL verification receipt exists for this rule.

## Proof

Genre: admissible rule (tier 2) — a proof-tree-rewriting recipe. The general admissible template (one node  $\rightarrow$  a derivation fragment over core and previously-justified rules, applied leaf-first) is stated in the NORM section, Recipe R16.1, and not restated here; this section gives the rule's instance. The verified theorems quoted above warrant the rule at the **discrete-kernel profile**; the profile remark at the end states what remains a hypothesis beyond it.

**Recipe R43.1** (the QUNTILBATTERY rewrite). A QUNTILBATTERY node carries: an avoid certificate  $V_a$  with its rows (drift off  $A \cup R$ , floor on  $A$  only, nonneg), a deadline certificate  $V_d$  with its rows (decay factor  $\beta$  off  $A \cup R$ , floor on all of the hull off the target, nonneg, bound), the shared side conditions (hull; fail-closed at the composite exit set  $A \cup R$ ), the sign gate  $\beta \geq 0$  with the rate tie  $\beta^T \leq c$ , and the threshold row  $V_a(x) + c V_d(x) \leq 1 - p$  on the concluded affine region. Here  $A$  over-approximates the falsity set of the safe-side formula  $\varphi_s$  and  $R$  under-approximates the truth set of the target  $\varphi$ . The node rewrites to a derivation fragment over three constituents:

$$\frac{V_a \text{ rows} \quad V_d \text{ rows} \quad \beta^T \leq c \quad V_a + c V_d \leq 1 - p \text{ on the region}}{\mathcal{M}, x_0 \in \{V_a + c V_d \leq 1 - p\} \models \text{SProbGE}(p, \text{PUntil}(T, \varphi_s, \varphi))} \sim \text{QUNTILBATTERY} \begin{array}{l} \text{(i) a QSafetyBattery slice: the battery pattern (QSAFETYBATTERY,} \\ \text{at the composite stop set } \textit{Stop} := (A \cup R) \cup D^c, \text{ certificate } V_a \\ \text{(ii) a QDeadlineBattery slice: the deadline miss bound (QDEADLINE} \\ \text{at target } A \cup R, \text{ certificate } V_d; \\ \text{(iii) one QUNIONBOUND node on the début decomposition (Ler} \end{array}$$

Honesty note, in the PCONSTEXACT tradition: the two slices are consumed through their *verified slice lemmas*, not by literal re-application of full battery nodes — the QSafetyBattery slice's floor family is deliberately weaker than a full safety node's (floor on the bad-exit set only; see [Remark R43.4](#)), and the QDeadlineBattery slice is consumed in complemented (miss-bound) form. The shipped verified object is therefore the assembled soundness lemma, whose Lean structure *is* this rewrite: it consumes the deadline theorem as a black box, applies the union bound once, and re-proves neither battery.

**Proposition R43.2** (semantic warrant, first-hit form). *On the substrate of the shared preamble, suppose: the  $V_a$  rows — drift off  $A \cup R$  within  $D$ , floor  $V_a \geq 1$  on  $A \cap \bar{D}$ , nonneg on  $\bar{D}$ ; the  $V_d$  rows — decay  $\int V_d dK y \leq \beta V_d(y)$  off  $A \cup R$  within  $D$ , floor  $V_d \geq 1$  on  $\bar{D} \setminus (A \cup R)$ , nonneg and bound  $M$  on  $\bar{D}$ ; hull and fail-closed side conditions at exit set  $A \cup R$ ;  $\beta \geq 0$  and the rate tie  $\beta^T \leq c$ . Then for every  $x \in D$  with  $V_a(x) + c V_d(x) \leq 1 - p$ ,*

$$\Pr_x[\exists n \leq T, \omega_n \in R \wedge \forall j < n, \omega_j \notin \text{Stop}] \geq p, \quad \text{Stop} = (A \cup R) \cup D^c.$$

*Proof.* Three bounds, then arithmetic. (i, the QSafetyBattery slice.) Clamp  $V_a$  as in the safety battery, with the floor forced only off  $D \cup R$  (the certificate is silent on the target away from  $A$ ). The stopped process at  $\text{Stop}$  is a nonnegative supermartingale,  $\geq 1$  whenever a first  $\text{Stop}$ -visit presents a bad state: a bad state lies in  $\text{Stop} \setminus R = (A \setminus R) \cup (D^c \setminus R)$ , and every reachable one is covered — in  $A \setminus R$  it lies in  $\bar{D}$  (a first visit is either the start, in  $D$ , or one kernel step from  $D \setminus \text{Stop}$ , confined to  $\bar{D}$  by the hull row), where the floor row on  $A \cap \bar{D}$  applies; in  $D^c \setminus R$ , which is the region off  $D \cup R$ , the forced clamp applies. Ville's inequality gives

$$E_1 := \{\text{some first Stop-visit is bad}\}, \quad \Pr_x[E_1] \leq V_a(x).$$

The floor is asked on  $A$  and off  $D \cup R$  only — in particular never on  $R \setminus A$ , which is what lets a landing there cost no  $V_a$ -budget (a landing in  $A \cap R$ , if the ties permit one, still succeeds, but the avoid floor prices it as avoid-territory; the no-charge-for-winning story is the  $R \setminus A$  story — [Remark R43.4](#)). (ii, the QDeadlineBattery slice.) The deadline battery's miss bound at target  $A \cup R$ , consumed as a black box and weakened from missing  $A \cup R$  to missing the larger  $\text{Stop}$  — avoiding  $\text{Stop} \supseteq A \cup R$  through  $T$  entails avoiding  $A \cup R$  through  $T$ , so  $E_2$  below is contained in the black box's miss event:

$$E_2 := \{\forall k \leq T, \omega_k \notin \text{Stop}\}, \quad \Pr_x[E_2] \leq \beta^T V_d(x) \leq c V_d(x),$$

the last step by the rate tie and  $V_d(x) \geq 0$ . (iii, the glue.) The d but decomposition (Lemma R42.3) at  $(\text{Stop}, R, T)$  says the complement of the concluded first-hit event is contained in  $E_1 \cup E_2$ ; one QUNIONBOUND application in real-valued form (Prop. R42.2, its nonnegativity riders supplied by the nonneg rows and by  $c \geq \beta^T \geq 0$ ) gives  $\Pr_x[\text{fail}] \leq V_a(x) + c V_d(x) \leq 1 - p$ . Complement — licit because the first-hit event is a region event over measurable regions (the profile's regularity pack), so its measure and its complement's sum to one; the weakening to possibly-nonmeasurable satisfaction events happens only in the next proposition, in the monotone direction.  $\square$

**Proposition R43.3** (soundness of QUNTILBATTERY). *With the two formula ties —  $A$  over-approximating where  $\varphi_s$  fails,  $R$  under-approximating where  $\varphi$  holds — the first-hit event weakens to the truth of the bounded-until formula along the path: for  $x$  in the affine region,  $\Pr_x[\exists n \leq T, \text{sat}(\omega_n) \wedge \forall j < n, \text{sat}_s(\omega_j)] \geq p$  — the concluded judgment  $\mathcal{M}$ ,  $x_0 \in \{V_a + c V_d \leq 1 - p\} \models \text{SProbGE}(p, \text{PUntil}(T, \varphi_s, \varphi))$ , its region the sublevel set  $\{V_a + c V_d \leq 1 - p\}$ .*

*Proof.* On the first-hit event: the landing state is in  $R$ , hence satisfies  $\varphi$ ; every earlier state avoided  $\text{Stop} \supseteq A$ , hence satisfies  $\varphi_s$  by the contrapositive of the safe-side tie. Monotonicity of the (outer) measure; neither satisfaction predicate is required measurable.  $\square$

**Remark R43.4** (two floors doing different work).  $V_a$ 's floor is on  $A$  only: the avoid certificate is silent on  $R \setminus A$ , so a landing there costs no certificate budget — the rule does not charge for winning (a state of  $A \cap R$ , when the ties permit one, is a successful landing that the avoid floor nonetheless prices as avoid-territory; the free wins are exactly the  $R \setminus A$  ones). Demand the floor on all of  $R$  too and the concluded region shrinks pointlessly: every reachable success state would need  $V_a \geq 1$ , pushing  $V_a(x) + c V_d(x)$  past any useful threshold.  $V_d$ 's floor is on all of  $\bar{D}$  off the target, exactly as its parent deadline battery requires — weaken it and [Remark R41.6](#)'s counterexample (the frozen chain certified to arrive) imports after one padding: take  $A = \emptyset$  and  $V_a \equiv 0$  (all avoid rows trivially satisfied), and the until node is its deadline slice, frozen chain and all. The asymmetry is not an optimization; it is the two slices' different jobs made visible in their price lists.

**Remark R43.5** (fail-closed, and the rate tie).  $D^c$  joins the stop set on the *bad* side: leaving the modelled domain before reaching the target counts as failure, while an  $R$ -landing succeeds wherever it lands (the target tie is global). Drop the rate tie  $\beta^T \leq c$  and step (ii)'s budget transfer fails — the affine atom would under-budget the *certified* miss bound by the gap  $(\beta^T - c) V_d(x)$  (the actual miss mass sits somewhere below the bound; it is the transfer, not the mass, that the tie protects). The catalogued instance  $c = q^{-1}$  with  $0 < q \leq e^{\theta T}$ ,  $\beta = e^{-\theta}$  satisfies the tie, and at this profile the whole certificate is exact rational arithmetic — no transcendental leaf anywhere; one becomes available through the deadline battery's Taylor-leaf pattern (Prop. R41.5) when  $\theta$ -rates are wanted.

**Remark R43.6** (tier, argued). Admissible, not alias: three premise sub-derivations (two battery slices and a union bound), not a respelling of one. And deliberately not monolithic core: a third self-contained soundness lemma would duplicate two batteries' arguments line by line — the assembled proof instead consumes the deadline theorem as a black box and the union bound as one application, which is this catalogue's admissibility discipline enforced at the Lean level. The concluded region is the affine atom with rows  $[(1, V_a), (c, V_d)]$  and threshold  $1 - p$  — the region-vocabulary generalization whose  $k = 1$  case is the ordinary sublevel atom.

**Remark R43.7** (profile — what is proven, at which presentations). Proven: the discrete-kernel profile, sorry-free (sound\_QUntilBattery\_firstHit, sound\_QUntilBattery), with both slice lemmas and the union bound as named constituents. Also proven: the continuous-time profile

at the martingale-problem presentation (`sound_GSHS_until_mp`, `sound_GSHS_until_battery_mp`, `module QtslAux.LayerD.MPDDischarge` of the semantic-universe strand's auxiliary package) — the recipe above is profile-independent in *shape*, and both parents' formerly filed constituents (the safety slice's stopping theory, the deadline slice's discounted supermartingale) are supplied by the same martingale-problem discharge that serves the parents, composite stop set included. The martingale-problem theorems are hash-bound by this catalogue's binder via the `qtsl-aux` package registration, family-wide, so the dashboard row carries no conditional mark — each named profile is proven, and its theorems are bound.

## Rule 44. QSTREETTBATTERY (core rule)

### The rule (Steele metanotation)

as realized in the mechanized development; source row: QTSL-rules.toml — QStreettBattery. The metanotation statement is typeset by hand for notational quality; its mechanized ground truth is the Lean statement below, extracted from the sources at every build of this book and hash-bound. The rule *roster* is machine-checked (every mechanized rule tag round-trips to exactly one catalogue row); the statement *text* is editorial, checked by eye against the extracted Lean beside it.

$$\begin{array}{c}
 V_0, (W_i)_{i \leq k}, (V_i)_{i \in A} : \text{QCertFam}; \quad A \subseteq \{1, \dots, k\} \text{ (the pairs posting absorbing certificates); } \quad \varepsilon_0 \in \mathbb{Q}_{>0}; \quad (\gamma_i)_{i \in A} \in \mathbb{Q}_{>0} \\

 \mathcal{M}, x_0 \in \{V_0 \leq y\} \vdash \text{SProbGE}(p, \text{PDwellStreett}(\text{PairBase}(\rho_1, \varphi_1), \dots, \text{PairBase}(\rho_k, \varphi_k)))
 \end{array}$$

a region written left of the turnstile scopes the row ( $R \vdash P$ :  $P$  at every point of  $R$ ); the certificate families enter as certificate data — shared references with no claim content; the rows impose every claim.  $J_i$  is *defined, not supplied*: the mixed soundness theorem defines it from the posted absorbing data, with the  $J_i := \emptyset$  case (absorbing family omitted,  $i \notin A$ ) the conservative scope — the baked node carries no absorbing-family fields yet, so this optional face is not yet wire-representable (a named schema divergence).  $V_0$ 's own nonnegativity rides the QSAFETYBATTERY kit row, stated once there. The margin premise  $\gamma_i > 0$  together with the absorbing floor forces  $J_i \cap \llbracket \rho_i \rrbracket = \emptyset$ ; no disjointness row is asked. The target-cell containment  $W_i \equiv 0$  is recomputed by the checker. The threshold tie  $p + y \leq 1$  is the soundness theorem's own hypothesis, displayed as a side condition: the baked Streett node carries no tie proof field yet (contrast the deadline and until nodes) — a named schema divergence, not a checked leaf. The conclusion is the region-conditioned judgment in constructor vocabulary, as at QSAFETYBATTERY; the base-exact request consumption is the PairBase constructor.

QSTREETTBATTERY concludes a probabilistic Streett-acceptance judgment: with probability at least  $p$ , a path of the modelled system satisfies every pair of the Streett condition  $\text{PDwellStreett}(\text{PairBase}(\rho_1, \varphi_1), \dots, \text{PairBase}(\rho_k, \varphi_k))$  (surface syntax  $\text{Streett}((\rho_1, \varphi_1), \dots, (\rho_k, \varphi_k))$ ) — for each pair  $i$ , if *request* states (those satisfying  $\rho_i$ ) occur infinitely often along the path, then *response* states (those satisfying  $\varphi_i$ ) also occur infinitely often. This is the shape of liveness-under-fairness obligations, and it subsumes recurrence and stability claims as degenerate pairs (the sub-rule sections that follow this one). A producer discharges such a specification by synthesizing the certificate family  $(V_0; (V_i, \gamma_i, W_i)_{i \leq k}; \varepsilon_0)$ : one safety certificate  $V_0$  confining probability mass to the operating region, and, per pair, a ranking certificate  $W_i$  that pays out a fixed rational  $\varepsilon_0 > 0$  at every un-responded request — plus, optionally, absorbing certificates  $(V_i, \gamma_i)$  licensing the sharper ranking scope discussed in the proof. Every premise row is an inherited base-calculus sequent (a Bernstein-cone-family polynomial inequality the base kernel replays), so the bundle adds *zero* kernel arithmetic: its entire content is the supermartingale assembly one judgment level up, which is where its soundness lemma lives.

What the checker recomputes rather than trusts: the target-cell containment behind the  $W_i \equiv 0$  convention (the collapse side-condition of the QSTREETTTARGETCELLCOLLAPSE section), and — when the absorbing face becomes wire-representable — the carved-out set  $J_i := \{V_i \leq 1 - \gamma_i\} \cap (I \setminus \llbracket \rho_i \rrbracket)$ ,  $I$  the display's confinement region  $\{V_0 < 1\}$ :  $J_i$  is *defined*, never supplied by the producer, but today it is defined by the soundness theorem from posted theorem data — the baked node carries no absorbing-family fields, so no enacted recomputation exists yet. Also recomputed: the region-hull mass side-conditions that make the certificate scopes fail-closed. The threshold tie  $p + y \leq 1$  is displayed as a side condition, not a checked leaf: it is the soundness theorem's own hypothesis, and the baked Streett node carries no tie proof field yet (contrast the deadline and until nodes) — a named schema divergence, as the rule's flavor text states. What would break without the hypotheses: the nonnegativity rows for all three certificate families are load-bearing (a signed certificate can subsidize probability-mass leakage — the recorded two-branch counterexample at the quantitative-safety rule); the strictness  $\varepsilon_0 > 0$  is load-bearing ( $W \equiv 1$  satisfies every row at  $\varepsilon_0 = 0$  while no response is ever forced); the floor and hull rows pair up fail-closed. Each is remarked, with its counterexample, in the proof.

Scope, stated plainly: the statements bound and receipt-credited in this edition are the five excursion-cluster theorems quoted below — the analytic engine of the typeset proof — together with the end-to-end assembly `sound_QStreettBattery` (the conservative-scope bundle theorem over `Kernel.traj`) and its discharged carved-scope corollary `sound_QStreettBattery_carved_discharged` (absorbing certificates supplied as kernel-level rows, composed through the absorption discharge), both in the auxiliary module `BernsteinLogicAux.QStreett`. These cover the rule at the *discrete-kernel profile* (a time-homogeneous Markov chain presented by a single step kernel); the complement-request tie `sound_QStreettBattery_tie` is likewise bound in this edition, under the `QSTREETTCMPLREQUEST` entry that carries its event-level kernel; the parameterized `sound_QStreettBattery_carved` and the absorption discharge `absorptionBound_of_kernel` remain machine-checked and cited, not bound. The continuous-time transport that used to sit beyond that — the residue this rule shared with its safety and deadline siblings, and this entry's former conditional mark — is discharged and bound: at the martingale-problem profile the whole bundle is proven, confinement and

zero-decrement ranking rows (`sound_GSHS_streett_bundle_mp`) together with the strict-decrement rows from strict presentations (`sound_GSHS_streett_bundle_mp_strict`, whose ranking-row input is produced by `rankingSegmentDynkin_of_mp_strict` from the pathwise progress row of `MPFlowStrict`), leaving no analytic per-model hypothesis in the bundle. All four are hash-bound below via the registered `qtsl-aux` package, so the dashboard row carries no conditional mark: each named profile is proven, and its theorems are bound.

notes Two design notes travel with the rule. First, schema: the bundle rule's rows are baked in the extension theory (per-pair rank certificates and nonneg proof lists); the source catalogue's old MISSING-ROW finding is discharged. Second, why Streett is the *primitive* acceptance condition here: a Büchi condition is exactly a one-pair Streett condition with the trivially-true request, and the degenerate-pair specialization erases the resulting tautological rows — so a Streett-primitive compile pays no premium on Büchi-shaped workloads, while a Büchi-primitive compile would pay an exponential-in- $k$  automaton re-encoding on Streett-shaped ones. The sub-rules of the following sections (degenerate request, complement request, target-cell collapse) are the compile-level faces of this design.

## Lean statement

BernsteinLogicAux.Excursions.**Supermartingale.exists\_ae\_tendsto\_of\_nonneg**

statement bound

```
/-- **Almost-everywhere convergence of nonnegative supermartingales** (K5a): a
nonnegative supermartingale is automatically bounded in  $L^1$  (its expectation is
nonincreasing), so Doob's convergence theorem applies with no further hypothesis. Dual
of MeasureTheory.Submartingale.exists_ae_tendsto_of_bdd` via Supermartingale.neg`. -/
theorem Supermartingale.exists_ae_tendsto_of_nonneg [IsFiniteMeasure  $\mu$ ] {f :  $\mathbb{N} \rightarrow \Omega \rightarrow \mathbb{R}$ }
  (hf : Supermartingale f  $\mathcal{G}$   $\mu$ ) (hnonneg :  $0 \leq f$ ) :

  ∀m ω ∂μ, (∃f n in atTop, X n ω ∈ R) → ∃f n in atTop, X n ω ∈ G

```

BernsteinLogicAux.QStreett.sound\_QStreettBattery

statement bound

```

/-- **`sound_QStreettBattery`, discrete profile** (catalogue T9, rev 3
`thm:bundle-sound` transported; the assembly the receipt ledger carried as
FILED). Hypotheses: the `V₀` battery rows – quantitative safety of the
confinement region `D \ U` (the catalogue's `I := {V₀ < 1}` is the instance
`U := {y | 1 ≤ V₀ y}`, whose floor row is tautological) – and, per pair
`i : ι` (countable; a Streett bundle's finite `k` is an instance), the ranking
rows for `Wᵢ` at the **conservative scope** of the design note §4.1's ranking
row ("conservative on `I \ [φᵢ]`"): nonincrease off the response region,
`εᵢ`-decrease at requests, on the confinement region. Conclusion:
`Pr[(∏ᵢ (Fin(Rqᵢ) ∪ Inf(Gᵢ))) ≥ p]` from the start region `D n {V₀ ≤ thr}` with
`p + thr ≤ 1` – the compile's atom `{V₀ ≤ 1 - p}` is `thr = 1 - p`.

```

The absorbing certificates `(Vᵢ, γᵢ)` of the full bundle datum do not appear: at the conservative ranking scope they are not consumed (they license only the `Jᵢ` carve-out – see `sound\_QStreettBattery\_carved`). Presentation–semantics bridge and GSHS residue: module docstring. -/

QtslAux.LayerD.MPDischarge . **MPFlowStrict**

statement bound

```

/-- **The strict martingale-problem presentation of a segment.** An
`MPFlow` together with the pathwise progress row: along every path, the
accumulated generator drift of the discounted certificate reaches `≤ -ε`
by some finite sample time. For exit paths the natural witness is the exit
time itself (`stopClip` caps the accumulation there), so the row reads
`∫0∞ T ω mpDrift ≤ -ε`; the intended certificate-side derivation is a
strict drift bound `≤ -δ` on the segment together with a minimum dwell
time `t_min`, giving `ε = δ · t_min`. -/
structure MPFlowStrict (M : SegmentModel State) (θ : ℝ) (V : State → ℝ)
  (x : State) (ε : ℝ) extends MPFlow M 0 V x where

## Correspondence (Steele display ↔ Lean)

**reviewer-certified against the displayed texts** The dictionary below is a reviewer-certified statement of how the mechanized statements above interpret the displayed rule: display metavariable  $\mapsto$  Lean binder, each display hypothesis  $\mapsto$  the premise or side condition carrying it, the display conclusion  $\mapsto$  the goal — with any deliberate difference in width between display and mechanization named outright. Certification is recorded as a hash triple over (the displayed cell, the extracted statement texts, this dictionary's own text); if any of the three changes, this block turns amber until a reviewer re-certifies. The correspondence claim itself remains editorial — reviewer-grade, not machine-checked; its machine-checked successor types each soundness statement against the rule as a structured object, and supersedes this block per rule as it lands.

The displayed judgment is concluded by `sound_QStreettBattery` (second block): from the  $V_0$  battery rows on the confinement region and, per pair, the conservative-scope ranking rows (nonincrease off the response region,  $\varepsilon_i$ -decay at requests), it concludes  $\Pr[\bigcap_i (\text{Fin}(Rq_i) \cup \text{Inf}(G_i))] \geq p$  from the start region at  $p + \text{thr} \leq 1$  — the display's conclusion at the discrete-kernel profile over `kernel.traj`; `_carved_discharged` adds the carved scope with the absorbing certificates consumed as kernel-level rows. (Notation:  $\text{Fin}(A) / \text{Inf}(A)$  denote the path events that a trajectory visits  $A$  finitely / infinitely often — the acceptance atoms of the Hanoi Omega-Automata format [11] and of Emerson-Lei conditions [68]; equivalently  $\text{Inf}(A) = \{\rho \mid \text{Inf}(\rho) \cap A \neq \emptyset\}$  in the infinity-set convention,  $\text{Inf}(\rho)$  being the set of states visited infinitely often. The upright  $\text{Fin}$  is distinct from the sans-serif type former  $\text{Fin}$  of the mechanization.) The five bound excursion theorems are the K5 analytic engine the assembly consumes, stated over an arbitrary filtered probability space  $(\Omega, \mathcal{G}, \mu)$  with an adapted state process  $X$  — *wider* than the discrete-kernel chain. What the display's rows reach in the engine's bound set, per pair:

- ranking interior rows  $\mathcal{A}_m W_{i,m} \leq -\varepsilon_0$  off  $\llbracket \varphi_i \rrbracket \cup J_i \mapsto$  the conditional-shadow pair in `streett_ae_frequently_response`: `hdrift` (conditional non-increase off the response set  $G$ ) and `hdriftR` (decay by  $\varepsilon_0$  at requests off  $G$ ) — per-time a.e. conditional-expectation clauses, the probabilistic sibling of the integrated semantic-shadow forms on the deterministic pages; the `BernCone` rows reach them through the kernel bridge in the unbound assembly. Conclusion:  $\forall^\mu \omega, (\exists^\mu n, X n \in \omega \in R) \rightarrow \exists^\mu n, X n \in \omega \in G$  — the probabilistic content of one Streett pair, exactly.
- `nonneg` rows  $\mapsto$  `hnonneg : 0 ≤ V` — and the roster's two-branch signed-certificate counterexample is why the binder is there.
- $\varepsilon_0 \in \mathbb{Q}_{>0} \mapsto$  `hε : 0 < ε0` (real, the  $\mathbb{Q}$  cast upstream); the quantitative window/hitting forms (`streett_window_sum_le`, `ranking_hitting_sum_le`) take the nonstrict  $0 \leq \varepsilon_0$  — strictness is consumed exactly where Borel-Cantelli or summability-to-hitting needs it (`ae_hits_of_ranking`, the frequently-response theorem).
- the measurability pack `hmR/hmG` (request/response events adapted at each time) is undisplayed regularity — the probabilistic sibling of the `PsdCert` evaluability class, as on the battery pages.
- `Supermartingale.exists_ae_tendsto_of_nonneg (K5a)` is engine stock: Doob convergence with the  $L^1$  bound derived from nonnegativity, no display row corresponds.

Width note: the  $V_0$  safety kit, the  $W_i \leq C_i$  upper-bound rows, the threshold tie  $p + y \leq 1$ , and the carved  $J_i$  with the absorbing families  $(V_i, \gamma_i)$  as kernel-level rows are all consumed by the two bound assembly statements; the  $G_5$  target-cell containment binds in the `QSTREETTTARGETCELLCOLLAPSE` entry, and the complement-request tie remains cited, not bound. The martingale-problem profile, stated at its true extent: the confinement half and all zero-decrement ranking rows are discharged by `sound_GSHS_streett_bundle_mp`, and the strict-decrement rows ( $\varepsilon_i > 0$ ) by strict presentations — `MPFlowStrict` extends `MPFlow` by one pathwise progress row (along every path the accumulated generator drift of the discounted certificate reaches  $-\varepsilon$  by a finite sample time; the certificate-side derivation is  $\varepsilon = \delta \cdot t_{\min}$  from a strict segment drift bound and a minimum dwell time), consumed by `rankingSegmentDynkin_of_mp_strict`, which needs presentations only at requested-but-ungranted states — so `sound_GSHS_streett_bundle_mp_strict` leaves no analytic per-model hypothesis in the bundle; all four hash-bound below. The honest scope note that replaces the retired residue sentence: the strict route's progress row is *pathwise* (per-path accumulation, not in-expectation), the per-state bound  $\varepsilon \leq V(x)$  is derived by the theorem rather than assumed as a row, and the strict theorem is a companion to the mixed-profile `_mp` form, not an in-place replacement — the landed  $\varepsilon = 0$  signature survives for citation stability. Width note, deliberate strengthening stated: the displayed ranking row asks strict  $-\varepsilon_0$  decay everywhere off  $\llbracket \varphi_i \rrbracket \cup J_i$ , where

the bound statements need nonincrease off the response and strict decrease only at requests — the displayed single-row form is stronger than consumed, safe direction, and the producer emits it as one family.

## Lean verifier receipts

module BernsteinLogicAux.Excursions; bound build ad62a846f92e... (hashed from the built olean at bind time). A receipt records that named checking layers accepted a build: (module, compiled-artifact SHA-256, environment SHA-256, checker layers), minted when the checking gate ran; the store receipts attesting the bound build are listed with the layers each run credited. Nothing here asks the reader to trust the store: every layer is an independently runnable program over the quoted sources — rebuild the module and re-run the checkers to reproduce the verdict. Receipts attesting superseded builds credit no layer and are omitted from this rendering (the count of omissions, if any, is noted below).

**gate-layer coverage of the bound build:**build (lake build (elaboration)) currentreplay (leanchecker (official kernel replay)) currenthardened (safe\_verify (hardened screen)) currentdecorrelated (lean4export + nanoda (decorrelated kernel)) current

comparator: none no fixture in the three-implementation comparator harness (compiled / kernel-interpreted / reference-interpreted) exercises this rule.

**HOL4 statement****NO HOL STATEMENT YET**

Absent, with the gap located precisely: the HOL4 development ports the *base-calculus* checker cone (the `bern_catalogue` theory, built side-by-side with the Lean catalogue module) — its object is the wire-format certificate checker of the sequent stratum. The extension theory's satisfaction stratum has no HOL artefact at all, so there is no HOL-side wire object a checker could consume today. A HOL statement becomes meaningful once the extension stratum is ported; it would then join the proof-object layer the HOL port's own coordination notes name as successor territory. (Checked against the HOL sources: no Streett-, satisfaction-, or NNF-shaped definitions exist there.)

**HOL verifier receipts****NONE**

no HOL verification receipt exists for this rule.

**Proof**

Genre: core rule (tier 1) — an ordinary mathematical proof at Putnam-exam-solution detail, at the rule's *proven scope*: discrete-kernel profile, conservative ranking scope ([Remark R44.7](#) states the scope loudly, including what is and is not hash-bound in this edition). Every hypothesis is used and remarked on; the anchor table maps steps to the Lean declarations that carry them.

**Setting and claim.** The semantic object at the discrete-kernel profile is a time-homogeneous Markov chain on a measurable state space  $S$ , presented by a single step kernel  $K$  (modes, guards, and resets of the underlying hybrid presentation flattened into  $K$ ), with path measure  $\mu_x$  on  $S^{\mathbb{N}}$  from a start state  $x$  (the Ionescu–Tulcea trajectory construction). Region data: the operating region  $D$ , its checker-recomputed hull  $\bar{D} \supseteq D$ , and the exit set  $U$  for the confinement certificate; per Streett pair  $i$  (finitely or countably many), a certified request region  $R_i$  and response region  $G_i$ . Certificate data: the confinement certificate  $V_0 : S \rightarrow \mathbb{R}$  with threshold  $y$ , and per pair a ranking certificate  $W_i : S \rightarrow \mathbb{R}$  with decay rate  $\varepsilon_i \in \mathbb{Q}_{>0}$  and bound  $C_i$ . The premise rows, each an inherited base-calculus sequent:

- (H1) threshold arithmetic:  $p + y \leq 1$  (exact rational).
- (H2) hull and mass rows, for every  $z \in D \setminus U$ :  $K(z)(\bar{D}) = 1$  and  $K(z)(D \cup U) = 1$  — one-step mass stays in the hull, and stays in operating-or-exit.
- (H3) confinement rows: one-step generator row  $\int V_0 dK(z) \leq V_0(z)$  on  $D \setminus U$  (with one-step integrability); floor  $V_0 \geq 1$  on  $U \cap \bar{D}$ ; nonnegativity  $V_0 \geq 0$  on  $\bar{D}$ .
- (H4) ranking rows, per pair, on the confinement region  $D \setminus U$ : bounds  $0 \leq W_i \leq C_i$  on  $\bar{D}$ ; nonincrease  $\int W_i dK(z) \leq W_i(z)$  off the response region  $G_i$ ; request decay  $\int W_i dK(z) \leq W_i(z) - \varepsilon_i$  on  $R_i \setminus G_i$ .
- (H5) initialization:  $x \in D$  and  $V_0(x) \leq y$  — i.e.  $x$  lies in the concluded region atom `qraSublevel`( $V_0, y$ ).

The claim: under (H1)–(H5),

$$\mu_x \left\{ \omega \mid \forall i, (\exists^\infty n, \omega_n \in R_i) \Rightarrow (\exists^\infty n, \omega_n \in G_i) \right\} \geq p,$$

which is the Streett-acceptance reading of the concluded judgment  $\mathcal{M}, x_0 \in \{V_0 \leq y\} \models \text{SProbGE}(p, \text{PDwellStreett}(\text{PairBase}(\rho_1, \varphi_1), \dots, \text{PairBase}(\rho_n, \varphi_n)))$  once the certified regions are tied to the formulas ([Remark R44.8](#)).

**Lemma R44.1** (confinement).  $\mu_x \{ \omega \mid \forall n, \omega_n \in D \setminus U \} \geq 1 - V_0(x) \geq 1 - y \geq p$ .

*Proof.* This is the quantitative-safety rule consumed whole: by (H2)–(H3),  $V_0$  read along the path and stopped at the first  $U$ -visit is a nonnegative supermartingale with barrier  $\geq 1$  on the stopped set, so Ville’s maximal inequality bounds the exit probability by  $V_0(x)$ ; the mass rows (H2) keep every reachable state inside  $\bar{D}$ , where the nonnegativity and floor rows actually hold — the fail-closed pairing. The full argument, with the two-branch counterexample showing the nonnegativity row is not decoration, is the QSAFETYBATTERY section’s; the displayed intermediate bound is the chain inside that argument — Proposition R40.4 applied to the clamped certificate of Lemma R40.5 bounds the exit probability by  $g(x) = V_0(x)$  — consumed here through the same end-to-end statement (anchor table), whose packaged form Theorem R40.6 then states as the  $\geq p$  complement. The last two inequalities are (H5) and (H1).  $\square$

**Lemma R44.2** (windowed telescoping invariant). *Fix one pair  $(R, G)$  with certificate  $W$ , rate  $\varepsilon$ , and suppose the generator rows hold globally:  $\mathbb{E}[W_{n+1} \mid \mathcal{F}_n] \leq W_n$  a.e. off  $G$ , and  $\leq W_n - \varepsilon$  a.e. on requests off  $G$ , for the process  $W_n := W(X_n)$  adapted to a filtration  $(\mathcal{F}_n)$ , with  $W_n \geq 0$  and integrable. For a window start  $N$  let  $A_{N,n} := \{\text{no response in } [N, n)\}$ . Then for all  $n \geq N$ ,*

$$\int_{A_{N,n}} W_n d\mu + \varepsilon \sum_{k=N}^{n-1} \mu(A_{N,k+1} \cap \{X_k \in R\}) \leq \int W_N d\mu.$$

*Proof.* Induction on  $n$  from  $n = N$ , where  $A_{N,N}$  is everything and the sum is empty. For the step:  $A_{N,n+1}$  is  $\mathcal{F}_n$ -measurable (it constrains coordinates  $< n+1$ ), so the tower property converts  $\int_{A_{N,n+1}} W_{n+1}$  into  $\int_{A_{N,n+1}} \mathbb{E}[W_{n+1} \mid \mathcal{F}_n]$ . Split  $A_{N,n+1}$  at time  $n$  into its request and non-request parts: on the request part the decay row pays  $\varepsilon \cdot \mu(A_{N,n+1} \cap \{X_n \in R\})$  — exactly the new summand — and on the non-request part the nonincrease row holds (both parts lie off  $G$  at time  $n$ , since  $A_{N,n+1}$  forbids a response at  $n$ ). Finally  $A_{N,n+1} \subseteq A_{N,n}$  and  $W_n \geq 0$  shrink the integral domain monotonically, closing the induction. Two features deserve remark. First, *no sign condition on  $\varepsilon$  is used here*: the decrement paid at step  $k$  is exactly the summand recorded at index  $k$ , an exact cancellation — positivity of  $\varepsilon$  enters only in Lemma R44.3. Second, the two generator rows do genuinely different work and neither subsumes the other: nonincrease carries the (possibly long) non-request stretches; decay is charged only at requests.  $\square$

**Lemma R44.3** (summability and Borel–Cantelli). *Under the hypotheses of Lemma R44.2 with  $\varepsilon > 0$  and  $W$  bounded: almost surely, infinitely many requests imply infinitely many responses.*

*Proof.* Fix a window start  $N$ . Lemma R44.2 bounds every partial sum of the series below by  $\mathbb{E}[W_N]$  uniformly (the leading integral it retains is nonnegative), and a nonnegative series is the supremum of its partial sums, so

$$\varepsilon \sum_{j \geq 0} \mu(\{\text{no response in } [N, N+j]\} \cap \{X_{N+j} \in R\}) \leq \mathbb{E}[W_N] < \infty,$$

so the un-responded-request events of window  $N$  are summable, and by the Borel–Cantelli lemma their limsup is null. A path with infinitely many requests but only finitely many responses has a finite (possibly empty) set of response times; for any window start  $N$  beyond all of them ( $N = 0$  when there are none), the path lies in infinitely many of window  $N$ ’s un-responded-request events — i.e. in that null limsup. The union over the countably many window starts is null, which is the claim. (Here  $\varepsilon > 0$  is finally consumed, dividing the bound; boundedness of  $W$  supplies the finite right-hand side and, upstream, integrability of every  $W_n$ .)  $\square$

**Lemma R44.4** (localization to the confinement region). *The bundle’s ranking rows (H4) hold only on  $D \setminus U$ , while Lemma R44.2 wants global rows. Define the localized pair process: flag the state with the survival indicator of the event “no visit to  $U \cup D^c$  so far”, zero the certificate at the first exit, and count exited states as responded. Then the flagged process satisfies the global hypotheses of Lemmas R44.2–R44.3, and the conclusion, restricted to paths confined forever, descends to the raw process: almost surely on  $\{\forall n, \omega_n \in D \setminus U\}$ , infinitely many  $R_i$ -visits imply infinitely many  $G_i$ -visits.*

*Proof.* Write it out. Let  $\sigma := \inf\{n : \omega_n \in U \cup D^c\}$  (a stopping time — the regions are measurable), and localize by

$$W'_n := W(\omega_n) \mathbf{1}[\sigma > n], \quad G' \text{ holds at time } n : \iff \omega_n \in G \text{ or } \sigma \leq n,$$

the zeroed certificate and the enlarged (exited-counts-as-responded) response. Check the global hypotheses of Lemma R44.2 for  $(W', G')$  by cases on the state class at time  $n$ :

(*surviving, non-request*)  $\sigma > n$  and  $\omega_n \notin R$ : off  $G'$  means also  $\omega_n \notin G$ , so  $\omega_n \in (D \setminus U) \setminus G$ ; the mass row (H2) carries the next step into  $\bar{D}$ , where  $0 \leq W \leq C$  (H4), so  $W'_{n+1} = W(\omega_{n+1}) \mathbf{1}[\sigma > n+1] \leq W(\omega_{n+1})$  almost surely on this branch — the masked certificate is dominated by the unmasked one — and  $\mathbb{E}[W'_{n+1} \mid \mathcal{F}_n] \leq \int W dK(\omega_n) \leq W(\omega_n) = W'_n$  by the nonincrease row.

(*surviving, request*) the same domination, closed by the decay row:  $\mathbb{E}[W'_{n+1} \mid \mathcal{F}_n] \leq W'_n - \varepsilon$ .

(*exited*)  $\sigma \leq n$ : the state is in the enlarged response  $G'$  by construction, so no generator row is demanded of it — the global hypotheses hold vacuously, and indeed  $W'_n = 0$  there.

Bounds and adaptedness:  $0 \leq W'_n \leq C$  everywhere (H4 on  $\bar{D}$  while surviving — reachable surviving states lie in  $\bar{D}$  by (H2) and the deterministic start — zero after), and  $W'$  is adapted since  $\sigma$  is a stopping time. (To consume Lemma R44.2 literally in its certificate reading, run the chain on the flagged state space  $S \times \{0, 1\}$ : the flag is a running conjunction updated by membership of each new coordinate in  $U \cup D^c$ , so the flagged chain is again time-homogeneous Markov,  $W'$  and the enlarged response are state functions there —  $W'(z, f) = f \cdot W(z)$ , response  $\iff f = 0$  or  $z \in G$  — and the flagged trajectory law projects to  $\mu_x$ .) Lemmas R44.2–R44.3 then give: almost surely, infinitely many requests-while-surviving imply infinitely many  $G'$ -responses. Restricted to confined paths the flag never trips ( $\sigma = \infty$ ),  $W' = W$ , the enlarged response set coincides with  $G_i$ , and the conclusion is the raw one. The exited-counts-as-responded device is not a weakening of the claim: the theorem below asserts the pair implications only on the confinement event of Lemma R44.1, exactly where the device is invisible.  $\square$

**Theorem R44.5** (soundness of QSTRETTBATTERY, discrete profile, conservative ranking scope). *Under (H1)–(H5),  $\mu_x\{\omega \mid \forall i, (\exists^\infty n, \omega_n \in R_i) \Rightarrow (\exists^\infty n, \omega_n \in G_i)\} \geq p$ .*

*Proof.* Per pair  $i$ , Lemmas R44.2–R44.4 give the pair implication almost surely on the confinement event. The pairs are countably many, so the almost-sure statements intersect (countable intersection of co-null sets); the Streett event therefore contains the confinement event up to a null set, and Lemma R44.1 bounds its measure below by  $p$ .  $\square$

*Remark R44.6* (every hypothesis earns its seat). (H1): at  $p + y > 1$  the concluded atom admits start states with  $1 - V_0(x) < p$  and Lemma R44.1 yields less than  $p$  — the sublevel atom and the probability bound are coupled by exactly this row. (H2): drop the hull row and probability mass can reach  $U \setminus \bar{D}$ , where no floor row holds, voiding Ville’s barrier in Lemma R44.1; drop the operating-or-exit row and the stopped-process reading of the confinement certificate is unsound (mass escapes the region where a generator row was ever asserted) — the two recomputed side-conditions are the fail-closed pairing. (H3) *nonnegativity*: load-bearing, not hygiene — a signed confinement certificate can go negative on one branch and thereby subsidize exit mass on another; the recorded two-branch counterexample lives in the QSAFETYBATTERY section. (H4) *strictness*: at  $\varepsilon_i = 0$ , take  $W_i \equiv 1$  on a one-state chain with  $K(s) = \delta_s$ ,  $R_i = \{s\}$ ,  $G_i = \emptyset$ ,  $V_0 \equiv 0$ : every row holds, the path requests forever, and no response ever occurs — the conclusion fails at any  $p > 0$ . (H4) *bound rows*: the constant  $C_i$  gives integrability of the localized certificate (Lemma R44.4) and the finite right-hand side of Lemma R44.3; nonnegativity of  $W_i$  additionally powers the monotone domain-shrink step inside Lemma R44.2. (H5): initialization is what makes the region atom an *under*-approximation of the satisfaction set — the workhorse orientation of the satisfaction judgment.

*Remark R44.7* (scope, loudly). Three ledger entries: the discrete-profile warrant, the cited testimony, and the continuous-time profile. (i) *Bound in this edition*: the five excursion-cluster declarations (anchor table) — the windowed telescoping engine (Lemmas R44.2–R44.3), its additive-drift sibling for plain reachability (the ranking hitting-time bound and almost-sure hitting), and the nonnegative-supermartingale convergence theorem (part of the cluster, available for the general excursion picture; the presented proof path does not consume it) — together with the end-to-end assembly at the conservative scope (sound\_QStreettBattery — Lemmas R44.1, R44.4 and Theorem R44.5 as one statement) and the discharged carved-scope corollary (sound\_QStreettBattery\_carved\_discharged), both in the auxiliary module BernsteinLogicAux.QStreett. These warrant the rule at the discrete-kernel profile. Also bound in this edition, under the QSTRETTCMPLREQUEST entry whose section carries its event-level kernel: the formula tie (sound\_QStreettBattery\_tie, with streett\_event\_mono). (ii) *Machine-checked and cited, not bound*: the localization lemma under its own name (streett\_pair\_localized), and the parameterized route to the sharper carved ranking scope, where decay is demanded only off  $G_i \cup J_i$  with  $J_i := \{V_i \leq 1 - \gamma_i\} \cap (I \setminus \llbracket \rho_i \rrbracket)$  —  $I$  is the display’s confinement region  $\{V_0 < 1\}$ ; this section’s exit set instances it as  $U = \{1 \leq V_0\}$  — and the absorbing certificates  $(V_i, \gamma_i)$  repay the carve-out: a Lévy upward-convergence argument shows frequent  $J_i$ -visits preclude frequent requests, the absorption bound being discharged from kernel-level rows by a time-shifted supermartingale bridge plus a conditional Ville inequality (sound\_QStreettBattery\_carved, absorptionBound\_of\_kernel). Binding those in a later edition is the named follow-up; until then this page claims them as testimony, not as hash-bound warrant. (iii) *The martingale-problem profile, discharged whole*: the confinement half and every zero-decrement ranking row ( $\varepsilon_i = 0$ : nonincrease off the response region) are discharged by sound\_GSHS\_streett\_bundle\_mp, and the strict-decrement rows ( $\varepsilon_i > 0$ ) by strict presentations — MPFlowStrict extends the martingale-problem presentation by one pathwise progress row (along every path the accumulated generator drift of the discounted certificate reaches  $-\varepsilon$  by a finite sample time; the intended certificate-side derivation is  $\varepsilon = \delta \cdot t_{\min}$  from a strict segment drift bound and a minimum dwell time), and rankingSegmentDynkin\_of\_mp\_strict derives from it the ranking row family the  $\varepsilon = 0$  route could not produce, needing presentations only at requested-but-ungranted states. The proof mechanism, for the record, is *not* the lower-bound optional-sampling inequality an earlier edition of this remark predicted: the stopped certificate splits as martingale plus drift accumulation, the existing upper-bound optional sampling serves the martingale part, and dominated convergence on  $\varepsilon$ -truncated drift accumulations supplies the strict term (the lower-bound lemma was built anyway, completing the optional-sampling module). The assembled sound\_GSHS\_streett\_bundle\_mp\_strict therefore carries no analytic per-model hypothesis — all four statements live in module QtsLAux.LayerD.MPDIscharge and are hash-bound in this edition via the registered qtsl-aux package, so, like its safety and deadline siblings, this rule carries no conditional mark: each named profile is proven, and its theorems are bound.

*Remark R44.8* (the formula tie). The theorem is stated over certified regions  $R_i, G_i$ ; the concluded judgment speaks of formulas  $\rho_i, \varphi_i$ . The sound directions are asymmetric: certified *request* regions may *over*-approximate the request denotation, certified *response* regions must *under*-approximate the response denotation — weakening the hypothesis and strengthening the conclusion of each pair implication. This is the content of the complement-request sub-rule (QSTRETTCMPLREQUEST, two sections on), whose event-level kernel is two monotonicity steps.

*Remark R44.9* (degenerate pairs, and why Streett is primitive). A Büchi acceptance condition is the one-pair Streett condition with trivially-true request; on that pair the bundle degenerates to the classical recurrence certificate (the QSTRETTDEGENERATE section). The converse embedding does not exist at parity of cost: deterministic Büchi automata recognize only limit languages [150], and re-encoding a  $k$ -pair Streett condition Büchi-primitively costs an exponential-in- $k$  automaton product, where the bundle pays  $2k + 1$  certificates. Streett conditions enter the literature as the complemented-pairs acceptance of [226], the linear-time face of Rabin’s pairs [205]; the standard survey is [232].

*Remark R44.10* (relation to the literature). The ranking row is a Foster–Lyapunov drift condition [81, 180] in certificate form; its use to force almost-sure hitting is the ranking-supermartingale argument of the probabilistic-programs tradition [41]. The confinement certificate is Ville’s inequality [234]; the convergence item of the bound cluster is Doob’s supermartingale convergence theorem [64]; the summability-to-limsup step is Borel–Cantelli (see e.g. [65, Thm. 2.3.1]). As with the polynomial rules of the base calculus, the certificate form moves all analytic content into the *choice* of  $(V_0, W_i, \varepsilon_0)$ : what the checker replays is row

arithmetic, and what this proof adds is only the assembly. No completeness is claimed or needed here; the source catalogue records a completeness theorem for the bundle relative to its termination seam, outside this book’s kernel-facing scope.

## Rule 45. QAVGBATTERY (core rule)

### The rule (Steele metanotation)

as realized in the mechanized development; source row: `QTSL-rules.toml` — *QAvgBattery*. The metanotation statement is typeset by hand for notational quality; this rule cites no Lean statements yet (the absence is stated loudly below). The rule *roster* is machine-checked (every mechanized rule tag round-trips to exactly one catalogue row); the statement *text* is editorial.

$$\frac{\text{drift}_m : R_m \vdash g - r_m - \mathcal{A}_m B_m \geq 0 \quad \overline{\text{guard}_j} \quad \overline{\text{floor}_m} \quad \overline{\text{nonneg}_{g_m}} \quad \text{tie} : \vdash g \bowtie c}{\mathcal{M}, x_0 \in R \models \text{SReturn} \bowtie (c, \text{poAvg}(o))}$$

**QAVGBATTERY** concludes long-run-average claims from the certificate pair of the Poisson equation: a rational *gain*  $g$  and a *bias* certificate family  $B$ , with the drift rows carrying the constant term inside each row's sequent polynomial — so the discharge species is the same sign-sequent genre as every other battery, with no new checker architecture. On the upper face the drifts certify gain minus reward minus generator-of-bias nonnegative on scope, and the tie bounds the gain above the claimed constant; on the lower face the orientations flip, and the floors bound the bias above so the correction term dies in the limit. The walk recomputes the required orientation from the concluded root — a producer never declares a face.

**notes** Entered at the roster census: the node was baked — including its tie proof field, which the safety and acceptance batteries still lack — but had never been catalogued. No Lean statement binds it yet; the display is the schema-faithful schematic form, and the soundness obligation (the Poisson-pair argument: telescoping the bias along the trajectory, dividing by the horizon, the floors killing the correction term) is stated in the proof section as an obligation, not discharged.

### Theory rows (geolog)

The rule's certificate content as it is declared in the geolog theory the checker loads — payload schema, side-condition demands, and axiom rows, quoted from the theory source at every build of this catalogue (a stale quotation cannot exist). Axiom modes: *chase* = the engine derives; *report* = a violation is a loud judgment; *refuse* = a violation gates admission. Side-condition relations are discharged by bounded evaluation at the engine's ground seam, never by derivation.

### Lean statement

**not yet mechanized** this rule cites no Lean statements: nothing on this page is hash-bound for it, and its dashboard row shows the same absence across the statement, receipt, and correspondence columns.

### HOL4 statement

#### NO HOL STATEMENT YET

No HOL development of the extension theory exists.

### HOL verifier receipts

#### NONE

no HOL verification receipt exists for this rule.

## Proof

Genre: core rule (tier 1), battery group. This section states the rule's soundness obligation exactly, per the catalogue's completeness-over-polish charter (a rule that can only be named-and-gapped is still a row); the discharge is open debt on the mechanization column, and the schema quoted in the entry is the baked ground truth.

**Soundness obligation.** The Poisson-equation pair argument: with drift rows certifying  $g - r_m - \mathcal{A}_m B_m \geq 0$  on scope per mode (upper face), guards at the seams, floors and nonnegativity on the bias family, telescoping the compensated bias along any admitted trajectory bounds the accumulated reward's time average by the gain plus a correction term of order bias-over-horizon; the floors kill the correction in the limit, and the tie transfers the gain bound to the claimed constant. The lower face is the same argument with orientations flipped. The obligation is stated over the same behavioural models as the safety battery's, with the walk recomputing the required orientation from the concluded root.

*Remark* R45.1 (status). No Lean statement binds this node. The discharge species is the landed sign-sequent genre — the expected mechanization reuses the battery kit's supermartingale machinery with the compensated bias in the certificate slot — and the node's tie field is already baked, so no schema motion is expected at mechanization time.

## Rule 46. QRATEFROMCLOCK (core rule)

### The rule (Steele metanotation)

as realized in the mechanized development; source row: QTSL-rules.toml — *QRateFromClock*. The metanotation statement is typeset by hand for notational quality; this rule cites no Lean statements yet (the absence is stated loudly below). The rule *roster* is machine-checked (every mechanized rule tag round-trips to exactly one catalogue row); the statement *text* is editorial.

$$\frac{\text{TrMeter}(t, d) \quad \rho \cdot d \geq 1 \quad \sigma \geq 1 \quad \text{qtsl\_rate\_clock}(n)}{\mathcal{M} \models \text{SRateLE}(\{t\}, \rho, \sigma)}$$

QRATEFROMCLOCK discharges the rate-envelope specification former from clock data alone: a transition whose clock carries a dwell floor  $d$  (demonic, forced, or carved — never the instantaneous race clock, which has no floor) satisfies  $\text{SRateLE}(\{t\}, \rho, \sigma)$  for any  $\rho \cdot d \geq 1$  and  $\sigma \geq 1$ . The rate lane's other feed is the supermartingale kit — a different evidence family, deliberately not conflated; this rule is the clock seam.

The premise is a premise *class*, not a node:  $\text{TrMeter}(t, d)$  names three things together — the transition's clock-content conformance (exactly-one content presentation, wing positivity; already checker-discharged rows), a POSITIVE lower witness  $0 < d \leq d'$  below the declared floor  $d'$  (positivity is the class's own formation: a nonpositive witness would inhabit the class while its division law is vacuous), and the meter law as a *named obligation* — the conformance rows alone do not prove elapsed-time separation. The law: under the declared meter semantics (dwell accrues per transition; guard exit and own firing reset it), successive firings of  $t$  are separated by at least  $d$  of elapsed time, hence  $N_t(T) \leq T/d + 1$  on any window under every resolution. The checker's trusted contribution is two exact rational inequalities ( $\rho \cdot d \geq 1$ ;  $\sigma \geq 1$ ) over conformance rows it already checks — with  $d$  resolved deterministically as the transition's declared finite floor (no producer freedom; the class is monotone in  $d$ , so the declared floor is the tightest lawful witness).

The concluded envelope is an upper-prevision claim; the obligation actually proved is pathwise and surely — strictly stronger — and the entry records that strength so a future pathwise rate former can strengthen the conclusion without touching the node. Singleton rosters compose by the rate lane's documented disjoint-roster sum law (envelopes add on disjoint rosters); this rule is that law's first in-catalogue consumer.

**notes** The schema is baked in the extension theory: the node, its walk, the race-refusal, and the per-wing meter-demand rows are quoted below from the theory source; the per-transition conformance rows the premise class reads were checker-discharged before the node landed. What remains owed is the meter law's first formalization (the shared keystone of this rule family's continuous-time obligations — the discrete-profile induction is elementary). No Lean statement binds the node yet; the mechanization column is honest open debt.

### Theory rows (geolog)

The rule's certificate content as it is declared in the geolog theory the checker loads — payload schema, side-condition demands, and axiom rows, quoted from the theory source at every build of this catalogue (a stale quotation cannot exist). Axiom modes: chase = the engine derives; report = a violation is a loud judgment; refuse = a violation gates admission. Side-condition relations are discharged by bounded evaluation at the engine's ground seam, never by derivation.

The baked rows: the node with its two exact-rational envelope reports, the race-refusal (the instantaneous wing carries no floor and is refused as subject), the walk, and the per-wing meter-demand rows that mint the premise class's conformance-plus-floor reading at the declared dwell floor.

## Lean statement

not yet mechanized

this rule cites no Lean statements: nothing on this page is hash-bound for it, and its dashboard row shows the same absence across the statement, receipt, and correspondence columns.

## HOL4 statement

### NO HOL STATEMENT YET

No HOL development of the extension theory exists; this node's content is walk structure over baked rows.

## HOL verifier receipts

### NONE

no HOL verification receipt exists for this rule.

## Proof

Genre: core rule (tier 1), the timers family (the rate-envelope former's clock seam). This section states the rule's soundness obligation exactly; the rule's schema and walk are baked in the extension theory (rows quoted in this section), and the meter law's formalization is the named obligation of the mechanization column.

**Soundness obligation (meter law + pathwise domination).** Under the declared meter semantics (dwell accrues per transition; guard exit and own firing reset it), a transition  $t$  whose clock carries floor  $d > 0$  fires with successive firings separated by at least  $d$  of elapsed time, hence  $N_t(T) \leq T/d + 1$  on any window of length  $T$ , under every resolution. The witness  $d$  is the transition's declared finite floor, resolved deterministically by the walk (the premise class demands a POSITIVE witness at most the declared floor, and is monotone, so the declared floor is the tightest lawful instance; no producer freedom enters). With the checker-verified exact inequalities  $\rho \cdot d \geq 1$  and  $\sigma \geq 1$ ,  $N_t(T) \leq T/d + 1 \leq \rho T + \sigma$  pathwise and surely; the upper prevision of the roster firing count therefore satisfies the envelope — pathwise domination, strictly stronger than the concluded prevision-level claim. The instantaneous race clock is refused as subject: it carries no floor, and its rate story is a different evidence family (the thinning majorant), deliberately not conflated with this seam.

*Remark R46.1 (status).* The schema is baked: the node, its walk, the race-refusal, and the per-wing meter-demand rows are landed theory rows (quoted in this section), and the premise class's per-transition conformance rows were checker-discharged before the node landed. No Lean statement binds the node yet; the meter LAW is the named obligation — elementary at the discrete profile, and the shared keystone of this rule family's continuous-time lifts.

## Rule 47. QINVRELATIVIZE (core rule)

### The rule (Steele metanotation)

as realized in the mechanized development; source row: QTSL-rules.toml — *QInvRelativize*. The metanotation statement is typeset by hand for notational quality; its mechanized ground truth is the Lean statement below, extracted from the sources at every build of this book and hash-bound. The rule *roster* is machine-checked (every mechanized rule tag round-trips to exactly one catalogue row); the statement *text* is editorial, checked by eye against the extracted Lean beside it.

$$\frac{\text{BoxInv}(B, \nu, x)}{\text{AService}(B, T, \chi \cap \nu, x) \leftrightarrow \text{AService}(B, T, \chi, x)}$$

$B$  an *arbitrary* behaviour — no closure field consumed;  $\text{AService}$  is the début-as-infimum reading unpacked without infima (a visit at some  $t < T + \varepsilon$  for every  $\varepsilon > 0$ ),  $\text{BoxInv}$  the  $\square$  reading (every point of every solution from  $x$ ).

certificate content out of scope of the current baked theory — realized in Lean over the behavioural floor.

One of the three timed-core basis schemata proved non-admissible in the gñand completeness development (machine independence witnesses; see the proof section’s anchors), entering as tier-1 core: its soundness obligation is semantic, discharged at Putnam-exam-solution detail in the proof section and mechanized in `BernsteinLogic.QtslTimedCore`. Sound over *all* behavioural models — no side condition; the proof consumes none of the closure laws.

### Lean statement

`BernsteinLogic.QtslTimedCore.sound_QInvRelativize`

statement bound

```
/-- **QInvRelativize** (obligation relativization through invariants), the
biconditional core: under  $\square \nu$ , the visit sets of  $\chi \cap \nu$  and  $\chi$ 
coincide along every solution from  $x$ , so the two service claims
agree. Sound for ARBITRARY behaviors — none of B1–B3 is consumed.
Catalogue: tier-1 core; independence machine-checked — a 3-state
deadline-blind structure validates the remaining basis and every rule
while refuting this schema, so it is underivable. -/
theorem sound_QInvRelativize (B : Behavior X) (T : ℝ≥0) (ν χ : Set X) (x : X)
  (hbox : B.BoxInv ν x) :
    B.AService T (χ ∩ ν) x ↔ B.AService T χ x
```

### Correspondence (Steele display ↔ Lean)

#### NO CORRESPONDENCE DICTIONARY YET

## HOL verifier receipts

documentary hol-strict CLEAN: theory bern\_tr\_t5qdyn, 22 theorems, 0 cheat-tagged, 0 nonstandard axioms (whitelist: DISK\_THM; the four bool axioms) — verification run of 2026-07-22 on an isolated build host, against a content-addressed checkout of the exact sources cited here (git blob d64e1954...); an independent acceptance host ran the same build green at the porting seating (2026-07-21). The timed core this statement quantifies over is ported with an inventoried seam: trajectories ride the full real line with  $0 \leq t$  guards at exactly the positions where the nonnegative-time binders sit, and the behaviour structure's closure proof fields flatten to an explicit wellformedness conjunction. This rule's twin is closure-free exactly as its Lean statement is — stated over a bare forward-solution set, strictly stronger than a hypothesis-for-hypothesis transliteration.

HOL receipts are documentary: quoted results of hol-strict runs and census rows from the HOL4 development's build evidence, not minted receipt artefacts. A HOL receipt store (the Lean store's twin) is named future work.

## Proof

Genre: core rule (tier 1) — an ordinary mathematical proof at Putnam-exam-solution detail. This section also fixes the semantic setting shared by the three timed-core sections (QINVRELATIVIZE, QFIRSTSERVICE, QFIRSTSERVICEPLIT); the later two abbreviate it as “the timed-core setting”.

**Setting (shared by the timed-core sections).** A *behavioural model* is a state set  $X$  with atom denotations  $\llbracket \cdot \rrbracket \subseteq X$ , extended over  $\neg, \wedge, \vee$  as set operations (so  $\llbracket \chi \wedge \nu \rrbracket = \llbracket \chi \rrbracket \cap \llbracket \nu \rrbracket$ , etc.), and, for each  $x \in X$ , a set  $B_x$  of trajectories  $\tau : \mathbb{R}_{\geq 0} \rightarrow X$ , subject to three closure conditions and nothing else: **(B1)**  $\tau \in B_x \Rightarrow \tau(0) = x$ ; **(B2)**  $\tau \in B_x \Rightarrow (s \mapsto \tau(t+s)) \in B_{\tau(t)}$ ; **(B3)**  $\tau \in B_x$  and  $\tau' \in B_{\tau(t)}$  imply  $\tau \cdot_t \tau' \in B_x$ , where  $\tau \cdot_t \tau'$  follows  $\tau$  on  $[0, t)$  and  $\tau'$  (re-anchored) from  $t$  on. Empty  $B_x$  is permitted. The *début* of  $\tau$  into  $E \subseteq X$  is  $\tau_E := \inf\{t : \tau(t) \in E\}$  ( $\inf \emptyset = \infty$ ); worst-case service and invariance are

$$x \models A_T \varphi \iff \forall \tau \in B_x : \tau_{\llbracket \varphi \rrbracket} \leq T, \quad x \models \Box \varphi \iff \forall \tau \in B_x \forall t : \tau(t) \in \llbracket \varphi \rrbracket,$$

where deadlines  $T$  range over *finite* nonnegative reals (the mechanization types them so); in particular  $\tau_E \leq T$  forces the visit set nonempty. For  $S \subseteq \mathbb{R}_{\geq 0}$  and finite  $T \geq 0$ ,  $\inf S \leq T$  holds iff for every  $\varepsilon > 0$  some  $s \in S$  has  $s < T + \varepsilon$  — the infimum-free reading used throughout, and the form the mechanized statements take. A début need *not* be attained: nothing in B1–B3 forces a visit set to contain its infimum. The three sections split exactly along that line: QINVRELATIVIZE is sound over all behavioural models; the two first-service laws demand *attained débuts* for their obligation formulas (their sections state the attainment lemma and the countermodel making the demand honest).

**Claim (sound\_QInvRelativize).**  $\Box \nu \wedge A_T(\chi \wedge \nu) \leftrightarrow \Box \nu \wedge A_T \chi$  is valid in every behavioural model.

**Theorem R47.1** (soundness of QINVRELATIVIZE). *At every state  $x$  of every behavioural model:  $x \models \Box \nu \wedge A_T(\chi \wedge \nu)$  iff  $x \models \Box \nu \wedge A_T \chi$ .*

*Proof.* It suffices to show, for  $x \models \Box \nu$ , that  $x \models A_T(\chi \wedge \nu) \iff x \models A_T \chi$ ; conjoining  $\Box \nu$  on both sides then gives the displayed biconditional (both sides carry it as a conjunct).

Let  $\tau \in B_x$ . By  $\Box \nu$ , every point of  $\tau$  lies in  $\llbracket \nu \rrbracket$ , so

$$\{t : \tau(t) \in \llbracket \chi \wedge \nu \rrbracket\} = \{t : \tau(t) \in \llbracket \chi \rrbracket\} \cap \{t : \tau(t) \in \llbracket \nu \rrbracket\} = \{t : \tau(t) \in \llbracket \chi \rrbracket\},$$

the second equality because the second intersecting set is all of  $\mathbb{R}_{\geq 0}$ . Equal visit sets have equal infima:  $\tau_{\llbracket \chi \wedge \nu \rrbracket} = \tau_{\llbracket \chi \rrbracket}$ . So the two service conditions agree trajectory by trajectory, hence at  $x$ .  $\square$

*Remark R47.2* (why the invariant conjunct is everything). Drop  $\Box \nu$  and the right-to-left direction fails in a two-location clocked model whose  $\chi$ -location lies outside  $\nu$ : the service fact about  $\chi$  says nothing about  $\chi \wedge \nu$ . (Left-to-right needs no invariant — every  $\chi \wedge \nu$ -visit is a  $\chi$ -visit, so that direction is valid outright.) The proof uses  $\Box \nu$  once, exactly to collapse the two visit sets.

*Remark R47.3* (no closure is consumed). The proof never builds a trajectory: B1–B3 are not used, so the schema is sound over arbitrary trajectory assignments. Its independence witness must therefore deviate in the *operator* rather than the trajectory space, and does: the independence witness is a machine-checked, deadline-blind three-state structure whose service-operator interpretation deviates at an unreachable state; it validates the seed basis — the axiom set prior to the corrections these sections record — while refuting QINVRELATIVIZE directly. Nothing else in the basis ties finite worst-case débuts to reachability, which is precisely what this axiom asserts.

| proof step                    | formal anchor                                                                                                          |

## Rule 48. QFIRSTSERVICE (core rule)

### The rule (Steele metanotation)

as realized in the mechanized development; source row: QTSL-rules.toml — *QFirstService*. The metanotation statement is typeset by hand for notational quality; its mechanized ground truth is the Lean statement below, extracted from the sources at every build of this book and hash-bound. The rule *roster* is machine-checked (every mechanized rule tag round-trips to exactly one catalogue row); the statement *text* is editorial, checked by eye against the extracted Lean beside it.

$$\frac{B.\text{FusionClosed} \quad 0 < n \quad \forall i. \text{FirstVisits}(B, \alpha_i) \quad \forall i. \text{AService}(B, T_i, \alpha_i, x)}{\text{AService}(B, \min_i T_i, \text{fsTarget}(\alpha, T), x)}$$

$\text{fsTarget}(\alpha, T) = \bigcup_i (\alpha_i \cap \{y \mid \forall j \neq i. \text{AService}(B, T_j, \alpha_j, y)\})$  — some obligation served *right here* while every other still binds at its ORIGINAL budget; FirstVisits = nonempty visit sets have least elements (attained débuts).

certificate content out of scope of the current baked theory — realized in Lean over fusion-closed behaviours with attained débuts.

One of the three timed-core basis schemata proved non-admissible in the gmand completeness development (machine independence witnesses; see the proof section's anchors), entering as tier-1 core: its soundness obligation is semantic, discharged at Putnam-exam-solution detail in the proof section and mechanized in BernsteinLogic.QtslTimedCore. Sound over behavioural models with *attained débuts* for the obligation formulas — a real side condition: the proof section's closing remark carries the countermodel (mechanized) witnessing failure without it.

### Lean statement

BernsteinLogic.QtslTimedCore . sound\_QFirstService

statement bound

```
/-- **FS_n (first-service, EQ-FS)** – mechanized soundness. Over a
fusion-closed behavior with attained débuts for the obligations: if
every obligation binds at `x`, then within the tightest budget every
solution reaches a state where some obligation is served and every
other still binds at its ORIGINAL budget. Catalogue: tier-1 core
(schema family, n ≥ 2; the n = 1 instance is degenerate-derivable);
independence machine-checked – a blind 3-state structure validates the
FS-less basis over all definable sets while refuting a 2-obligation
instance of FS. Class boundary:
`qFirstService_attainment_necessary` below. -/
theorem sound_QFirstService (hB3 : B.FusionClosed) (hn : 0 < n)
  (α : Fin n → Set X) (T : Fin n → ℝ≥0) (x : X)
  (hatt : ∀ i, B.FirstVisits (α i))
  (hx : ∀ i, B.AService (T i) (α i) x) :
  B.AService (Finset.univ.inf' (Finset.univ_nonempty_iff.mpr {(0, hn)})) T)
  (B.fsTarget α T) x
```

BernsteinLogic.QtslTimedCore . qFirstService\_attainment\_necessary

statement bound

```
/-- **The theorem the master doc's countermodel E certifies** : there is
a fusion-closed behavior and a state satisfying the FS2 premise at
budgets (2, 2) whose FS-target conclusion FAILS – so the attainment
hypothesis of `sound_QFirstService` is not removable, and FS_n is
invalid over raw C0. Witness trajectory for the failure: `stay 0`;
along it every point of the FS-target would be a spine point at some
parameter in (1, 2) at which the OTHER atom still binds – but from a
rational point the escape `esc t t` never meets `Eb`, and from an
irrational point it never meets `Ea`. -/
theorem qFirstService_attainment_necessary :
  ∃ (S : Type) (B : Behavior S) (α : Fin 2 → Set S) (x : S),
  B.FusionClosed ∧
  (∀ i, B.AService 2 (α i) x) ∧
  ¬ B.AService 2 (B.fsTarget α (fun _ => 2)) x
```

**HOL verifier receipts**

documentary hol-strict CLEAN: theory bern\_tr\_t5qdyn, 22 theorems, 0 cheat-tagged, 0 nonstandard axioms (whitelist: DISK\_THM; the four bool axioms) — verification run of 2026-07-22 on an isolated build host, against a content-addressed checkout of the exact sources cited here (git blob d64e1954...); an independent acceptance host ran the same build green at the porting seating (2026-07-21). The timed core this statement quantifies over is ported with an inventoried seam: trajectories ride the full real line with  $0 \leq t$  guards at exactly the positions where the nonnegative-time binders sit, and the behaviour structure's closure proof fields flatten to an explicit wellformedness conjunction; the fusion-closure hypothesis is consumed exactly as displayed. The début/attainment engine lemmas behind the statement (first-visit and served-point existence) are ported alongside as local instruments, mirroring their private status on the Lean side.

HOL receipts are documentary: quoted results of hol-strict runs and census rows from the HOL4 development's build evidence, not minted receipt artefacts. A HOL receipt store (the Lean store's twin) is named future work.

**Proof**

Genre: core rule (tier 1), in the timed-core setting fixed at the QINVRELATIVIZE section. This section proves the attainment lemma shared by the timed-core sections; the class boundary (attained débuts are a genuine side condition) is certified by an explicit countermodel, sketched in the final remark and mechanized alongside the soundness lemma.

**Claim (sound\_QFirstService).** For  $n \geq 2$  obligations,

$$\bigwedge_{i \leq n} A_{T_i} \alpha_i \sqsubseteq A_{\min_i T_i} \left( \underbrace{\bigvee_i (\alpha_i \wedge \bigwedge_{i' \neq i} A_{T_{i'}} \alpha_{i'})}_{=: \Phi, \text{ the FS-target}} \right)$$

is valid in every behavioural model with *attained débuts* for the  $\alpha_i$ : along every trajectory, a nonempty  $\alpha_i$ -visit set has a least element.

**Lemma R48.1** (attainment). *Attained débuts hold: (i) for closed  $\llbracket \alpha_i \rrbracket$  in any model whose trajectories are right-continuous into a topological state space; (ii) in every clocked model, for every formula; (iii) in discrete time, for every formula.*

*Proof.* (i) Let  $E$  be closed,  $\tau$  right-continuous,  $V := \{t : \tau(t) \in E\}$  nonempty,  $t_0 := \inf V$ . If  $t_0 \notin V$ , pick visits  $v_n \downarrow t_0$  with  $v_n > t_0$ ; right-continuity at  $t_0$  gives  $\tau(v_n) \rightarrow \tau(t_0)$ , and since each  $\tau(v_n) \in E$ , every neighbourhood of  $\tau(t_0)$  meets  $E$ , so  $\tau(t_0) \in \overline{E} = E$  — contradiction. (No Hausdorff hypothesis: only “closed” and “converges” are used.) (ii) A clocked trajectory is a right-continuous step function through finitely many locations on any bounded window, with the post-jump location taken at the jump time, and every formula denotation is a union of locations — a subset of the finite discrete location set, hence closed; so (i) applies with the discrete topology. Concretely: given any visit at time  $R$ , the visit set restricted to  $[0, R]$  is a finite union of left-closed intervals, whose least point is the global least point. (iii) Nonempty subsets of  $\mathbb{N}$  have least elements.  $\square$

**Theorem R48.2** (soundness of QFIRSTSERVICE). *In every behavioural model with attained débuts for  $\alpha_1, \dots, \alpha_n$ , at every state  $x$ : if  $x \models A_{T_i} \alpha_i$  for all  $i$ , then  $x \models A_{\min_i T_i} \Phi$ .*

*Proof.* Let  $\tau \in B_x$ .

*First services exist.* For each  $i$ ,  $\tau_{\llbracket \alpha_i \rrbracket} \leq T_i < \infty$  forces the visit set nonempty; attainment gives its least element  $t_i = \tau_{\llbracket \alpha_i \rrbracket} \leq T_i$ .

*The first service overall.* Put  $t^* := \min_i t_i$ , attained at some  $i_0$ , and  $y := \tau(t^*) \in \llbracket \alpha_{i_0} \rrbracket$ . Choosing  $j^* \in \arg \min_i T_i$ :  $t^* \leq t_{j^*} \leq T_{j^*} = \min_i T_i$ .

*Co-obligations persist at  $y$ , at original budgets.* Fix  $i' \neq i_0$ ,  $\sigma \in B_y$ , and  $\varepsilon > 0$ . The fusion  $\rho := \tau \cdot t^* \sigma$  lies in  $B_x$  by B3 (typed by B1:  $\sigma(0) = y = \tau(t^*)$ ), so  $\rho_{\llbracket \alpha_{i'} \rrbracket} \leq T_{i'}$ , giving a  $\rho$ -visit of  $\alpha_{i'}$  at some  $s < T_{i'} + \varepsilon$ . If  $s < t^*$  then  $\rho(s) = \tau(s)$ , so  $t_{i'} \leq s < t^* \leq t_{i'}$  — impossible. Hence  $s \geq t^*$  and  $\rho(s) = \sigma(s - t^*)$ : a  $\sigma$ -visit at time  $s - t^* \leq s < T_{i'} + \varepsilon$ . As  $\varepsilon$  was arbitrary,  $\sigma_{\llbracket \alpha_{i'} \rrbracket} \leq T_{i'}$ . (Indeed  $\leq T_{i'} - t^*$ ; the schema states the weaker original-budget bound, which is what survives grid transport — the residual-split law QFIRSTSERVICE SPLIT is where the true residual is recovered.)

*Assembly.*  $\sigma$  was arbitrary, so  $y \models A_{T_{i'}} \alpha_{i'}$  for every  $i' \neq i_0$ ; with  $y \in \llbracket \alpha_{i_0} \rrbracket$ ,  $y \in \llbracket \Phi \rrbracket$ , and  $\tau$  visits it at  $t^* \leq \min_i T_i$ .  $\square$

**Remark R48.3** (each hypothesis, remarked). B1 types the fusion; B3 is the engine (facts about all of  $B_y$  reach back to the premise at  $x$  only through fusion); B2 is not consumed. Attainment is consumed exactly once, and essentially — to produce the service point  $y = \tau(t^*)$ : an infimum is not a visit. (The placement of  $s$  then runs on the ordinary lower-bound property of  $t_{i'}$ .) It is not removable: see the next remark. At  $n = 1$  the instance degenerates and is derivable; the schema family starts at  $n = 2$ .

**Remark R48.4** (the class boundary is real). Over bare B1–B3 models the schema is *false*. Countermodel (mechanized as `qFirstService_attainment_necessary`): a spine  $\{y_p : p \geq 0\}$  with  $\llbracket a \rrbracket$  the rational  $p \in (1, 2)$  and  $\llbracket b \rrbracket$  the irrational ones; from every  $y_p$ , the trajectories are the spine-ride and, for each  $s \geq p$  with  $s > 1$ , a ride-to- $s$ -then-exit to an atom-free sink. The family is fusion-closed; every trajectory from  $y_0$  meets both atoms before time 2 (density), so the premise  $A_2 a \wedge A_2 b$  holds; but at every  $y_q \in \llbracket a \rrbracket$  (so  $q \in (1, 2)$ , making the immediate exit legal) that exit kills  $A_2 b$ , at every  $y_i \in \llbracket b \rrbracket$  it kills  $A_2 a$ , and states outside the two atoms fail both disjuncts outright, so the FS-target denotes  $\emptyset$  and the conclusion fails. Dense interleaving of disjoint atoms along one trajectory is exactly what right-continuity into closed denotations forbids (Lemma R48.1(i)) — the countermodel lives strictly outside the attained class, as it must.

## Rule 49. QFIRSTSERVICE SPLIT (core rule)

### The rule (Steele metanotation)

as realized in the mechanized development; source row: QTSL-rules.toml — *QFirstServiceSplit*. The metanotation statement is typeset by hand for notational quality; its mechanized ground truth is the Lean statement below, extracted from the sources at every build of this book and hash-bound. The rule *roster* is machine-checked (every mechanized rule tag round-trips to exactly one catalogue row); the statement *text* is editorial, checked by eye against the extracted Lean beside it.

$$\frac{B.\text{FusionClosed} \quad 0 < n \quad \forall i. c < T_i \quad \forall i. \text{FirstVisits}(B, \alpha_i) \quad \forall i. \text{AService}(B, T_i, \alpha_i, x)}{\text{AService}(B, c, \text{fsTarget}(\alpha, T) \cup \text{residualCell}(\alpha, T, c), x)}$$

$\text{residualCell}(\alpha, T, c) = \{y \mid \forall i. \text{AService}(B, T_i - c, \alpha_i, y)\}$  — the no-service-by- $c$  branch pins elapsed time by the cutoff, recovering TRUE residuals  $T_i - c$  where  $\text{FS}_n$  can only re-issue original budgets.

certificate content out of scope of the current baked theory — realized in Lean over fusion-closed behaviours with attained débuts.

One of the three timed-core basis schemata proved non-admissible in the gmand completeness development — for this law the machine independence witnesses cover integer and half-integer deadline menus, with finer denominators open (see the proof section's closing remark and anchors) — entering as tier-1 core: its soundness obligation is semantic, discharged at Putnam-exam-solution detail in the proof section and mechanized in *BernsteinLogic.QtslTimedCore*. Sound over behavioural models with *attained débuts* for the obligation formulas — a real side condition; its witnessing countermodel is prose-only (not yet mechanized; the *QFirstService* countermodel is the mechanized one).

### Lean statement

BernsteinLogic.QtslTimedCore . sound\_QFirstServiceSplit

statement bound

```
/-- **FS-R (residual-split first-service)** – mechanized soundness,
same class as FS_n. For any cutoff `c` strictly below every budget:
within `c`, every solution reaches EITHER a first-service state
(original co-budgets – the FS-target) OR the residual cell, where
every obligation holds at its true residual `T i - c`. Genuinely new
on top of FS_n; independence machine-checked – a minimal 6-state
witness settles every all-integer deadline menu, and two further
certified 6-state witnesses extend the underivability to all
half-integer menus. -/

## HOL verifier receipts

documentary hol-strict CLEAN: theory bern\_tr\_t5qdyn, 22 theorems, 0 cheat-tagged, 0 nonstandard axioms (whitelist: DISK\_THM; the four bool axioms) — verification run of 2026-07-22 on an isolated build host, against a content-addressed checkout of the exact sources cited here (git blob d64e1954...); an independent acceptance host ran the same build green at the porting seating (2026-07-21). The timed core this statement quantifies over is ported with an inventoried seam: trajectories ride the full real line with  $0 \leq t$  guards at exactly the positions where the nonnegative-time binders sit, and the behaviour structure's closure proof fields flatten to an explicit wellformedness conjunction. The residual budget's truncated subtraction is rendered as the max-0 coercion — agreeing with the nonnegative-reals reading on the whole consulted domain, not only under the split theorem's guard.

HOL receipts are documentary: quoted results of hol-strict runs and census rows from the HOL4 development's build evidence, not minted receipt artefacts. A HOL receipt store (the Lean store's twin) is named future work.

## Proof

Genre: core rule (tier 1), in the timed-core setting fixed at the QINVRELATIVIZE section, with the attainment lemma of the QFIRSTSERVICE section. This is the fourth and final basis correction from the gnand completeness analysis: the law that makes the decision procedure's deadline-tightening step derivable.

**Claim (sound\_QFirstServiceSplit).** For  $n \geq 1$  obligations and any cutoff  $0 < c < \min_i T_i$ ,

$$\bigwedge_{i \leq n} A_{T_i} \alpha_i \sqsubseteq A_c \left( \Phi \vee \underbrace{\bigwedge_i A_{T_i - c} \alpha_i}_{=: P, \text{ the residual cell}} \right)$$

is valid in every behavioural model with attained débuts for the  $\alpha_i$ , where  $\Phi$  is the FS-target of QFIRSTSERVICE (read at  $n = 1$  with the empty co-obligation conjunction as  $\top$ , so  $\Phi = \alpha_1$ ). Reading: within the cutoff, either some first service has happened (and the co-obligations persist at original budgets), or nothing has been served and every obligation holds at its *true* residual.

**Theorem R49.1** (soundness of QFIRSTSERVICE SPLIT). *In every behavioural model with attained débuts for  $\alpha_1, \dots, \alpha_n$ , at every state  $x$ : if  $x \models A_{T_i} \alpha_i$  for all  $i$  and  $0 < c < \min_i T_i$ , then  $x \models A_c (\Phi \vee P)$ .*

*Proof.* Let  $\tau \in B_x$ . As in the QFIRSTSERVICE proof, attainment gives each obligation a least visit time  $t_i \leq T_i$  along  $\tau$ ; put  $t^* := \min_i t_i$ , attained at  $i_0$ . Split on the cutoff.

*Case  $t^* \leq c$ .* The QFIRSTSERVICE argument, verbatim, puts  $y := \tau(t^*)$  in  $\llbracket \Phi \rrbracket$ : it serves  $\alpha_{i_0}$ , and for  $i' \neq i_0$  every  $\sigma \in B_y$  inherits  $\sigma \llbracket \alpha_{i'} \rrbracket \leq T_{i'}$  through the fusion  $\tau \cdot_{t^*} \sigma \in B_x$ , the prefix being  $\alpha_{i'}$ -free below  $t^*$  by minimality. So  $\tau$  visits  $\llbracket \Phi \vee P \rrbracket$  at  $t^* \leq c$ .

*Case  $t^* > c$ .* Let  $y := \tau(c)$ ; we show  $y \in \llbracket P \rrbracket$ , so that  $\tau$  visits the disjunction at time  $c$ . Fix  $i, \sigma \in B_y, \varepsilon > 0$ . Fuse:  $\rho := \tau \cdot_c \sigma \in B_x$  by B3, so there is a  $\rho$ -visit of  $\alpha_i$  at some  $s < T_i + \varepsilon$ . The prefix is service-free through  $c$ : for  $s' < c$ ,  $\rho(s') = \tau(s')$ , and a visit

there would give  $t_i \leq s' < c < t^* \leq t_i$  — impossible; and the point at  $c$  itself is  $\rho(c) = \sigma(0) = \tau(c)$ , likewise unvisited (a visit at  $c$  would give  $t_i \leq c < t^*$ ). So  $s \geq c$  and  $\rho(s) = \sigma(s - c)$ : a  $\sigma$ -visit at time  $s - c < (T_i - c) + \varepsilon$  (subtract  $c$  across  $s < T_i + \varepsilon$ , using  $c < T_i$  to keep the residual budget a genuine nonnegative quantity). As  $\varepsilon$  was arbitrary,  $\sigma_{\llbracket \alpha_i \rrbracket} \leq T_i - c$ .  $\square$

*Remark R49.2* (each hypothesis, remarked).  $c < \min_i T_i$  keeps every residual budget strictly positive — the regime the law is stated for; at  $c = \min_i T_i$  the split degenerates (under attained débuts the served case always fires, since  $t^* \leq \min_i T_i$ ) and the residual row would carry  $A_0$ . Attainment is consumed only through  $t^*$  — and only the *served* case consumes it: the no-service case uses the visit  $s$  directly, never its infimum. That asymmetry is honest and sharp: over bare B1–B3 models the residual branch alone survives, and the schema as a whole fails — the countermodel (prose; not mechanized) retunes the QFIRSTSERVICE countermodel — the dense cluster moved, the escape-legality threshold lowered to match — and adds “lazy wings”: branches postponing every service to just inside the original budgets, legal precisely because the premise pins only original budgets before the cluster, defeating target and residual simultaneously along the spine. Attained débuts restore the dichotomy the case split runs on.

*Remark R49.3* (what the law buys). QFIRSTSERVICE can only re-issue original budgets at the service point; QFIRSTSERVICE SPLIT recovers the true residual  $T_i - c$  on the no-service branch, where the elapsed time is pinned by the cutoff rather than by an unknowable service instant. Iterated at successive cutoffs this derives the decision procedure’s deadline-tightening step exactly (its descent lemma), which is what closed the derivation side of the g<sub>nd</sub> completeness theorem. Independence: a six-state witness proves the law underivable from the FS-corrected basis for integer deadline menus, extended to half-integer menus by two certified witnesses; independence at finer denominators is open, and citation is bounded accordingly.

## 15.6 Streett Rules and the Specification Surface

### Rule 50. QSTREETTDEGENERATE (alias for QSTREETTBATTERY)

#### The rule (Steele metanotation)

as realized in the mechanized development; source row: QTSL-rules.toml — *QStreettDegenerate*. The metanotation statement is typeset by hand for notational quality; its mechanized ground truth is the Lean statement below, extracted from the sources at every build of this book and hash-bound. The rule *roster* is machine-checked (every mechanized rule tag round-trips to exactly one catalogue row); the statement *text* is editorial, checked by eye against the extracted Lean beside it.

$$\frac{\text{one QSTREETTBATTERY node at } \rho_i := \text{STrue for every pair} \\ (\text{absorbing families and } J_i \text{ syntactically empty; ranking decay off } \llbracket \varphi_i \rrbracket \text{ alone})}{\mathcal{M}, x_0 \in \{V_0 \leq y\} \models \text{SProbGE}(p, \text{PDwellStreett}(\text{PairBase}(\text{STrue}, \varphi_1), \dots, \text{PairBase}(\text{STrue}, \varphi_k)))}$$

the pair at request  $\top$  means  $\text{Inf}(\llbracket \varphi_i \rrbracket)$  — the classical recurrence certificate; the degenerate-pair specialization erases the tautological rows before emission, so the emitted kit is the recurrence kit row for row.

QSTREETTDEGENERATE is the recurrence rule in its compact spelling: to conclude, with probability at least  $p$ , that every response region is visited infinitely often (GF-shaped claims, the classical Büchi/recurrence certificate), instantiate the Streett bundle at the trivially-true request. It is an *alias* (né StreettDegenerate — the first sub-rule of the battery row): one QSTREETTBATTERY application, at request regions equal to the whole state space, is the entire unpacking — the emptiness it exploits is syntactic, not semantic. When every state requests, the finitely-many-requests disjunct of each pair is empty along the tail filter, the absorbing-certificate family and its carved-out sets  $J_i$  are vacuous, and the ranking decay row is demanded off the response region alone — so the degenerate-pair specialization erases exactly the tautological rows, and what the checker replays is the recurrence certificate, row for row. A producer uses it wherever the specification is recurrence rather than request-response fairness; nothing about the certificate synthesis changes except that the request machinery never materializes.

Scope, stated plainly: the bound statement below is the degenerate-instance witness `sound_QStreettDegenerate` (module `BernsteinLogicAux.QStreett` — one application of `sound_QStreettBattery` at request set `univ`, whose finitely-many-requests disjunct is empty along the tail filter; its conclusion is the recurrence event  $\Pr[\forall i, \text{Inf}(G_i)] \geq p$ , exactly the amended display's claim). The witness covers the rule at the *discrete-kernel profile* (a time-homogeneous Markov chain presented by a single step kernel); this entry once carried a conditional mark inherited from the bundle's continuous-time residue, and it goes the way the bundle's went: at the martingale-problem profile the bundle is discharged whole — strict-decrement rows included, hash-bound under the QSTREETTBATTERY entry — and the alias inherits that discharge the same way it inherits everything else, as one bundle application at request set `univ`, per the bundle section's profile remark. The payload-level unpack function is not among this edition's bound artefacts: the alias deliberately has no wire sort of its own (producers elaborate before emission), and the transport table in the proof is stated at the catalogued-field level.

**notes** The degenerate pair is also the honest cost anchor of the Streett-primitive design: on recurrence-shaped workloads the bundle emits the same rows a dedicated recurrence rule would, so the general rule costs nothing where the special case suffices — while the reverse specialization (recurrence-primitive, Streett by automaton product) would pay exponentially in the number of pairs.

## Correspondence (Steele display $\leftrightarrow$ Lean)

**reviewer-certified against the displayed texts** The dictionary below is a reviewer-certified statement of how the mechanized statements above interpret the displayed rule: display metavariable  $\mapsto$  Lean binder, each display hypothesis  $\mapsto$  the premise or side condition carrying it, the display conclusion  $\mapsto$  the goal — with any deliberate difference in width between display and mechanization named outright. Certification is recorded as a hash triple over (the displayed cell, the extracted statement texts, this dictionary's own text); if any of the three changes, this block turns amber until a reviewer re-certifies. The correspondence claim itself remains editorial — reviewer-grade, not machine-checked; its machine-checked successor types each soundness statement against the rule as a structured object, and supersedes this block per rule as it lands.

The displayed conclusion  $\mathcal{M}, x_0 \in \{V_0 \leq y\} \models \text{SProbGE}(p, \text{PDwellStreett}(\text{PairBase}(\text{STrue}, \varphi_1), \dots, \text{PairBase}(\text{STrue}, \varphi_k)))$   $\mapsto$   $\text{ofReal } p \leq \text{pathMeasure } K \times \{\omega \mid \forall i, \exists^f n \text{ in atTop}, \omega n \in G i\}$  for every start with  $x \in D$  and  $V_0 x \leq \text{thr}$  (the Lean source's identifier for the display's  $y$ ) — the recurrence event, with the  $\text{STrue}$ -requests *erased at the statement level*, not merely in the proof: no request binder exists in `sound_QStreettDegenerate` at all, which is the display's “absorbing families and  $J_i$  syntactically empty” carried into the type. The alias tier is visible in the proof term: one `sound_QStreettBattery` application at `Rq := fun _ => Set.univ`, whose frequently-clause is discharged by `univ-membership`.

- the inherited  $V_0$  QSafetyBattery kit  $\mapsto$  the four kernel-integral rows verbatim:  $hV_{\circ}drift$  (interior),  $hV_{\circ}floor$  (floor on  $U \cap \bar{D}$ ),  $hV_{\circ}nonneg$  (on  $\bar{D}$ ), with  $hV_{\circ}int$  the undisplayed integrability rider, plus the hull/fail-closed side conditions  $hR3/hR4$  and the threshold  $h\theta : p + thr \leq 1$  — the battery pattern, unchanged.
- “ranking decay off  $\llbracket \varphi_i \rrbracket$  alone”  $\mapsto hWdriftR : \forall i, \forall y \in D, y \notin U \rightarrow y \notin G_i \rightarrow \int z, W i z \partial K y \leq W i y - \varepsilon_i$  — one generator row where the bundle carries two: the request-conditioned decay and the off-response non-increase coincide when every state is a request, and the statement asks only the merged row (the proof re-splits it for the bundle).
- $nonneg + upper-bound$  rows  $\mapsto hW0/hWC$  on  $\bar{D}$ ; strictness  $\mapsto h\varepsilon : \forall i, 0 < \varepsilon_i$  — note the specialized statement takes per-pair  $\varepsilon_i$ , mildly wider than the display's single  $\varepsilon_0$ .
- the measurability pack ( $hD/hDbar/hU/hV_{\circ}/hG/hW$ ) is undisplayed profile regularity, per the battery precedent.

Width note: this alias's warrant is inherited from the bundle at both profiles (hash-bound at the discrete-kernel profile; the martingale-problem discharge, strict rows included, hash-bound under the bundle entry); the producer-side erasure of tautological rows before emission is compile behaviour with no Lean counterpart — correctly, since the certified statement never receives the tautological rows to begin with.

## Lean verifier receipts

module BernsteinLogicAux.QStreett; bound build 469881beb770... (bound from receipt 9d1d848e0ba1718a, 2026-07-29T01:03:31Z). A receipt records that named checking layers accepted a build: (module, compiled-artifact SHA-256, environment SHA-256, checker layers), minted when the checking gate ran; the store receipts attesting the bound build are listed with the layers each run credited. Nothing here asks the reader to trust the store: every layer is an independently runnable program over the quoted sources — rebuild the module and re-run the checkers to reproduce the verdict. Receipts attesting superseded builds credit no layer and are omitted from this rendering (the count of omissions, if any, is noted below).

| receipt          | minted               | layers                             | status  |

hardened (safe\_verify (hardened screen)) current

decorrelated (lean4export + nanoda (decorrelated kernel)) current

comparator: none no fixture in the three-implementation comparator harness (compiled / kernel-interpreted / reference-interpreted) exercises this rule.

## HOL4 statement

### OUT OF SCOPE BY DESIGN

Out of scope for the HOL side *by design*, not by backlog: the rule is a producer-side respelling that unpacks to a single QSTREETTBATTERY node before any certificate is emitted, so no wire object can ever contain a QSTREETTDEGENERATE node — the HOL statement that would verify a degenerate-request bundle is the bundle's own (itself absent today, for the reason given in that section: the satisfaction stratum has no HOL artefact). Checked against the HOL sources: the bern\_catalogue theory is the base-calculus checker cone and carries nothing Streett-shaped.

## HOL verifier receipts

### NONE

no HOL verification receipt exists for this rule.

## Proof

Genre: alias rule (tier 3) — a respelling template. This section additionally states, once for the whole batch of satisfaction-level aliases, the general template those sections share; the QSTREETTCMPLREQUEST, QSTREETTTARGETCELLCOLLAPSE, QNNFREWRITE, QSTREETTREQUESTNNF, QAVOID, QSTREETTGF, QSTREETTFG, and QNEGFALIAS sections reference it by this section's rule name instead of restating it.

**Recipe R50.1** (the satisfaction-level alias template). An alias rule  $A$  at the satisfaction stratum is warranted by a  $1 \rightarrow 1$  unpack into a single application of a target rule  $T$  (or, for the spec-surface rewrites, into a single definitional denotation equality): the  $A$ -node and its image conclude the same judgment from the same premise data, payload transported, nothing derived. Soundness is then a corollary,  $\text{sound}_A = \text{unpack} \circ \text{sound}_T$ , and the certificate format need never carry  $A$ : producers elaborate before emission. The five artefacts an alias owes this book are the same as at the base stratum (the SMALLGAIN section is the model): the unpack, the filled-in target application, the payload-transport table, the exactness identity, and the soundness corollary. One honest divergence from the base-stratum model, stated once here: no alias of this batch has a *verified payload function* among this edition's bound artefacts. The transport tables of this batch are therefore stated at the catalogued-field level, and the unpack-function slot of each alias says so plainly; where a discrete-profile *semantic* witness exists in the auxiliary Lean development it is named (the soundness content is machine-checked even though the payload-level function is not), with its statement pin riding the bindings record wherever the per-section text says hash-bound, and where none exists the status is stated as filed. In every case it is the payload-level slot, never the semantic witness, that remains outside the bound warrant; the per-section text says which case holds.

**Recipe R50.2** (the filled-in application — QSTREETTDEGENERATE rewritten into its QSTREETTBATTERY instance). A degenerate node claims, from the confinement certificate  $V_0$  and per-region ranking certificates  $(W_i, \varepsilon_i)$ , that with probability  $\geq p$  every response region  $G_i$  is visited infinitely often. Its image is the single bundle node at request regions  $R_i := S$  (every state requests):

$$\frac{\text{confinement rows for } V_0 \quad \{\vdash \text{nonincrease of } W_i \text{ off } G_i\} \quad \{\vdash \varepsilon_i\text{-decay of } W_i \text{ off } G_i\} \quad (\text{the request row at } R_i = S) \quad p + y \leq 1 \text{ (threshold tie)}}{\mathcal{M}, x_0 \in \{V_0 \leq y\} \models \text{SProbGE}(p, \text{PDwellStreett}(\text{PairBase}(\text{STrue}, \varphi_1), \dots, \text{PairBase}(\text{STrue}, \varphi_k)))} \quad \text{QSTREETTBATTERY}$$

Discharging the bundle's obligations at this instance: the request regions are measurable trivially; the decay row *subsumes* the nonincrease row (off  $G_i$ , every state is a request state, so nonincrease follows from decay with the kit's  $\varepsilon_i > 0$  — nonnegativity is all the subsumption spends); the absorbing families  $(V_i, \gamma_i)$  and carved sets  $J_i$  are vacuous — each  $J_i$  lives inside  $I \setminus \llbracket \rho_i \rrbracket$ , with  $I$  the confinement region of the bundle's carved-scope formula, and at  $\rho_i = \top$  that base is  $I \setminus S = \emptyset$ , so  $J_i = \emptyset$  syntactically, the rows carved to  $J_i$  and to off-request regions are rows over the empty region, and the specialization targets the bundle's conservative (absorber-free) scope — the scope its ranking-route soundness theorem consumes — so no request-region absorber obligation survives. The dead premise slots are honestly dead, and the degenerate-pair specialization pass erases them before emission.

### Recipe R50.3 (payload transport, catalogued-field level).

#### degenerate node

$V_0$  rows, threshold, init  
response regions  $G_i$ , certificates  $(W_i, \varepsilon_i)$   
shared side conditions (hull, fail-closed) + measurability pack  
—  
—  
decay rows off  $G_i$

#### QSTREETTBATTERY node

verbatim  
verbatim (bound rows  $0 \leq W_i \leq C_i$  and strict  $\varepsilon_i > 0$  included)  
verbatim (the battery pattern's)  
request regions  $:= S$  (each pair; measurable trivially)  
absorbing families: empty;  $J_i = \emptyset$  (syntactic)  
request-decay rows (at  $R_i = S$ ); nonincrease subsumed

Unpack-function slot: no verified payload function in this edition (Recipe R50.1); the semantic witness exists — `sound_QStreettDegenerate`, one `sound_QStreettBattery` application at request set `univ` (auxiliary module; hash-bound in this edition).

**Proposition R50.4** (the exactness identity). *For every path  $\omega$  and pair  $i$ , at  $R_i = S$ :*

$$(\exists^\infty n, \omega_n \in S) \Rightarrow (\exists^\infty n, \omega_n \in G_i) \iff \exists^\infty n, \omega_n \in G_i.$$

*Proof.* The hypothesis  $\exists^\infty n, \omega_n \in S$  holds of every path (every time is a request time), so the implication and its conclusion are equivalent — one line, which is the point. Equivalently, in acceptance vocabulary: the finitely-many-requests disjunct  $\text{Fin}(S)$  is empty along the tail filter, so the pair condition  $\text{Fin}(R_i) \vee \text{Inf}(G_i)$  collapses to  $\text{Inf}(G_i)$ .  $\square$

**Proposition R50.5** (soundness corollary). *Under the degenerate node's rows,  $\mu_x\{\omega \mid \forall i, \exists^\infty n, \omega_n \in G_i\} \geq p$ .*

*Proof.* Apply the bundle's soundness theorem (the QSTREETTBATTERY section's — at its proven scope, the discrete-kernel profile and conservative ranking scope; the bundle's martingale-problem discharge transfers to this alias the same way, one application at the trivially-true request) at  $R_i = S$  and rewrite the event by Proposition R50.4. There is no other content — the alias genre working as intended. (Machine-checked as sound\_QStreettDegenerate; hash-bound in this edition.)  $\square$

*Remark R50.6* (this is the Büchi case). A Büchi condition *is* the one-pair Streett condition with trivially-true request, so this alias is where the classical recurrence certificate lives inside the Streett-primitive design. Deterministic Büchi automata recognize only limit languages [150], so the reverse direction — expressing a general Streett condition Büchi-primitively — is not a respelling at all but an automaton re-encoding, exponential in the number of pairs for the classical translations; the asymmetry is why the bundle, not the recurrence rule, is the primitive ([226, 232]; see the bundle section's remark).

| proof step             | formal anchor                                                                                      |
|------------------------|----------------------------------------------------------------------------------------------------|
| Recipe R50.2 target    | the QSTREETTBATTERY section, Theorem & hypotheses (H1)–(H5)                                        |
| Proposition R50.4      | syntactic; no formal anchor needed (one line of filter algebra)                                    |
| Proposition R50.5      | sound_QStreettDegenerate (BernsteinLogicAux.QStreett; machine-checked, hash-bound in this edition) |
| no wire tag, by design | producers elaborate before emission (Recipe R50.1)                                                 |

## Rule 51. QSTREETTCMPLREQUEST (admissible rule)

### The rule (Steele metanotation)

as realized in the mechanized development; source row: QTSL-rules.toml — *QStreettCmplRequest*. The metanotation statement is typeset by hand for notational quality; its mechanized ground truth is the Lean statement below, extracted from the sources at every build of this book and hash-bound. The rule *roster* is machine-checked (every mechanized rule tag round-trips to exactly one catalogue row); the statement *text* is editorial, checked by eye against the extracted Lean beside it.

$$\frac{\text{a QSTREETTBATTERY kit at certified regions } (R_i, G_i) \quad \{\llbracket \text{cmpl } \rho_i \rrbracket \subseteq R_i\} \text{ (requests over-approximated)} \quad \{G_i \subseteq \llbracket \varphi_i \rrbracket\} \text{ (responses under-approximated)}}{\mathcal{M}, x_0 \in \{V_0 \leq y\} \models \text{SProbGE}(p, \text{PDwellStreett}(\text{PairCmpl}(\rho_1, \varphi_1), \dots))}$$

requests sit on the hypothesis side of each pair implication, so the orientation swap of the complement (the workhorse judgment certifies under-approximations; complements arrive as over-approximations) is exactly the sound direction, for free.

QSTREETTCMPLREQUEST lets a Streett pair carry its request as a *complement*: the pair  $(\text{cmpl } \rho_i, \varphi_i)$  asks that if states *outside*  $\llbracket \rho_i \rrbracket$  recur forever, responses recur forever. The satisfaction judgment's workhorse orientation certifies regions that *under-approximate* a formula's denotation — one orientation, deliberately: the complement of an under-approximation is an *over-approximation*, so a complement-typed request arrives with the opposite orientation for free. The rule (né StreettCmplRequest) is *admissible*, not *alias*: its unpacking is one QSTREETTBATTERY node *plus* region-weakening premises — the certified request regions over-approximate the complement denotations, the certified response regions under-approximate the response denotations — and the direction check that makes this the sound weakening is genuine content, not transport. Requests sit on the hypothesis side of each pair implication and responses on the conclusion side, so over-approximating requests and under-approximating responses each *weaken the claimed event*: any path satisfying the certified pair satisfies the semantic pair. What the checker recomputes: nothing new in kind — the weakening premises are ordinary region-containment rows it already knows how to verify, and the complement itself is consumed at the region-atom level (the atom dualities of the QNNFREWRITE section), never as a formula node.

Scope, stated plainly (this entry is marked *conditional*): the bound statements below are the discrete-profile witnesses — the event-level direction lemma `streett_event_mono` (two monotonicity steps, exactly the two lines the recipe below typesets) and the assembled bundle-through-formula-tie `sound_QStreettBattery_tie` (requests over-approximated, responses under-approximated, concluded over the semantic satisfaction predicates), both in module `BernsteinLogicAux.QStreett`, plus the atom-level complement step `denot_elimNeg` in `BernsteinLogicAux.NNFDuality`. One named residue keeps the flag — and it is this entry's own, not the bundle's (whose continuous-time residue is discharged whole at the martingale-problem profile, strict rows included, hash-bound under the QSTREETTBATTERY entry): the continuous-time face of the complement step remains prose. At the general-stochastic-hybrid profile, consuming a complemented request requires fine-topology regularity of the region (that the region is nearly Borel and contains its regular points), which is argued in the design record.

**notes** Why one orientation of the workhorse judgment suffices, in one line: an under-approximating region calculus is closed under the connectives the rules consume, and where a complement appears, the swap to over-approximation is exactly what the hypothesis side of an implication wants — demanding a second, over-approximating judgment kind would duplicate every rule for zero content.

## Correspondence (Steele display ↔ Lean)

**reviewer-certified against the displayed texts** The dictionary below is a reviewer-certified statement of how the mechanized statements above interpret the displayed rule: display metavariable  $\mapsto$  Lean binder, each display hypothesis  $\mapsto$  the premise or side condition carrying it, the display conclusion  $\mapsto$  the goal — with any deliberate difference in width between display and mechanization named outright. Certification is recorded as a hash triple over (the displayed cell, the extracted statement texts, this dictionary's own text); if any of the three changes, this block turns amber until a reviewer re-certifies. The correspondence claim itself remains editorial — reviewer-grade, not machine-checked; its machine-checked successor types each soundness statement against the rule as a structured object, and supersedes this block per rule as it lands.

Three bound statements, three display constituents. The orientation-swap kernel — the flavor text's “exactly the sound direction, for free” —  $\mapsto \text{streett\_event\_mono}$ :  $Rq \sqsubseteq Rqhat$  (requests over-approximated) and  $Ghat \sqsubseteq G$  (responses under-approximated) transport the per-pair Streett implication pathwise; two `Frequently.monos`, the priced two lines, axiom-light and *deterministic* — no measure appears.

- the assembled rule  $\mapsto \text{sound\_QStreettBattery\_tie}$ : the full bundle kit (the battery-pattern binder block, as on the degenerate-request page) plus the two tie hypotheses, and the polarity pair is carried exactly —  $hreq : \forall i y, reqSat\ i\ y \rightarrow y \in Rq\ i$  (the certified region *over*-approximates the semantic request truth set: for `cmpl`-typed requests this is the atom-level complement-elimination inclusion  $\llbracket \text{cmpl } \varphi \rrbracket \supseteq \llbracket \varphi \rrbracket^c$ ) and  $hresp : \forall i, \forall y \in G\ i, respSat\ i\ y$  (responses *under*-approximated). The conclusion event quantifies over the semantic predicates `reqSat/respSat`, of which *no measurability is asked* (the measurable objects are the certified regions — the `QSafetyBattery sat` pattern), and both tie hypotheses are safe-direction widenings in the `QClosure` polarity sense.
- the atom-level complement step  $\mapsto \text{denot\_elimNeg}$  (the NNF module): where each dual atom denotes the complement, consuming a `cmpl`-typed request through swapped atoms preserves the region — the lawfulness clause cited at `QStreettRequestNnf`'s consumption boundary (its flavor text).

Width note: the conditional mark's one remaining residue, exactly as the roster carries it — the fine-topology content of the complement step at the general-stochastic-hybrid profile (nearly-Borel regions,  $E' \subseteq E$ ), which remains design-note prose with no bound counterpart; the bundle side's former continuous-time residue is discharged and hash-bound under the bundle entry. `streett_event_mono` is itself profile-free (pure path logic); the profile enters only with the assembled tie.

## Lean verifier receipts

module `BernsteinLogicAux.QStreett`; bound build 469881beb770... (bound from receipt 9d1d848e0ba1718a, 2026-07-29T01:03:31Z). A receipt records that named checking layers accepted a build: (module, compiled-artifact SHA-256, environment SHA-256, checker layers), minted when the checking gate ran; the store receipts attesting the bound build are listed with the layers each run credited. Nothing here asks the reader to trust the store: every layer is an independently runnable program over the quoted sources — rebuild the module and re-run the checkers to reproduce the verdict. Receipts attesting superseded builds credit no layer and are omitted from this rendering (the count of omissions, if any, is noted below).

**comparator: none** no fixture in the three-implementation comparator harness (compiled / kernel-interpreted / reference-interpreted) exercises this rule.

## HOL4 statement

### NO HOL STATEMENT YET

Absent, precisely located: the rule's realization rides the typed request field of the Streett bundle — and the HOL4 development (bern\_catalogue, the base-calculus checker cone) carries nothing at the satisfaction stratum, so there is no HOL-side wire object for a checker to consume. A HOL statement becomes meaningful only after the extension stratum is ported; the weakening rows themselves are ordinary containment sequents the base checker already covers. Checked against the HOL sources this edition.

## HOL verifier receipts

### NONE

no HOL verification receipt exists for this rule.

## Proof

Genre: admissible rule (tier 2) — a proof-tree-rewriting recipe (the general admissible template is stated in the PCONSTEXACT section; the batch-level honesty clause about absent payload functions is Recipe R50.1 of the QSTREETTDEGENERATE section and applies here verbatim).

**Recipe R51.1** (the QSTREETTCMPLREQUEST instance — one node, one bundle, per-pair weakening premises). A node concluding  $\mathcal{M}, x_0 \in \{V_0 \leq y\} \models \text{SProbGE}(p, \text{PDwellStreett}(\text{PairCmpl}(\rho_1, \varphi_1), \dots))$  rewrites to the derivation fragment

$$\frac{\begin{array}{c} \text{the bundle kit at certified regions } (R_i, G_i) \\ \{ \llbracket \text{cmpl } \rho_i \rrbracket \subseteq R_i \}_i \text{ (request weakening)} \quad \{ G_i \subseteq \llbracket \varphi_i \rrbracket \}_i \text{ (response weakening)} \end{array}}{\mathcal{M}, x_0 \in \{V_0 \leq y\} \models \text{SProbGE}(p, \text{PDwellStreett}(\text{PairCmpl}(\rho_1, \varphi_1), \dots))} \text{QSTREETTBATTERY}$$

where the request-weakening premises are supplied for free by the orientation swap: a certified under-approximation  $A_i \subseteq \llbracket \rho_i \rrbracket$  yields the over-approximation  $A_i^c \supseteq \llbracket \rho_i \rrbracket^c$ , and  $R_i := A_i^c$  is a region atom by the atom dualities (QNNFREWRIE section) wherever  $A_i$ 's atom class carries a dual — the ordered-comparison classes, which are the shapes normalized request bodies produce; an over-approximation of any other shape is simply supplied as its own certified region — and the complement is consumed at the atom level, never as a formula node. The weakening premises are ordinary containment rows the checker already knows how to verify; nothing new *in kind* is recomputed.

**Proposition R51.2** (the direction lemma — two lines). *Fix a path  $\omega$  and one pair. If the certified regions satisfy  $\text{Rq} \subseteq \widehat{\text{Rq}}$  (requests over-approximated when read semantic-to-certified) and  $\widehat{G} \subseteq G$  (responses under-approximated), then*

$$\left[ (\exists^\infty n, \omega_n \in \widehat{\text{Rq}}) \Rightarrow (\exists^\infty n, \omega_n \in \widehat{G}) \right] \Rightarrow \left[ (\exists^\infty n, \omega_n \in \text{Rq}) \Rightarrow (\exists^\infty n, \omega_n \in G) \right].$$

*Proof.* Frequent membership is monotone in the set: frequent  $\text{Rq}$ -visits are frequent  $\widehat{\text{Rq}}$ -visits (hypothesis side, first monotonicity), and frequent  $\widehat{G}$ -visits are frequent  $G$ -visits (conclusion side, second monotonicity). Two applications of monotonicity — which is the entire lemma, and why the weakening premises are the only new obligations of the rewrite. (Machine-checked as `streett_event_mono`; hash-bound in this edition.)  $\square$

**Proposition R51.3** (semantic warrant of the rewrite). *Under the bundle kit's rows and the weakening premises of Recipe R51.1, the concluded judgment holds: with probability  $\geq p$ , every semantic pair implication  $(\exists^\infty \text{ states outside } \llbracket \rho_i \rrbracket) \Rightarrow (\exists^\infty \text{ states in } \llbracket \varphi_i \rrbracket)$  is satisfied.*

*Proof.* The bundle theorem gives the certified-region Streett event probability  $\geq p$ ; Proposition R51.2, applied per pair with  $R_q := \llbracket \text{cmpl } \rho_i \rrbracket \subseteq R_i$  and  $G_i \subseteq \llbracket \varphi_i \rrbracket$ , includes that event in the semantic one; the certified event is measurable (its regions are the kit's), and the path measure, read as outer measure on the possibly-nonmeasurable semantic event, is monotone — the lower bound transfers. (Machine-checked, assembled, as `sound_QStreettBattery_tie`; hash-bound in this edition.)  $\square$

*Remark R51.4* (why the orientations are not symmetric, and not optional). Swap either direction and the rule is unsound. If a certified request region *under*-approximated the complement, a path could request infinitely often in the semantic sense while the certificate sees only finitely many requests — the certified pair implication holds vacuously, the semantic one fails. Dually, a response region *over*-approximating  $\llbracket \varphi_i \rrbracket$  lets certified “responses” land outside the actual response set. The hypothesis-side / conclusion-side asymmetry of implication is the entire content of the direction check, and it is why the complement orientation swap — which produces exactly over-approximations — is fitted to requests and to nothing else.

*Remark R51.5* (profile residue). At the discrete-kernel profile the lemma chain above is complete, machine-checked, and hash-bound in this edition. At the continuous-time martingale-problem profile the bundle side is discharged whole per the bundle section's profile remark (confinement, zero-decrement, and strict-decrement rows; hash-bound there); what keeps this entry's conditional mark is the complement consumption's own fine-topology content (regular points of the complement region), which remains prose in the design record — a residue of this entry's own, not of the bundle's.

| proof step                                          | formal anchor                                                                                                                                     |

## Rule 52. QSTREETTTARGETCELLCOLLAPSE (alias for QSTREETTBATTERY)

### The rule (Steele metanotation)

as realized in the mechanized development; source row: QTSL-rules.toml — *QStreettTargetCellCollapse*. The metanotation statement is typeset by hand for notational quality; its mechanized ground truth is the Lean statement below, extracted from the sources at every build of this book and hash-bound. The rule *roster* is machine-checked (every mechanized rule tag round-trips to exactly one catalogue row); the statement *text* is editorial, checked by eye against the extracted Lean beside it.

$$\frac{\mathcal{K}, \text{slab} \vdash W_i \geq 0}{\mathcal{K}, \text{slab} \vdash g \circ W_i \leq W_i} g(\text{slab}) \subseteq T, W_i \equiv 0 \text{ ON } T \text{ (G5, RECOMPUTED)}$$

$\mathcal{K}$  ranges over QSTREETTBATTERY kits; the slab region left of the turnstile scopes both sequents.

a deduction rule between sequents: the kits demand the nonnegativity premise anyway, and under the side conditions (checker-recomputed, never a trusted annotation) the reset lands where the ranking certificate is identically zero, so the conclusion follows pointwise from the premise. On slabs whose resets leave the zero region the side condition fails and the full guard row is owed as usual.

QSTREETTTARGETCELLCOLLAPSE is a deduction rule between sequents of one QSTREETTBATTERY kit context (né StreettTargetCellCollapse): with  $\mathcal{K}$  the premise metavariable ranging over bundle kits, it derives the ranking-guard row  $g \circ W_i \leq W_i$  on a guard slab from the nonnegativity row  $W_i \geq 0$  there — a row the kit demands anyway — under two side conditions: the containment of the reset image in the zero-convention region ( $g(\text{slab}) \subseteq T$ , with  $W_i \equiv 0$  on  $T$ ). The rule is sound because under the side conditions the conclusion's left side is literally zero on the slab. Both side conditions are recomputed geometric checks, never trusted annotations — which is also why the rule cannot be abused: on a slab whose resets leave the zero region, the side condition fails and the full guard row is owed as usual.

Mechanization state, plainly: the bound statement below is the one-line witness `ranking_guard_collapse` (module `BernsteinLogicAux.QStreett`) — under the zero-on-target convention and the recomputed containment, the guard row follows from the nonneg row on the slab, which is the entirety of the rule's semantic claim (pure state-space set algebra: no kernel, no profile, no probability enters, so no profile residue attaches and the entry carries no conditional flag). The payload-level unpack owes no sort of its own — the extension certificate schema's adjudication of the batch family (QSTREETTDEGENERATE section, Recipe R50.1): the collapse is a citation (the guard row cites the nonneg row's proof), and the containment is a recomputed side condition of the battery walk, never a stored row — so there is nothing to elaborate, by design.

**notes** The checker's implementation is citation-shaped, deliberately decoupled from the deduction-rule presentation: no wire object ever carries a collapse node — a producer that has already discharged the nonneg row cites it where the guard row was owed and emits nothing new, one row to one row. Tier flag, carried honestly from the source catalogue: that one-to-one citation shape is the alias tiering, but the licensing side condition is a recomputed containment — if side-condition weight is ever ruled heavier than the alias criterion intends, the rule re-tiers admissible with machinery unchanged. Flagged, not forced.

### Lean statement

BernsteinLogicAux.QStreett . `ranking_guard_collapse`

statement bound

```
/-- **`QStreettTargetCellCollapse` (T9c)**: when the reset of a guard transition
lands inside a region where the ranking certificate is identically zero (the
`W_i ≡ 0`-on-target-cells convention, G5), the ranking-guard row
`W (g y) ≤ W y` collapses to the nonneg row `0 ≤ W y` — one row to one row,
under the recomputed containment side-condition `g '' slab ⊆ T`. -/
theorem ranking_guard_collapse {W : S → ℝ} {T slab : Set S} {g : S → S}
  (hzero : ∀ y ∈ T, W y = 0) (himg : ∀ y ∈ slab, g y ∈ T) :
  ∀ y ∈ slab, 0 ≤ W y → W (g y) ≤ W y
```

### Correspondence (Steele display ↔ Lean)

**reviewer-certified against the displayed texts** The dictionary below is a reviewer-certified statement of how the mechanized statements above interpret the displayed rule: display metavariable  $\mapsto$  Lean binder, each display hypothesis  $\mapsto$  the premise or side condition carrying it, the display conclusion  $\mapsto$  the goal — with any deliberate difference in width between display and mechanization named outright. Certification is recorded as a hash triple over (the displayed cell, the extracted statement texts, this dictionary's own text); if any of the three changes, this block turns amber until a reviewer re-certifies. The correspondence claim itself remains editorial — reviewer-grade, not machine-checked; its machine-checked successor types each soundness statement against the rule as a structured object, and supersedes this block per rule as it lands.

One bound statement, and the displayed deduction rule is its literal shape: `ranking_guard_collapse` concludes  $\forall y \in \text{slab}, \emptyset \leq W y \rightarrow W (g y) \leq W y$  — the premise sequent as the antecedent, the concluded ranking-guard row as the consequent, per point of the slab. The two licensing conditions map as:  $W_i \equiv 0$  on target cells  $\mapsto \text{hzero} : \forall y \in T, W y = \emptyset$  (the G5 convention as a hypothesis), and the recomputed containment  $g(\text{slab}) \subseteq T \mapsto \text{himg} : \forall y \in \text{slab}, g y \in T$  — consumed as a hypothesis, recomputed checker-side, which is the tier-ambiguity flag's exact locus rendered as a binder. Width note: the statement is one line over arbitrary sets and an arbitrary reset map  $g : S \rightarrow S$  — no slab geometry, no polynomiality of  $W$ , no guard structure — strictly wider than the displayed instance, safe direction; the failure branch the flavor text names (resets leaving the zero region owe the full guard row) is representable precisely as `himg` failing, whereupon the theorem offers nothing — refusal-shaped, as it should be.

## Lean verifier receipts

module BernsteinLogicAux.QStreett; bound build 469881beb770... (bound from receipt 9d1d848e0ba1718a, 2026-07-29T01:03:31Z). A receipt records that named checking layers accepted a build: (module, compiled-artifact SHA-256, environment SHA-256, checker layers), minted when the checking gate ran; the store receipts attesting the bound build are listed with the layers each run credited. Nothing here asks the reader to trust the store: every layer is an independently runnable program over the quoted sources — rebuild the module and re-run the checkers to reproduce the verdict. Receipts attesting superseded builds credit no layer and are omitted from this rendering (the count of omissions, if any, is noted below).

| receipt          | minted               | layers                             | status  |

- hardened (safe\_verify (hardened screen)) current
- decorrelated (lean4export + nanoda (decorrelated kernel)) current

comparator: none no fixture in the three-implementation comparator harness (compiled / kernel-interpreted / reference-interpreted) exercises this rule.

## HOL4 statement

### OUT OF SCOPE BY DESIGN

Out of scope for the HOL side *by design*: the rule rewrites one premise row of a bundle kit into another *before* emission — no wire object ever contains a collapse node, and the surviving row is an ordinary base-calculus sequent the base checker already covers. The HOL statement that would matter is the bundle's own, absent for the reasons given in that section. Checked against the HOL sources: the `bern_catalogue` theory carries nothing Streett-shaped.

## HOL verifier receipts

### NONE

no HOL verification receipt exists for this rule.

## Proof

Genre: alias rule (tier 3); the batch's shared template, including the honesty clause about absent payload functions, is Recipe [R50.1](#) of the `QSTREETTDEGENERATE` section. This section's rule is stated in deduction-rule form — the respelling content is carried by the payload-transport recipe and the checker's citation-shaped implementation, noted there.

**Recipe R52.1** (the rule — a deduction between kit sequents). Fix a `QSTREETTBATTERY` kit context  $\mathcal{K}$ , a pair  $i$ , a guard transition with reset map  $g$  and guard slab  $\text{slab}$ , and let  $T$  be a region on which the kit's convention  $W_i \equiv 0$  holds (the target cells). The rule derives the ranking-guard row from the nonnegativity row the kit demands anyway — the kit's bound rows live on the hull  $\bar{D}$ , so

on guard slabs inside the hull the premise below is a row already owed, while a slab outside them simply owes its premise sequent separately; the deduction as displayed takes the on-slab sequent itself as premise either way:

$$\frac{\mathcal{K}, \text{slab} \vdash W_i \geq 0}{\mathcal{K}, \text{slab} \vdash g \circ W_i \leq W_i} \quad g(\text{slab}) \subseteq T, W_i \equiv 0 \text{ ON } T \text{ (G5, RECOMPUTED)}$$

Both side conditions are checker-recomputed (the G5-convention check), never producer-supplied. The premise metavariable does the honest work: premise and conclusion are sequents of the *same* kit context, so admitting the rule claims exactly that any kit admitting the premise admits the conclusion — Proposition R52.4, and nothing else.

**Recipe R52.2** (payload transport, catalogued-field level).

| collapse node                                | bundle kit row                                                                                                         |
|----------------------------------------------|------------------------------------------------------------------------------------------------------------------------|
| guard row $(W_i, g, \text{slab})$            | the kit's nonneg row for $W_i$ on slab, cited (licit where the slab lies in the cited row's region)                    |
| containment $g(\text{slab}) \subseteq T$     | recomputed side-condition (never producer-supplied)                                                                    |
| zero convention $W_i \equiv 0 \text{ on } T$ | the kit's target-cell convention, verbatim (that it holds on $T$ is the recomputed G5 check, not a trusted annotation) |

The checker's implementation is citation-shaped: a producer that has already discharged the nonnegativity row cites it where the guard row was owed, and emits nothing new — one row to one row, which is the alias tiering. Presentation and implementation are deliberately decoupled: the rule *is* the deduction above; the citation is how a certificate spells an application of it. Unpack-function slot: nothing to elaborate, by design — the collapse is a citation (the guard row cites the nonneg row's proof) and the containment is a recomputed side condition, never a stored row; the semantic witness `ranking_guard_collapse` (auxiliary module) is hash-bound in this edition.

**Proposition R52.3** (the exactness identity — one line). *For every  $y \in \text{slab}$ : if  $g(y) \in T$  and  $W_i \equiv 0 \text{ on } T$  and  $0 \leq W_i(y)$ , then  $W_i(g(y)) = 0 \leq W_i(y)$ .*

*Proof.* Substitution — the displayed chain is the proof. The guard row's left side is identically zero on the slab, so the guard row and the nonneg row assert the same inequality there.  $\square$

**Proposition R52.4** (soundness corollary — admissibility of the rule). *Any bundle kit admitting the nonneg row on the slab admits the ranking-guard row on the slab — the displayed rule, read as a claim; hence every conclusion drawn through `QSTREETTBATTERY` from the collapsed kit is drawn from the full kit, with the bundle's own soundness theorem as warrant.*

*Proof.* Proposition R52.3 produces the guard row pointwise from the nonneg row under the side conditions — that collapse is the machine-checked content (`ranking_guard_collapse`; hash-bound in this edition), and it is the whole of what this section proves. The guard row is consumed *upstream* of the flattened kernel: for a hybrid presentation it is one of the base-calculus sequents from which the kernel-integral ranking rows — the bundle kit's H4, which the bundle theorem is what actually consumes — are assembled by the presentation-to-kernel compile bridge (the safety battery's staged form carries that bridge as its explicit `hmix` hypothesis; the bundle theorem takes the compiled kernel and its H4 rows directly), never re-proven here. The corollary therefore lives at the kit stratum: the collapsed kit discharges every base-calculus obligation the full kit's guard row was owed for, and every conclusion drawn through `QSTREETTBATTERY` whose compile bridge owed that guard row is drawn from the full kit, the bundle's own soundness theorem — its assembly hypothesis unchanged — supplying the rest.  $\square$

*Remark R52.5* (why the side-condition is not decoration). Drop the containment and the collapse is unsound: a reset landing at a state with  $W_i(g(y)) > W_i(y)$  (outside the zero region) breaks the upstream derivation of the ranking generator rows that the bundle's telescoping lemma consumes — the certificate could be pumped back up at each guard crossing, and the summability of un-responded requests (`QSTREETTBATTERY` section) fails. The containment is checker-recomputed for precisely this reason; its weight is the tier flag recorded in the commentary.

| proof step                                 | formal anchor                                                                                                |
|--------------------------------------------|--------------------------------------------------------------------------------------------------------------|
| Recipe R52.1 premise context $\mathcal{K}$ | the <code>QSTREETTBATTERY</code> section's kit (H4 rows)                                                     |
| Proposition R52.3                          | <code>ranking_guard_collapse</code> ( <code>BernsteinLogicAux.QStreett</code> ; machine-checked, hash-bound) |
| side conditions                            | the zero-on-target containment, recomputed (the bundle's G5-convention check)                                |

## Rule 53. QN<sub>NF</sub>REWRITE (alias rule)

### The rule (Steele metanotation)

as realized in the mechanized development; source row: QTS<sub>L</sub>-rules.toml — *QN<sub>NF</sub>Rewrite*. The metanotation statement is typeset by hand for notational quality; its mechanized ground truth is the Lean statement below, extracted from the sources at every build of this book and hash-bound. The rule *roster* is machine-checked (every mechanized rule tag round-trips to exactly one catalogue row); the statement *text* is editorial, checked by eye against the extracted Lean beside it.

$$\begin{array}{llll} \overline{[\neg\neg\varphi]} = [\varphi] & \overline{[\neg(\varphi \wedge \psi)]} = [\neg\varphi \vee \neg\psi] & \overline{[\neg(\varphi \vee \psi)]} = [\neg\varphi \wedge \neg\psi] & \overline{[\neg\{f \leq c\}]} = \{f > c\} \\ \overline{[\neg\{f < c\}]} = \{f \geq c\} & \overline{[\neg\{f \geq c\}]} = \{f < c\} & \overline{[\neg\{f > c\}]} = \{f \leq c\} \end{array}$$

seven axioms — deduction rules with nothing above the line — at the spec surface, each concluding its region-denotation equality; a satisfaction judgment rewrites across any of them in either direction with certified region and rows transported verbatim, and no negation node survives to the baked representation (surviving negative literals are the typing rejection's business, not a rule's).

QN<sub>NF</sub>REWRITE is the spec-surface negation calculus (né NNFDuality): double negation, De Morgan through  $\wedge/\vee$ , and the four atom/strict swaps  $\neg\{f \leq c\} \leftrightarrow \{f > c\}$ ,  $\neg\{f < c\} \leftrightarrow \{f \geq c\}$  — both orientations of both comparison directions. The seven dualities are *axioms*: deduction rules with nothing above the line, each concluding its region-denotation equality, stated once per duality. Each licenses a judgment-level  $1 \rightarrow 1$  rewrite of a formula inside a satisfaction judgment: the rewritten formula denotes the same set of states, so any region under-approximating one denotation under-approximates the other, and the judgment transports unchanged. A producer uses the dualities to push negations down to atoms (the negation-normal-form pass of the QSTREETTREQUESTNNF section) so that every negative position is consumed either by an atom swap or by the typing pass's rejection — never by a negation node in the certificate. The checker recomputes nothing: the dualities are definitional set identities over the state space, and the strict-inequality sides interact with the closure discipline (rounding of strict literals at positive positions) only through the separate closure rules, deliberately out of this rule's scope.

There is no single target rule, and hence no *alias-for* header here: each axiom stands on its own definitional equality. Mechanization state, plainly: the bound statements below are the four atom swaps, machine-checked as set-level denotation equalities in both orientations of both comparison directions (module BernsteinLogicAux.NNFDuality: `compl_le_atom`, `compl_lt_atom`, `compl_ge_atom`, `compl_gt_atom`), together with the normalization pass's denotation-preservation theorem `denot_nnfAux`, inside which double negation and De Morgan are consumed from the ambient set library — each applied once per duality, so the displayed equalities are covered jointly by the swaps (atoms) and the pass theorem (connectives). These are definitional set identities over the state space, warranted in full; the entry carries no conditional flag.

*notes* Both orientations of both directions are stated deliberately: an early one-sided draft of the atom swaps was caught in review, and the repaired statement is the four-lemma family. The strict-atom sides are stated here as *denotation* facts only; whether a strict literal may appear in a concluded region is the closure discipline's question, answered by polarity-directed rounding in its own catalogue rows.

### Lean statement

BernsteinLogicAux.NNFDuality.`compl_le_atom`

statement bound

```
-- T12 atom swap: `¬{f ≤ c} ↔ {f > c}`. -/
theorem compl_le_atom : {x | f x ≤ c}ᶜ = {x | c < f x}
```

BernsteinLogicAux.NNFDuality.`compl_lt_atom`

statement bound

```
-- T12 atom swap: `¬{f < c} ↔ {f ≥ c}`. -/
theorem compl_lt_atom : {x | f x < c}ᶜ = {x | c ≤ f x}
```

BernsteinLogicAux.NNFDuality.`compl_ge_atom`

statement bound

```

theorem compl_gt_atom : {x | c < f x}ᶜ = {x | f x ≤ c}
```

BernsteinLogicAux.NNFDuality.`denot_nnfAux`

statement bound

```

/-- **Denotation preservation of the NNF pass, both polarities** – the T12
dualities (double negation `compl_compl`, De Morgan `Set.compl_inter`/
`Set.compl_union`) are exactly the cases of this induction; each is applied
once, which is the catalogue's "stated once as a definitional axiom per
duality" realized as proof structure. -/
theorem denot_nnfAux : ∀ (φ : Form α) (b : Bool),
  (φ.nnfAux b).denot den = if b then φ.denot den else (φ.denot den)ᶜ

```

## Correspondence (Steele display ↔ Lean)

**reviewer-certified against the displayed texts** The dictionary below is a reviewer-certified statement of how the mechanized statements above interpret the displayed rule: display metavariable  $\mapsto$  Lean binder, each display hypothesis  $\mapsto$  the premise or side condition carrying it, the display conclusion  $\mapsto$  the goal — with any deliberate difference in width between display and mechanization named outright. Certification is recorded as a hash triple over (the displayed cell, the extracted statement texts, this dictionary's own text); if any of the three changes, this block turns amber until a reviewer re-certifies. The correspondence claim itself remains editorial — reviewer-grade, not machine-checked; its machine-checked successor types each soundness statement against the rule as a structured object, and supersedes this block per rule as it lands.

The displayed atom/strict swaps map one-to-one onto the four bound equalities, each a region-denotation identity:  $\llbracket \neg\{f \leq c\} \rrbracket = \{f > c\} \mapsto \text{compl\_le\_atom} : \{x \mid f\ x \leq c\}^c = \{x \mid c < f\ x\}$ , and likewise  $\text{compl\_lt\_atom} (\neg\{f < c\} = \{f \geq c\})$ ,  $\text{compl\_ge\_atom}$ ,  $\text{compl\_gt\_atom}$  (the reversed orientations — both directions bound separately, honouring the recorded one-sidedness catch). Binder note, wider-safe:  $f : \sigma \rightarrow \mathbb{R}$  is an arbitrary function on an arbitrary carrier — the polynomial atom structure of the certificate format is erased, so the certified equalities cover every instance the rule will ever be applied to. The propositional dualities ( $\neg\neg\varphi$ , De Morgan both ways)  $\mapsto$  the neg/and/or cases of  $\text{denot\_nnfAux}$ 's both-polarity induction, where  $\text{compl\_compl}$  /  $\text{Set.compl\_inter}$  /  $\text{Set.compl\_union}$  are each consumed from `mathlib` once — the entry's “stated once per duality” realized as proof structure rather than as four more standalone statements. Width note: the entry is unconditional — set-level witnesses cover the catalogued claim in full (axioms: `propext` alone) — and the grammar-level guarantee the flavor text mentions (no negation node survives to the baked representation) is certified not here but by the `QStreettRequestNnf` entry's normal-form type; this page's statements are the denotation half only, as its note already rules.

## Lean verifier receipts

module `BernsteinLogicAux.NNFDuality`; bound build 97564f8e3950... (bound from receipt 21f04961748c0302, 2026-07-29T01:03:33Z). A receipt records that named checking layers accepted a build: (module, compiled-artifact SHA-256, environment SHA-256, checker layers), minted when the checking gate ran; the store receipts attesting the bound build are listed with the layers each run credited. Nothing here asks the reader to trust the store: every layer is an independently runnable program over the quoted sources — rebuild the module and re-run the checkers to reproduce the verdict. Receipts attesting superseded builds credit no layer and are omitted from this rendering (the count of omissions, if any, is noted below).

| receipt          | minted               | layers                             | status  |

### gate-layer coverage of the bound build:

build (lake build (elaboration)) **current**

replay (leanchecker (official kernel replay)) **current**

hardened (safe\_verify (hardened screen)) **current**

decorrelated (lean4export + nanoda (decorrelated kernel)) **current**

**comparator: none** no fixture in the three-implementation comparator harness (compiled / kernel-interpreted / reference-interpreted) exercises this rule.

## HOL4 statement

### OUT OF SCOPE BY DESIGN

Out of scope for the HOL side *by design*: the dualities are producer-side formula rewrites that unpack to definitional denotation equalities before any certificate is emitted — no wire object carries a negation node (the typing discipline rejects surviving negative literals), so there is nothing for a wire checker, HOL or otherwise, to verify. Checked against the HOL sources: the `bern_catalogue` theory is the base-calculus checker cone; formula-level negation of the extension theory's spec surface does not appear in it.

## HOL verifier receipts

### NONE

no HOL verification receipt exists for this rule.

## Proof

Genre: axioms at the spec surface (roster tier 3). The seven dualities are deduction rules with nothing above the line, each concluding a definitional region-denotation equality — there is no single target rule being respelled, and no premise to carry: the equality is the entire content. The payload-transport honesty clause of the batch is Recipe [R50.1](#) of the `QSTREETTDEGENERATE` section, and applies here vacuously (no payload ever exists to transport — the dualities are applied before emission).

**Recipe R53.1** (the seven axioms). Over a state space  $S$ , with  $\llbracket \cdot \rrbracket$  the region denotation of spec-surface formulas and  $f : S \rightarrow \mathbb{R}$  ranging over atom left-hand sides:

$$\begin{array}{llll} \overline{\llbracket \neg \neg \varphi \rrbracket} = \overline{\llbracket \varphi \rrbracket} & \overline{\llbracket \neg(\varphi \wedge \psi) \rrbracket} = \overline{\llbracket \neg \varphi \vee \neg \psi \rrbracket} & \overline{\llbracket \neg(\varphi \vee \psi) \rrbracket} = \overline{\llbracket \neg \varphi \wedge \neg \psi \rrbracket} & \overline{\llbracket \neg\{f \leq c\} \rrbracket} = \overline{\{f > c\}} \\ \overline{\llbracket \neg\{f < c\} \rrbracket} = \overline{\{f \geq c\}} & \overline{\llbracket \neg\{f \geq c\} \rrbracket} = \overline{\{f < c\}} & \overline{\llbracket \neg\{f > c\} \rrbracket} = \overline{\{f \leq c\}} \end{array}$$

Each axiom licenses a judgment-level  $1 \rightarrow 1$  rewrite in either direction: a satisfaction judgment whose formula contains one side concludes identically with the other side substituted, the certified region unchanged.

|                                          | rewritten node                                                                             | image                                                |
|------------------------------------------|--------------------------------------------------------------------------------------------|------------------------------------------------------|
| <b>Recipe R53.2</b> (payload transport). | formula (one duality applied at one position)<br>certified region, judgment kind, all rows | formula (the dual form at that position)<br>verbatim |

Unpack-function slot: no verified payload function in this edition (batch template) — and here the slot is moot by design: the typing discipline rejects surviving negative literals, so the dualities exist to be applied *before* any payload exists.

**Proposition R53.3** (soundness of the axioms — two lines each). *All seven concluded equalities hold.*

*Proof.* The propositional three are complement involution and De Morgan for sets. The atom four: pointwise over  $S$ , the negation of  $f(y) \leq c$  is  $c < f(y)$  and the negation of  $f(y) < c$  is  $c \leq f(y)$  — the total order on  $\mathbb{R}$  — and the remaining two are the same facts read in the other orientation. (Machine-checked: the four atom swaps as set-level equalities, and the propositional three consumed from the ambient set library inside the normalization pass's denotation theorem; hash-bound in this edition.)  $\square$

**Proposition R53.4** (soundness corollary). *If  $R \subseteq \llbracket \varphi \rrbracket$  and  $\varphi'$  arises from  $\varphi$  by one duality, then  $R \subseteq \llbracket \varphi' \rrbracket$ ; hence every satisfaction judgment transports across a duality unchanged, in both directions.*

*Proof.* Denotations are equal (Proposition [R53.3](#)), and substitution preserves that: region denotation is compositional — each connective's denotation is a fixed set operation on its children's — so by induction on the surrounding formula, replacing a subformula by one of equal denotation leaves every enclosing denotation unchanged. The machine-checked cousin of this one-position congruence is the normalization pass's denotation-preservation theorem, which pushes negation through *all* eligible positions in one traversal. The pass consumes the propositional facts — the complement of a conjunction or disjunction, once per constructor case — and treats atoms opaquely: a negatively-occurring atom survives as a negated literal whose denotation is the complement, and the four atom dualities are separate bound facts that swap that complement for its closed-form partner. That division realizes what the display means by “stated once per duality”: each equality is one definitional fact, cited where it is used, never re-derived.  $\square$

*Remark R53.5* (what this rule deliberately does not say). The strict-atom swaps are *denotation* facts; whether a strict inequality may appear in a concluded region atom is a different question, answered by the closure discipline (polarity-directed rounding) in its own catalogue rows. And the probability operator is absent from the display on purpose: a negated probability bound at even polarity is not rewritten but *rejected* by the typing pass — the polarity theorem of the `QSTREETTREQUESTNNF` section is what makes that rejection a surface-level check.

## Rule 54. QSTREETTREQUESTNNF (alias for QSTREETTBATTERY)

### The rule (Steele metanotation)

as realized in the mechanized development; source row: QTSL-rules.toml — *QStreettRequestNnf*. The metanotation statement is typeset by hand for notational quality; its mechanized ground truth is the Lean statement below, extracted from the sources at every build of this book and hash-bound. The rule *roster* is machine-checked (every mechanized rule tag round-trips to exactly one catalogue row); the statement *text* is editorial, checked by eye against the extracted Lean beside it.

$$\frac{\mathcal{M}, x_0 \in R \models \text{SProbGE}(p, \text{PDwellStreett}(\dots, \text{PairCmpl}(\text{elimNeg}(\text{nnf}(\rho_i)), \varphi_i), \dots))}{\mathcal{M}, x_0 \in R \models \text{SProbGE}(p, \text{PDwellStreett}(\dots, \text{PairCmpl}(\rho_i, \varphi_i), \dots))} \quad \overline{\llbracket \text{elimNeg}(\text{nnf}(\rho)) \rrbracket = \llbracket \rho \rrbracket}$$

per pair  $(\rho_i, \varphi_i)$ , applied at each cmpl-typed pair while base-typed requests pass unchanged: the request *body* is rewritten to literal normal form by the *QNNfRewrite* dualities — negation-freedom of the output holds *by construction* of the normal-form grammar (no negation node exists to build) — with the cmpl tag **RETAINED**: the complement applies at the consumption boundary (*QStreettCmplRequest*), never as a literal. The displayed axiom is the warrant: complements of equal denotations are equal, so the retained tag consumes identically. Polarity theorem: a surviving negative literal is exactly an odd-polarity atom occurrence of the input — so the neg-P rejection is a surface polarity check, stable under normalization.

QSTREETTREQUESTNNF normalizes each Streett pair into the bundle's expected input shape (né *StreettRequestNNF*): base-typed requests pass through unchanged, and a complement-typed request has its formula rewritten to negation normal form — negations pushed to the atoms by the *QNNfRewrite* rewrites — so that the complement is applied at the *consumption boundary* (the atom swaps, or the complement-request rule), never carried as a formula literal. It is an alias: the rewrite is a  $1 \rightarrow 1$  respelling of one pair inside one *QSTREETTBATTERY* node, and its warrant is denotation preservation of the normalization pass — the region the pair constrains is unchanged, so the judgment transports verbatim.

The load-bearing extra is the *polarity theorem*: the surviving negative literals of the normal form are exactly the odd-polarity atom occurrences of the input formula. Its consequence is that the typing pass's rejection of negated probability literals — which guards against smuggling a probability *upper* bound through an even number of negations — is equivalent to a surface-level polarity check on the un-normalized formula: normalization can never manufacture a rejected literal that was not already there at odd polarity, and never loses one. What would break without it: a normalization pass without the polarity invariant could present a well-typed surface whose normal form hides a rejected literal, and the consumption boundary would silently consume a bound in the wrong direction.

Mechanization state, plainly: the pass and both theorems are machine-checked structurally, and the bound statements below are their statements (module *BernsteinLogicAux.NNFDuality*): the normalizer *Form.nnf* lands in a literal normal form whose *type* has no negation node — negation-freedom by construction, the strongest form of the well-formedness claim — with denotation preservation *denot\_nnf* (the displayed  $\llbracket \text{nnf}(\rho_i) \rrbracket = \llbracket \rho_i \rrbracket$ ), the polarity theorem *negLits\_nnf* (surviving negative literals = odd-polarity atom occurrences) and its rejection face *nnf\_no\_negLit\_iff*, and the consumption-boundary elimination *denot\_elimNeg*. The rule's scope is the propositional skeleton, deliberately — the path-operator nodes of the spec surface are handled by their own ruled aliases and typing rejections, never by this pass — and the witnesses cover that scope in full, so the entry carries no conditional flag.

**notes** The pass is a reference implementation on the producer side; nothing checker-facing depends on running it. What the certificate format sees is only the normalized result, and the typing pass independently rejects any surviving negative probability literal — so a defective producer normalization can produce rejections, never unsoundness.

### Lean statement

*BernsteinLogicAux.NNFDuality*. **denot\_nnf**

statement bound

```
-- Denotation preservation of `Form.nnf` (T22's soundness face). -/
theorem denot_nnf (φ : Form α) : (φ.nnf).denot den = φ.denot den
```

*BernsteinLogicAux.NNFDuality*. **negLits\_nnf**

statement bound

```
-- **The T22 polarity theorem** ("a surviving neg-P literal is ALWAYS the
-- rejected even-polarity form", catalogue T22 – the wf theorem): the surviving
-- negative literals of the normal form are exactly the **odd-polarity** atom
-- occurrences of the input. Consequently the typing pass's neg-literal rejection
-- (`qtsl_typing/v1`, catalogue R6) is equivalent to a surface-level polarity
-- check on the un-normalized formula. -/
theorem negLits_nnf (φ : Form α) : (φ.nnf).negLits = φ.occs false
```

*BernsteinLogicAux.NNFDuality*. **nnf\_no\_negLit\_iff**

statement bound

```

/-- The rejection face of the polarity theorem: the normal form is free of
`P`-flagged negative literals iff no `P`-atom occurs at odd polarity. -/
theorem nnf_no_negLit_iff (φ : Form α) (P : α → Prop) :
  (∀ a ∈ (φ.nnf).negLits, ¬ P a) ↔ ∀ a ∈ φ.occs false, ¬ P a

```

BernsteinLogicAux.NNFDuality.denot\_elimNeg

statement bound

```

/-- **Denotation preservation of dual-atom elimination**: where each dual atom
denotes the complement (`hd` – the per-duality definitional axioms, e.g. the
`compl_le_atom` family above), elimination preserves the region. This is the
lawfulness of consuming a `cmpl`-typed request through swapped atoms
(atom-level complement elimination's atom step, the T9b input shape). -/
theorem denot_elimNeg {σ : Type*} (den : α → Set σ) (d : α → α)
  (hd : ∀ a, den (d a) = (den a)c) :
  ∀ φ : NForm α, (φ.elimNeg d).denot den = φ.denot den

```

## Correspondence (Steele display ↔ Lean)

**reviewer-certified against the displayed texts** The dictionary below is a reviewer-certified statement of how the mechanized statements above interpret the displayed rule: display metavariable  $\mapsto$  Lean binder, each display hypothesis  $\mapsto$  the premise or side condition carrying it, the display conclusion  $\mapsto$  the goal — with any deliberate difference in width between display and mechanization named outright. Certification is recorded as a hash triple over (the displayed cell, the extracted statement texts, this dictionary's own text); if any of the three changes, this block turns amber until a reviewer re-certifies. The correspondence claim itself remains editorial — reviewer-grade, not machine-checked; its machine-checked successor types each soundness statement against the rule as a structured object, and supersedes this block per rule as it lands.

The flavor text's “negation-freedom holds by construction of the normal-form grammar” is certified *by type*: the target grammar `NForm` (positive/negative literals under  $\wedge/\vee$ ) has no negation constructor, so no theorem about negation-freedom exists to state — the inductive definition is the certificate. The displayed constituents — the judgment-transport rule and its warranting axiom — map onto the four bound statements:

- $\llbracket \text{elimNeg}(\text{nnf}(\rho_i)) \rrbracket = \llbracket \rho_i \rrbracket \mapsto$  the composition of `denot_nnf` ( $(\phi.\text{nnf}).\text{denot den} = \phi.\text{denot den}$  — the normalizer preserves the region, `QNnfRewrite`'s dualities consumed as the induction) with `denot_elimNeg`, whose hypothesis `hd : ∀ a, den (d a) = (den a)c` is the per-duality definitional-axiom pack: elimination is lawful exactly where a dual atom exists, which is the flavor text's “the complement applies at the consumption boundary, never as a literal” — the retained `cmpl` tag consumes at `QStreettCmplRequest` through this same lemma, and dropping the tag would change the pair's truth value (a one-state counterexample witnesses it), which is why the rewrite retains it.
- the polarity theorem  $\mapsto$  `negLits_nnf : (φ.nnf).negLits = φ.occs false` — surviving negative literals are *exactly* the odd-polarity atom occurrences — with the rejection face `nnf_no_negLit_iff` certifying the flavor text's “the neg-P rejection is a surface polarity check, stable under normalization.”

Width note: atoms and denotations are fully abstract  $(\alpha, \text{den} : \alpha \rightarrow \text{Set } \sigma)$  — the per-pair Streett context, the base-typed-request pass-through, and the probability flavour of the neg-P check are all consumers of these statements, not content of them; unconditional, `propext` alone, set-level witnesses covering the catalogued claim in full.

## Lean verifier receipts

module BernsteinLogicAux.NNFDuality; bound build 97564f8e3950... (bound from receipt 21f04961748c0302, 2026-07-29T01:03:33Z). A receipt records that named checking layers accepted a build: (module, compiled-artifact SHA-256, environment SHA-256, checker layers), minted when the checking gate ran; the store receipts attesting the bound build are listed with the layers each run credited. Nothing here asks the reader to trust the store: every layer is an independently runnable program over the quoted sources — rebuild the module and re-run the checkers to reproduce the verdict. Receipts attesting superseded builds credit no layer and are omitted from this rendering (the count of omissions, if any, is noted below).

## HOL4 statement

### OUT OF SCOPE BY DESIGN

Out of scope for the HOL side *by design*: the normalization is a producer-side rewrite completed before emission — certificates carry only its output, and the output's well-formedness is enforced by the typing pass, not by a checker replay of the rewrite. No wire object exists for a HOL statement to be about. Checked against the HOL sources: the `bern_catalogue` theory carries no spec-surface formula grammar.

## HOL verifier receipts

### NONE

no HOL verification receipt exists for this rule.

## Proof

Genre: alias rule (tier 3) — a respelling template; the batch's shared template is Recipe [R50.1](#) of the `QSTRETTDEGENERATE` section.

**Recipe R54.1** (the filled-in application — one pair, normalized). Fix a Streett pair  $(\rho, \varphi)$  inside a `QSTRETTBATTERY` node, with  $\rho$  complement-typed. Write `nnf` for the negation-normal-form pass on the propositional skeleton (atoms,  $\neg$ ,  $\wedge$ ,  $\vee$ ): negations pushed inward by the `QNNFREWITE` rewrites until only literals remain. The rewrite is

$$(\text{cmpl } \rho, \varphi) \rightsquigarrow (\text{cmpl } (\text{elimNeg}(\text{nnf}(\rho))), \varphi)$$

— the body normalized, the complement tag *retained*: per the source discipline the complement applies at the consumption boundary (the complement-request rule), never as a literal. After the rewrite every literal of the request body is positive (atom-swapped where it was negative), and the pair is in exactly the input shape the bundle and the complement-request rule expect. A base-typed pair is already in that shape: on it the rewrite is the identity, the transport trivial, and the exactness identity reflexivity — stated once here so the corollary's case split below is complete. One pair to one pair, inside one node: the alias shape.

| Recipe R54.2 (payload transport).       |                                                                                                |
|-----------------------------------------|------------------------------------------------------------------------------------------------|
| un-normalized pair                      | normalized pair                                                                                |
| request body $\rho$ (cmpl tag retained) | <code>elimNeg(nnf(<math>\rho</math>))</code> , negative literals eliminated through dual atoms |
| response formula, certificates, rows    | verbatim                                                                                       |
| polarity bookkeeping                    | the polarity theorem (Proposition <a href="#">R54.4</a> ); nothing stored                      |

Unpack-function slot: no verified payload function in this edition (batch template); the structural mechanization exists (the normalizer and its theorems, named below; the four theorems hash-bound in this edition).

**Proposition R54.3** (the exactness identity — denotation preservation).  $\llbracket \text{nnf}(\rho) \rrbracket = \llbracket \rho \rrbracket$ , and eliminating negative literals through dual atoms preserves the denotation.

*Proof.* Induction on  $\rho$ , with the `QNNFREWITE` equalities as the cases — double negation and De Morgan drive the recursion, the atom swaps close the leaves. The elimination step substitutes, for each negative literal, the dual atom denoting the complement; equality is preserved literal by literal. (Machine-checked: `denot_nnf` and `denot_elimNeg`, hash-bound in this edition; the eliminated form has no negative literals at all, `negLits_elimNeg` — an unpinned auxiliary of the same module.) Complements of equal sets are equal, so the retained `cmpl` tag's consumption-boundary denotation  $S \setminus \llbracket \rho \rrbracket$  is preserved as well — the rewrite itself never discharges the complement.  $\square$

**Proposition R54.4** (the polarity theorem). *The surviving negative literals of  $\text{nnf}(\rho)$  are exactly the atom occurrences of  $\rho$  at odd polarity (an odd number of enclosing negations). Consequently the normal form is free of negated occurrences of a given atom class if and only if the input has no odd-polarity occurrence of that class.*

*Proof.* Strengthen to the polarity-indexed pass (normalizing  $\rho$  or  $\neg\rho$  according to a polarity bit) and induct: at an atom the bit decides the literal's sign; at a negation the bit flips; at  $\wedge$  and  $\vee$  the bit distributes (De Morgan swapping the connective when negative). The negative-literal set on one side and the odd-polarity occurrence set on the other satisfy the same recursion. The rejection face is a rewrite of the same equality. (Machine-checked: `negLits_nnf`, via the unpinned auxiliary `negLits_nnfAux`, and `nnf_no_negLit_iff`; both theorems hash-bound in this edition. Terminology, once: a *negative literal* is a signed-literal constructor

of the normal-form grammar, not an occurrence of the formula negation node — the grammar carries literals of both signs and no negation constructor, which is the sense in which negation-freedom of the output holds by *type*; the elimination pass then removes the negative-signed literals through dual atoms.)  $\square$

**Proposition R54.5** (soundness corollary). *A bundle node whose pair is normalized concludes identically to the un-normalized node: through QSTRETTBATTERY directly for base-typed requests, and through the QSTRETTCMPLREQUEST weakening for the consumed complement — with Proposition R54.3 guaranteeing both nodes constrain the same regions.*

*Proof.* Immediate from Proposition R54.3 and the target rules' theorems, each at its own proven scope — the rewrite itself is propositional and profile-free; whatever conditional mark the concluding bundle or weakening node carries is inherited there, not here; the alias adds no semantic content of its own.  $\square$

*Remark R54.6* (what the polarity theorem is protecting). The typing discipline rejects probability-atom occurrences at odd polarity — an odd number of enclosing negations, whether worn as a bare negated literal in even context or as a positive literal under an odd stack — because a negated lower bound is an upper bound, and the certificate calculus deliberately has no rule concluding probability upper bounds through this pass. The theorem makes the rejection *stable under normalization*: no sequence of dualities can manufacture or hide a rejected literal, so the check may run on the surface formula once, before normalization, with the same verdict. A guard that had to chase literals through rewrites would be a moving target; a polarity count is not.

| proof step                           | formal anchor                                                                                                           |
|--------------------------------------|-------------------------------------------------------------------------------------------------------------------------|
| normalizer, negation-freedom by type | Form.nnf, NForm (BernsteinLogicAux.NNFDuality; definitions — no statement pins, their theorems below carry the warrant) |
| Proposition R54.3                    | denot_nnf, denot_elimNeg (same module, hash-bound); negLits_elimNeg (unpinned auxiliary)                                |
| Proposition R54.4                    | negLits_nnf, nnf_no_negLit_iff (same module, hash-bound)                                                                |
| Proposition R54.5 targets            | the QSTRETTBATTERY and QSTRETTCMPLREQUEST sections                                                                      |

## Rule 55. QAVOID (alias rule)

### The rule (Steele metanotation)

as realized in the mechanized development; source row: `QTSL-rules.toml` — `QAvoid`. The metanotation statement is typeset by hand for notational quality; its mechanized ground truth is the Lean statement below, extracted from the sources at every build of this book and hash-bound. The rule *roster* is machine-checked (every mechanized rule tag round-trips to exactly one catalogue row); the statement *text* is editorial, checked by eye against the extracted Lean beside it.

$$\frac{\mathcal{M}, x_0 \in R \models \text{SProbGE}(p, \text{PAlways}(\text{SNot } \beta))}{\mathcal{M}, x_0 \in R \models \text{P}_{\geq p}[\text{avoid } \beta]}$$

$\text{avoid } \beta := G\neg\beta$  — the unfolding is the rule (the premise is the target judgment at the expansion), so the alias is sound by definition: the equation is definitional at the set level (`rfl`-grade), and the negation atom is ruled in by the `QNNFREWRITE` swaps. The surface constructor builds its expansion rather than a new node kind — witnessed by the producer-side concrete-syntax canonicity battery; no rule sort exists and none is needed.

`QAVOID` is the avoidance sugar of the spec surface:  $\text{avoid } \beta := G\neg\beta$  — avoidance is safety of the negation, exact, the negation being ruled in by the `QNNFREWRITE` atom swaps. An alias unpacking to *one* application of an existing rule (the safety battery at the avoid set), and the strongest-fidelity member of the sugar trio (its siblings: `QSTREETTGF`, `QSTREETTFG`): the identity the definition rides is machine-checked as a path-event identity in the target rule's concluded shape (module `BernsteinLogicAux.QtslAliases`), `sugarAvoid_denot`, proof `rfl`, axiom-free — definitional exactness, certified as such by the kernel. A producer, and a reader of specifications, may use the sugar constructor freely: it builds its expansion rather than a new node kind, so nothing downstream — typing, compilation, checking — ever sees a sugar node, and no checker recomputation exists for this rule at all. There is no soundness lemma here because the equation is a definition; the witness that the surface really does build the expansion remains the reference implementation's concrete-syntax canonicity test battery — an implementation property, not a semantic claim, so it says a test rather than a theorem. No profile enters; the entry carries no conditional flag.

**notes** The avoid sugar is also the compatibility layer to plain safety specification: avoidance properties state directly against the safety kernel with no automaton machinery, which is the degenerate (and most common) case of the classical-surface translation the trio provides.

### Lean statement

`BernsteinLogicAux.QtslAliases.sugarAvoid_denot`

statement bound

```
/-- **`SugarBatch` (T10), first sugar**: `avoid β := G ¬β` — avoidance is
safety of the negation, definitionally (the proof is `rfl`; the negation is
ruled in by the `NNFDuality.lean` atom swaps (rule `QnnfRewrite`)). Exact: no direction is lost. -/
theorem sugarAvoid_denot {S : Type*} (B : Set S) :
  {ω : ℕ → S | ∀ n, ω n ∉ B} = {ω : ℕ → S | ∀ n, ω n ∈ Bc}
```

### Correspondence (Steele display ↔ Lean)

**reviewer-certified against the displayed texts** The dictionary below is a reviewer-certified statement of how the mechanized statements above interpret the displayed rule: display metavariable  $\mapsto$  Lean binder, each display hypothesis  $\mapsto$  the premise or side condition carrying it, the display conclusion  $\mapsto$  the goal — with any deliberate difference in width between display and mechanization named outright. Certification is recorded as a hash triple over (the displayed cell, the extracted statement texts, this dictionary's own text); if any of the three changes, this block turns amber until a reviewer re-certifies. The correspondence claim itself remains editorial — reviewer-grade, not machine-checked; its machine-checked successor types each soundness statement against the rule as a structured object, and supersedes this block per rule as it lands.

The displayed rule transports the target judgment across the defining equation  $\text{avoid } \beta := G\neg\beta$  (premise: the expansion's judgment; conclusion: the sugared form). `sugarAvoid_denot` certifies that equation and is `rfl` — definitional at the set level, the strongest possible fidelity, with the negation-atom step ruled in by the `QNNFREWRITE` swaps as the docstring notes. Width note: a per-path equivalence over arbitrary state types — no measure enters, so the identity transports under every profile's path measure by congruence; the remaining accompanying claim (the entry's flavor text: the certificate surface *builds* the expansion rather than minting a node kind) is a property of the concrete-syntax canonicity battery — a test, not a theorem, deliberately outside this bound set, exactly as the roster witness says.

### Lean verifier receipts

module `BernsteinLogicAux.QtslAliases`; bound build 570599779c29... (bound from receipt 5a60f4d01fd81ac5, 2026-07-21T05:39:02Z). A receipt records that named checking layers accepted a build: (module, compiled-artifact SHA-256, environment SHA-256, checker layers), minted when

the checking gate ran; the store receipts attesting the bound build are listed with the layers each run credited. Nothing here asks the reader to trust the store: every layer is an independently runnable program over the quoted sources — rebuild the module and re-run the checkers to reproduce the verdict. **comparator:** none no fixture in the three-implementation comparator harness (compiled / kernel-interpreted / reference-interpreted) exercises this rule.

## HOL4 statement

### OUT OF SCOPE BY DESIGN

Out of scope for the HOL side *by design*, in the strongest form an alias can have: the sugar is a definitional constructor that builds its expansion at the surface — no sugar node exists in any representation downstream of parsing, wire format included, so there is no artefact for any checker port to be about. Checked against the HOL sources: the `bern_catalogue` theory carries no spec-surface grammar.

## HOL verifier receipts

### NONE

no HOL verification receipt exists for this rule.

## Proof

Genre: alias rule (tier 3) — a respelling template; the shared template is Recipe [R50.1](#) of the `QSTREETTDEGENERATE` section. This rule is the degenerate case of even that template: the `unpack` is a *definition*, so the five artefacts collapse to the definitional equation, its reading, and the target section.

**Recipe R55.1** (the filled-in application).

$$\text{avoid } \beta := G\neg\beta$$

The concluding judgment discharges through one existing rule: avoidance through the safety battery (`QSAFETYBATTERY`) at the `avoid` set  $\llbracket \beta \rrbracket$ , with  $\neg\beta$  read by the semantic negation clause  $\llbracket \neg\beta \rrbracket = S \setminus \llbracket \beta \rrbracket$  (the `QNNFREWITE` atom dualities supply the syntactic normal form — the atom swap alone when  $\beta$  is an atom, De Morgan propagation when it is compound).

**Recipe R55.2** (payload transport). The expansion  $G\neg\beta$  carries the safety kit at  $U := \llbracket \beta \rrbracket$ , verbatim. No `unpack` function is owed here, because none will ever exist: the constructor *is* its expansion, so there is no sugar payload to transport from — the strongest possible form of producers-elaborate-before-emission.

**Proposition R55.3** (the exactness identity). *A path always avoids  $\llbracket \beta \rrbracket$  iff it always satisfies  $\neg\beta$  — definitional, by the negation clause  $\llbracket \neg\beta \rrbracket = S \setminus \llbracket \beta \rrbracket$ , with `QNNFREWITE` normalizing the syntax where needed.*

*Proof.* Definitional (the bound Lean identity is `rfl`, axiom-free — the kernel certifies the two sides as one term). □

**Proposition R55.4** (soundness corollary). *The sugared judgment is concluded by the target rule's theorem, with no additional obligation: the sugar constructor builds the expansion, so the sugared judgment is the target judgment.*

*Proof.* Definitional unfolding plus the target section's theorem. The witness that the surface implementation honours the definition — that the constructor builds its expansion rather than introducing a new node kind — is the reference implementation's concrete-syntax canonicity test battery; no checker-facing artefact depends on it, since no downstream representation contains a sugar node. □

## Rule 56. QSTREETTGF (alias rule)

### The rule (Steele metanotation)

as realized in the mechanized development; source row: QTSL-rules.toml — *QStreettGF*. The metanotation statement is typeset by hand for notational quality; its mechanized ground truth is the Lean statement below, extracted from the sources at every build of this book and hash-bound. The rule *roster* is machine-checked (every mechanized rule tag round-trips to exactly one catalogue row); the statement *text* is editorial, checked by eye against the extracted Lean beside it.

$$\frac{\mathcal{M}, x_0 \in R \models \text{SProbGE}(p, \text{PDwellStreett}(\text{PairBase}(\text{STrue}, \varphi))) \quad \text{paths total over the state space}}{\mathcal{M}, x_0 \in R \models \text{SProbGE}(p, \text{GF } \varphi)}$$

$\text{GF}\varphi := \text{Streett}((\top, \varphi))$  — recurrence is the one-pair Streett condition at the trivially-true request, *QSTREETTDEGENERATE*'s concluded shape, so the sugar lands on that rule's bound statement without adjustment. The totality premise is the bound chart, exactly the certified statement's scope. Killed-process classes are the named unbound residue: the identity extends whenever the cemetery is adjoined inside the region vocabulary *and* killed paths are continued as total paths at  $\dagger$  ( $\top = V \cup \{\dagger\}$ ) — that  $\dagger$ -extended restatement is not yet part of the certified semantics, so it stays here rather than in a premise; with the cemetery outside the region vocabulary the rewrite direction over-claims, and that class is kept closed by the batteries' full-mass gates. The surface constructor builds its expansion rather than a new node kind — witnessed by the producer-side concrete-syntax canonicity battery; no rule sort exists and none is needed.

*QSTREETTGF* is the recurrence sugar of the spec surface:  $\text{GF}\varphi := \text{Streett}((\top, \varphi))$  — recurrence is the degenerate Streett pair, the *QSTREETTDEGENERATE* section's concluded shape, so the sugar lands on that rule's bound statement without adjustment. An alias unpacking to *one* application of an existing rule; with its persistence twin *QSTREETTFG* it is the compatibility layer to the classical temporal-logic surface — GF/FG specifications translate to the Streett-primitive kernel without automaton products, the practical payoff of Büchi acceptance being a one-pair Streett condition. The identity the definition rides is machine-checked (module *BernsteinLogicAux.QtslAliases*): *sugarGF\_denot* — the per-pair Streett event at the trivially-true request *is* the recurrence event.

Scope, stated in the open because this member alone has one: the mechanized identity lives on the total path type, so it consumes the no-cemetery chart — exact on total-path state spaces and on killed-process classes with the cemetery adjoined inside the region vocabulary ( $\top = V \cup \{\dagger\}$ ); with the cemetery outside the region vocabulary the rewrite direction over-claims, and that class is kept closed by the batteries' full-mass gates. The named repair (the entry's residue): restate the identity on the  $\dagger$ -extended state type, matching the promotion lemma. The surface constructor builds its expansion rather than a new node kind; the witness for that remains the reference implementation's concrete-syntax canonicity test battery — an implementation property, a test rather than a theorem.

**notes** Why the factoring put the honesty here: as a batch row, one *PROVEN* badge covered three warrants of different semantic depths — *rfl-grade*, *chart-consuming*, and *pure-logic* — and the *chart-consuming* member's scope restriction was a memo-level footnote. As its own row it is display-level text: the exactness chart is part of what this rule *says*.

### Lean statement

*BernsteinLogicAux.QtslAliases* . **sugarGF\_denot**

statement bound

```
/-- **`SugarBatch` (T10), second sugar**: `GF φ := Streett((⊤, φ))` — the
per-pair Streett event at the trivially-true request (every state requests,
and along `atTop` over `N` the request is frequent) *is* the recurrence
event. The expansion's target is `QStreettDegenerate` (T9a), whose bound
statement `sound_QStreettDegenerate` concludes exactly the right-hand
event. -/
theorem sugarGF_denot {S : Type*} (G : Set S) (ω : ℕ → S) :
  ((∃! n in atTop, ω n ∈ (Set.univ : Set S)) → ∃! n in atTop, ω n ∈ G)
  ↔ ∃! n in atTop, ω n ∈ G
```

### Correspondence (Steele display ↔ Lean)

**reviewer-certified against the displayed texts** The dictionary below is a reviewer-certified statement of how the mechanized statements above interpret the displayed rule: display metavariable  $\mapsto$  Lean binder, each display hypothesis  $\mapsto$  the premise or side condition carrying it, the display conclusion  $\mapsto$  the goal — with any deliberate difference in width between display and mechanization named outright. Certification is recorded as a hash triple over (the displayed cell, the extracted statement texts, this dictionary's own text); if any of the three changes, this block turns amber until a reviewer re-certifies. The correspondence claim itself remains editorial — reviewer-grade, not machine-checked; its machine-checked successor types each soundness statement against the rule as a structured object, and supersedes this block per rule as it lands.

$\text{sugarGF\_denot}(\text{GF}\varphi := \text{Streett}((\top, \varphi)))$  certifies the pair event at request  $\text{Set.univ} \leftrightarrow$  the bare recurrence event — exactly  $\text{sound\_QStreettDegenerate}$ 's concluded form, so the sugar lands on  $\text{QStreettDegenerate}$ 's bound statement without adjustment. Fidelity caveat, bound honestly: the Lean statement lives on the total path type, which IS the displayed rule's totality premise (“paths total over the state space”) — the premise and the bound scope now coincide exactly. The flavor text's  $\dagger$ -extended case (cemetery adjoined inside the vocabulary with killed paths continued as total paths at  $\dagger$ : exact; cemetery outside: the rewrite over-claims) is the named unbound residue the bound statement does not and cannot witness; it is carried by the roster note's residue line, and the  $\dagger$ -extended restatement named there would move it into this bound set. No measure enters; the identity transports under every profile's path measure by congruence. The builds-expansions claim rides the canonicity battery, deliberately outside this bound set, exactly as the roster witness says.

## Lean verifier receipts

module BernsteinLogicAux.QtslAliases; bound build 570599779c29... (bound from receipt 5a60f4d01fd81ac5, 2026-07-21T05:39:02Z). A receipt records that named checking layers accepted a build: (module, compiled-artifact SHA-256, environment SHA-256, checker layers), minted when the checking gate ran; the store receipts attesting the bound build are listed with the layers each run credited. Nothing here asks the reader to trust the store: every layer is an independently runnable program over the quoted sources — rebuild the module and re-run the checkers to reproduce the verdict. Receipts attesting superseded builds credit no layer and are omitted from this rendering (the count of omissions, if any, is noted below).

| receipt          | minted               | layers                             | status  |
|------------------|----------------------|------------------------------------|---------|
| 0a3819a978e31127 | 2026-07-21T04:51:36Z | build+decorrelated                 | current |
| 0bb1074df705d863 | 2026-07-21T05:21:58Z | build+decorrelated                 | current |
| 5a60f4d01fd81ac5 | 2026-07-21T05:39:02Z | build+replay+hardened+decorrelated | current |

11 further receipt(s) in the store attest superseded builds of this module and are omitted from this rendering.

### gate-layer coverage of the bound build:

build (lake build (elaboration)) current  
 replay (leanchecker (official kernel replay)) current  
 hardened (safe\_verify (hardened screen)) current  
 decorrelated (lean4export + nanoda (decorrelated kernel)) current

comparator: none no fixture in the three-implementation comparator harness (compiled / kernel-interpreted / reference-interpreted) exercises this rule.

## HOL4 statement

### OUT OF SCOPE BY DESIGN

Out of scope for the HOL side *by design*: the sugar is a definitional constructor that builds its expansion at the surface — no sugar node exists in any representation downstream of parsing, wire format included, so there is no artefact for any checker port to be about. Checked against the HOL sources: the `bern_catalogue` theory carries no spec-surface grammar. (The chart restriction is a property of the Lean statement's ambient path type, not of any wire artefact — there is nothing HOL-side for it to attach to.)

## HOL verifier receipts

### NONE

no HOL verification receipt exists for this rule.

## Proof

Genre: alias rule (tier 3) — a respelling template; the shared template is Recipe [R50.1](#) of the `QStreettDegenerate` section. The unpack is a *definition*, so the five artefacts collapse to the definitional equation, its reading, its exactness chart, and the target section.

**Recipe R56.1** (the filled-in application).

$$\text{GF}\varphi := \text{Streett}((\top, \varphi))$$

The concluding judgment discharges through one existing rule: recurrence through the degenerate bundle (`QStreettDegenerate`).

**Recipe R56.2** (payload transport). The expansion  $\text{Streett}((\top, \varphi))$  carries the degenerate kit, verbatim. No unpack function is owed here, because none will ever exist: the constructor *is* its expansion, so there is no sugar payload to transport from — the strongest possible form of producers-elaborate-before-emission.

**Proposition R56.3** (the exactness identity, and its chart). *The pair  $(\top, \varphi)$  holds iff  $\varphi$ -states occur infinitely often (the degeneration identity, proved as the exactness identity, Proposition R50.4, of the QSTREETTDEGENERATE section). As mechanized, the identity is stated on the total path type; it therefore holds on total-path state spaces, and on killed-process classes whenever the cemetery is adjoined inside the region vocabulary  $(\top = V \cup \{\dagger\})$ . With the cemetery outside the region vocabulary the rewrite direction over-claims — a killed path visits no state cofinally, yet the vocabulary cannot say so — and that class is kept closed by the batteries' full-mass gates. The named repair is to restate the identity on the  $\dagger$ -extended state type, matching the promotion lemma; until then the chart restriction is carried in the rule's own display, in the open.*

*Proof.* The identity: by the degeneration argument of the target section, mechanized as the bound Lean statement. The chart restriction: read off the bound statement's ambient path type, as displayed.  $\square$

**Proposition R56.4** (soundness corollary). *On the stated chart, the sugared judgment is concluded by the target rule's theorem, with no additional obligation: the sugar constructor builds the expansion, so the sugared judgment is the target judgment.*

*Proof.* Definitional unfolding plus the target section's theorem, on the chart of Proposition R56.3. The witness that the surface implementation honours the definition — that the constructor builds its expansion rather than introducing a new node kind — is the reference implementation's concrete-syntax canonicity test battery; no checker-facing artefact depends on it, since no downstream representation contains a sugar node.  $\square$

| proof step                   | formal anchor                                                                                                     |
|------------------------------|-------------------------------------------------------------------------------------------------------------------|
| target                       | the QSTREETTDEGENERATE section (degeneration identity proved there)                                               |
| the identity, event-level    | sugarGF_denot (bound in the entry; total path type = the chart)                                                   |
| the chart's named repair     | the $\dagger$ -extended restatement, $\top = V \cup \{\dagger\}$ (the promotion lemma's form)                     |
| twin                         | QSTREETTFG (the safety-polarized half; consumes no chart)                                                         |
| constructor builds expansion | the reference implementation's concrete-syntax canonicity battery (documentary; no wire artefact exists to check) |

## Rule 57. QSTREETFG (alias rule)

### The rule (Steele metanotation)

as realized in the mechanized development; source row: QTSL-rules.toml — *QStreetFG*. The metanotation statement is typeset by hand for notational quality; its mechanized ground truth is the Lean statement below, extracted from the sources at every build of this book and hash-bound. The rule *roster* is machine-checked (every mechanized rule tag round-trips to exactly one catalogue row); the statement *text* is editorial, checked by eye against the extracted Lean beside it.

$$\frac{\mathcal{M}, x_0 \in R \models \text{SProbGE}(p, \text{PDwellStreett}(\text{PairBase}(\beta, \text{SFalse})))}{\mathcal{M}, x_0 \in R \models \text{SProbGE}(p, \text{FG } \neg\beta)}$$

$\text{FG}\neg\beta := \text{Streett}((\beta, \perp))$  — eventual permanent avoidance is the one-pair Streett condition that forbids infinitely many  $\beta$ -visits: with an unsatisfiable response, the pair condition says exactly that  $\beta$ -states occur only finitely often. Pure per-path logic — the safety-polarized half of the recurrence/persistence pair, consuming no conservativity. The rule's honest scope is this polarized form (FG applied to  $\neg\beta$ ): general persistence  $\text{FG}\varphi$  is not this rule. The surface constructor builds its expansion rather than a new node kind — witnessed by the producer-side concrete-syntax canonicity battery; no rule sort exists and none is needed.

QSTREETFG is the persistence-of-avoidance sugar of the spec surface:  $\text{FG}\neg\beta := \text{Streett}((\beta, \perp))$  — eventual permanent avoidance is the one-pair Streett condition that forbids infinitely many  $\beta$ -visits: with an unsatisfiable response, the pair condition says exactly that  $\beta$ -states occur only finitely often. An alias unpacking to *one* application of an existing rule (one QSTREETBATTERY node at the pair  $(\beta, \perp)$ ); the safety-polarized half of the recurrence/persistence pair — its twin is QSTREETGF, and the two land at different points of the same Streett rule. The honest scope is the polarized form (FG applied to  $\neg\beta$ ): general persistence  $\text{FG}\varphi$  is not this rule. The identity the definition rides is machine-checked (module BernsteinLogicAux.QtslAliases): *sugarFG\_denot* — the per-pair Streett event at an unsatisfiable response is eventual permanent avoidance, the finitely-often reading; pure per-path logic, no conservativity and no chart hypothesis consumed. The surface constructor builds its expansion rather than a new node kind; the witness for that remains the reference implementation's concrete-syntax canonicity test battery — an implementation property, a test rather than a theorem. No profile enters; the entry carries no conditional flag.

**notes** The two dual sugars land at different points of the same rule:  $\text{GF}\varphi$  requests always and so erases the request machinery, while  $\text{FG}\neg\beta$  makes  $\beta$  itself the request and forbids response — the ranking certificate must then pay out at every  $\beta$ -visit with nothing ever refunding it, which is exactly a proof that  $\beta$ -visits are finitely many. That both directions are single nodes of one rule — where automaton-primitive designs pay a product construction for one of them — is the practical content of the Streett-primitive choice.

### Lean statement

BernsteinLogicAux.QtslAliases . **sugarFG\_denot**

statement bound

```
/-- **`SugarBatch` (T10), third sugar**: `FG ¬β := Streett((β, ⊥))` — the
per-pair Streett event at an unsatisfiable response says the request region
is visited at most finitely often, which over `N` *is* eventual permanent
avoidance. The pair condition forbids infinitely many `β`-visits: with
response `⊥`, "infinitely often `β` implies infinitely often `False`" is
exactly "eventually always `¬β`". -/
theorem sugarFG_denot {S : Type*} (B : Set S) (ω : ℕ → S) :
  ((∃f n in atTop, ω n ∈ B) → ∃f n in atTop, ω n ∈ (∅ : Set S))
  ↔ ∀f n in atTop, ω n ∉ B
```

### Correspondence (Steele display ↔ Lean)

**reviewer-certified against the displayed texts** The dictionary below is a reviewer-certified statement of how the mechanized statements above interpret the displayed rule: display metavariable  $\mapsto$  Lean binder, each display hypothesis  $\mapsto$  the premise or side condition carrying it, the display conclusion  $\mapsto$  the goal — with any deliberate difference in width between display and mechanization named outright. Certification is recorded as a hash triple over (the displayed cell, the extracted statement texts, this dictionary's own text); if any of the three changes, this block turns amber until a reviewer re-certifies. The correspondence claim itself remains editorial — reviewer-grade, not machine-checked; its machine-checked successor types each soundness statement against the rule as a structured object, and supersedes this block per rule as it lands.

*sugarFG\_denot* ( $\text{FG}\neg\beta := \text{Streett}((\beta, \perp))$ ) certifies the pair event at response  $\emptyset \leftrightarrow$  eventual permanent avoidance ( $\forall^*$ ), the finitely-often reading — stated, like its siblings, in the target rule's concluded shape, which is what makes it consumable as a rewrite rather than a mere fact. Width note: a per-path equivalence over arbitrary state types — no measure enters, so the identity transports under every profile's path measure by congruence; the remaining accompanying claim (the entry's flavor text: the certificate surface *builds* the expansion rather than minting a node kind) is a property of the concrete-syntax canonicity battery — a test, not a theorem, deliberately outside this bound set, exactly as the roster witness says.

## Lean verifier receipts

module BernsteinLogicAux.QtslAliases; bound build 570599779c29... (bound from receipt 5a60f4d01fd81ac5, 2026-07-21T05:39:02Z). A receipt records that named checking layers accepted a build: (module, compiled-artifact SHA-256, environment SHA-256, checker layers), minted when the checking gate ran; the store receipts attesting the bound build are listed with the layers each run credited. hardened (safe\_verify (hardened screen)) current

decorrelated (lean4export + nanoda (decorrelated kernel)) current

comparator: none no fixture in the three-implementation comparator harness (compiled / kernel-interpreted / reference-interpreted) exercises this rule.

## HOL4 statement

### OUT OF SCOPE BY DESIGN

Out of scope for the HOL side *by design*: the sugar is a definitional constructor that builds its expansion at the surface — no sugar node exists in any representation downstream of parsing, wire format included, so there is no artefact for any checker port to be about. Checked against the HOL sources: the `bern_catalogue` theory carries no spec-surface grammar.

## HOL verifier receipts

### NONE

no HOL verification receipt exists for this rule.

## Proof

Genre: alias rule (tier 3) — a respelling template; the shared template is Recipe **R50.1** of the `QSTREETTDEGENERATE` section. The unpack is a *definition*, so the five artefacts collapse to the definitional equation, its reading, and the target section.

**Recipe R57.1** (the filled-in application).

$$\text{FG}\neg\beta := \text{Streett}((\beta, \perp))$$

The concluding judgment discharges through one existing rule: eventual permanent avoidance through one `QSTREETTBATTERY` node at the pair  $(\beta, \perp)$ . The honest scope is this polarized form (FG applied to  $\neg\beta$ ): general persistence  $\text{FG}\varphi$  is not this rule.

**Recipe R57.2** (payload transport). The expansion  $\text{Streett}((\beta, \perp))$  carries one bundle pair: requests  $\llbracket\beta\rrbracket$ , response empty. No unpack function is owed here, because none will ever exist: the constructor *is* its expansion, so there is no sugar payload to transport from — the strongest possible form of producers-elaborate-before-emission.

**Proposition R57.3** (the exactness identity). *The pair  $(\beta, \perp)$  holds iff  $\beta$ -states occur only finitely often, i.e. iff eventually the path permanently satisfies  $\neg\beta$ :*

$$((\exists^\infty n, \omega_n \in \llbracket\beta\rrbracket) \Rightarrow (\exists^\infty n, \omega_n \in \emptyset)) \iff \neg(\exists^\infty n, \omega_n \in \llbracket\beta\rrbracket),$$

since the consequent is false outright — two lines: an implication into falsehood is the negation of its hypothesis, and finitely many  $\beta$ -visits along a discrete path is precisely a tail of  $\neg\beta$ -states. Pure per-path logic; no conservativity and no chart hypothesis is consumed.

*Proof.* As displayed; the two lines are shown. □

**Proposition R57.4** (soundness corollary). *The sugared judgment is concluded by the target rule's theorem, with no additional obligation: the sugar constructor builds the expansion, so the sugared judgment is the target judgment.*

*Proof.* Definitional unfolding plus the target section's theorem. The witness that the surface implementation honours the definition — that the constructor builds its expansion rather than introducing a new node kind — is the reference implementation's concrete-syntax canonicity test battery; no checker-facing artefact depends on it, since no downstream representation contains a sugar node.  $\square$

*Remark R57.5* (why FG costs a bundle and GF costs only its degenerate case). The two dual sugars land at different points of the same rule.  $\text{GF}\varphi$  (the twin,  $\text{QSTREETTGF}$ ) requests always and so erases the request machinery;  $\text{FG}\neg\beta$  makes  $\beta$  itself the request and forbids response — the ranking certificate must then pay out at every  $\beta$ -visit with nothing ever refunding it, which is exactly a proof that  $\beta$ -visits are finitely many. That both directions are single nodes of one rule — where automaton-primitive designs pay a product construction for one of them — is the practical content of the Streett-primitive choice (see the  $\text{QSTREETTBATTERY}$  section's remark).

| proof step                   | formal anchor                                                                                                     |
|------------------------------|-------------------------------------------------------------------------------------------------------------------|

| twin                         | $\text{QSTREETTGF}$ (recurrence; the member that consumes a chart)                                                |
| constructor builds expansion | the reference implementation's concrete-syntax canonicity battery (documentary; no wire artefact exists to check) |

## Rule 58. QNegFALIAS (alias for QSAFETYBATTERY)

### The rule (Steele metanotation)

as realized in the mechanized development; source row: QTSL-rules.toml — *QNegFALias*. The metanotation statement is typeset by hand for notational quality; its mechanized ground truth is the Lean statement below, extracted from the sources at every build of this book and hash-bound. The rule *roster* is machine-checked (every mechanized rule tag round-trips to exactly one catalogue row); the statement *text* is editorial, checked by eye against the extracted Lean beside it.

$$\frac{\text{child} : \text{QRegionSat}(\text{SProbGE}(p, \text{PAlways}(\text{SNot } \varphi)), R)}{\mathcal{M}, x_0 \in R \models \text{SProbGE}(p, \text{PNotPath}(\text{PDeadline}(T, \varphi, \text{false})))}$$

QNegFALIAS discharges a negated deadline: to certify, with probability at least  $p$ , that  $\varphi$  does *not* occur within horizon  $T$  ( $\neg F_{\leq T} \varphi$ ), it suffices to certify the *unbounded* safety claim —  $\varphi$  never occurs at all — over the same region, and the alias rewrites the one judgment into the other: the child is a satisfaction judgment for always-not- $\varphi$ , the conclusion the negated-deadline judgment, region verbatim. It is an alias to the safety battery (QSAFETYBATTERY): one node to one node, and the entire mathematical content is a two-line denotation inclusion — a path on which  $\varphi$  never holds certainly does not reach  $\varphi$  within  $T$ , and not-reaching-within- $T$  is the bounded-always of the negation. The rewrite is choice-free (no producer parameter beyond the horizon already present in the goal), and the checker recomputes nothing new: the child is an ordinary safety-battery conclusion.

The rule is deliberately lossy in one direction — the unbounded claim is strictly stronger than the bounded one — which is the honest price of reusing the safety kernel with no horizon bookkeeping. A producer who needs the sharp bounded claim (because  $\varphi$  *does* occur eventually, only late) uses the deadline machinery instead; this alias serves the common case where the avoidance is permanent.

Mechanization state, plainly: the bound statements below are the two lines, as priced. `negF_denot_subset` (module `BernsteinLogicAux.QtslAliases`) is the denotation inclusion — a path on which  $\varphi$  never holds does not reach  $\varphi$  within  $T$  — pure path-set algebra, axiom-free (the kernel certifies it depends on no axioms at all); and `sound_QNegFALias` is the alias's transport: a lower bound on the unbounded safety event (the target's conclusion shape, with `sat :=  $\neg\varphi$` ) is a lower bound on the negated-deadline event, for *any* measure on path space — profile-generic, so the discrete-kernel and GSHS records read it alike, and the entry carries no conditional flag.

notes Two flags travel with the row, both from the source catalogue. Tier (flagged, not forced): alias as sorted, but if the folded denotation inclusion must itself be a rule application, the tier moves to admissible — machinery unchanged either way. And the mirror is a deliberate hole: there is no dual rule discharging a negated *always* by a bounded operator, because the conclusion it would need ( $F\varphi$  unbounded) is structurally unrepresentable in the spec grammar — the unbounded-eventually constructor was excluded by testable-negative design, unbounded eventuality surviving only as a producer-choice provenance flag on deadlines. The pair must never be ported as one duality entry: one side is a statable choice-free alias, the other hides a horizon choice and a metatheory line inside the deadline battery.

### Lean statement

BernsteinLogicAux.QtslAliases . **negF\_denot\_subset**

statement bound

```
/-- **The denotation inclusion** (QTSL-rules.toml row `QNegFALias` -
"the denotation inclusion  $\llbracket G \neg \varphi \rrbracket \subseteq \llbracket G_{\leq T} \neg \varphi \rrbracket = \llbracket \neg F_{\leq T} \varphi \rrbracket$ " folds into the
rewrite"; the catalogue's "two lines"): a path on which  $\varphi$  never holds
certainly does not reach  $\varphi$  within  $T$  — and not-reaching-within- $T$  *is*
the negated deadline event. Pure path-set algebra; no measure, no
measurability. -/
theorem negF_denot_subset {S : Type*} (sat : S → Prop) (T : ℕ) :
  {ω : ℕ → S | ∀ n, ¬ sat (ω n)} ⊆ {ω : ℕ → S | ¬ ∃ k ≤ T, sat (ω k)}
```

BernsteinLogicAux.QtslAliases . **sound\_QNegFALias**

statement bound

```
/-- **`sound_QNegFALias`** (rule row `QNegFALias`): the alias's
transport — a lower bound on the probability of the unbounded safety event
(`QSafetyBattery`'s conclusion shape, e.g. `sound_QSafetyBattery` /
`sound_QSafetyBattery_staged` with `sat :=  $\neg\varphi$ `) is a lower bound on the
probability of the negated-deadline event. Profile-generic (any measure on
path space — discrete-kernel and GSHS records alike), by monotonicity
through `negF_denot_subset`. The rewrite is choice-free: no producer
parameter beyond the horizon  $T$  already present in the goal. -/
theorem sound_QNegFALias {S : Type*} [MeasurableSpace S]
  (μ : Measure (ℕ → S)) {sat : S → Prop} {b : ENNReal} {T : ℕ}
  (h : b ≤ μ {ω | ∀ n, ¬ sat (ω n)}) :
  b ≤ μ {ω | ¬ ∃ k ≤ T, sat (ω k)}
```

## Correspondence (Steele display $\leftrightarrow$ Lean)

**reviewer-certified against the displayed texts** The dictionary below is a reviewer-certified statement of how the mechanized statements above interpret the displayed rule: display metavariable  $\mapsto$  Lean binder, each display hypothesis  $\mapsto$  the premise or side condition carrying it, the display conclusion  $\mapsto$  the goal — with any deliberate difference in width between display and mechanization named outright. Certification is recorded as a hash triple over (the displayed cell, the extracted statement texts, this dictionary's own text); if any of the three changes, this block turns amber until a reviewer re-certifies. The correspondence claim itself remains editorial — reviewer-grade, not machine-checked; its machine-checked successor types each soundness statement against the rule as a structured object, and supersedes this block per rule as it lands.

The displayed rewrite — child  $\text{QRegionSat}(\text{SProbGE}(p, \text{PAlways}(\text{SNot } \varphi)), R)$  concluding  $\text{SProbGE}(p, \text{PNotPath}(\text{PDeadline}(T, \varphi, \text{false})))$  —  $\mapsto$  the two-statement chain:  $\text{negF\_denot\_subset}$  (the denotation inclusion  $\{\omega \mid \forall n, \neg \text{sat } (\omega n)\} \subseteq \{\omega \mid \neg \exists k \leq T, \text{sat } (\omega k)\}$  — pure path-set algebra, axiom-free, no measure, no measurability) and  $\text{sound\_QNegFALias}$ , its transport: a lower bound  $b \leq \mu$  on the unbounded-safety event is a lower bound on the negated-deadline event, for *any* measure on path space — profile-generic by binder shape ( $\mu : \text{Measure } (\mathbb{N} \rightarrow S)$  arbitrary), the  $\text{QUNIONBOUND}$  pattern; discrete-kernel and GSHS records alike are instances. The display's choice-freeness is a binder fact: no producer parameter appears beyond the horizon  $T$  already in the goal. Width note: the child's  $\text{SProbGE}$  shape enters only as the abstract bound  $b \leq \mu \{...\}$  — the certified transport is wider than the displayed probabilistic judgment (any  $\text{ENNReal}$  bound transports), safe direction; paths are step-indexed ( $\mathbb{N} \rightarrow S$ ), the deadline read discretely, as at  $\text{TAYLORBOUND}$ .

## Lean verifier receipts

module  $\text{BernsteinLogicAux.QtslAliases}$ ; bound build 570599779c29... (bound from receipt 5a60f4d01fd81ac5, 2026-07-21T05:39:02Z). A receipt records that named checking layers accepted a build: (module, compiled-artifact SHA-256, environment SHA-256, checker layers), minted when the checking gate ran; the store receipts attesting the bound build are listed with the layers each run credited. Nothing here asks the reader to trust the store: every layer is an independently runnable program over the quoted sources — rebuild the module and re-run the checkers to reproduce the verdict. Receipts attesting superseded builds credit no layer and are omitted from this rendering (the count of omissions, if any, is noted below).

| receipt          | minted               | layers                             | status  |

11 further receipt(s) in the store attest superseded builds of this module and are omitted from this rendering.

### gate-layer coverage of the bound build:

build (lake build (elaboration)) **current**

replay (leanchecker (official kernel replay)) **current**

hardened (safe\_verify (hardened screen)) **current**

decorrelated (lean4export + nanoda (decorrelated kernel)) **current**

**comparator: none** no fixture in the three-implementation comparator harness (compiled / kernel-interpreted / reference-interpreted) exercises this rule.

## HOL4 statement

### OUT OF SCOPE BY DESIGN

Out of scope for the HOL side *by design*: the alias unpacks to a single safety-battery node before emission — the wire never carries a negated-deadline node, so the HOL statement that would verify the discharged certificate is the safety battery's own (absent today: the satisfaction stratum has no HOL artefact, per that section). Checked against the HOL sources: the  $\text{bern\_catalogue}$  theory is the base-calculus checker cone and carries no spec-surface path operators.

## HOL verifier receipts

### NONE

no HOL verification receipt exists for this rule.

## Proof

Genre: alias rule (tier 3) — a respelling template; the batch's shared template is Recipe [R50.1](#) of the  $\text{QSTREETTDEGENERATE}$  section. The soundness content is two lines, recorded as such in the source catalogue, and both are now mechanized and bound in the entry: the inclusion ( $\text{negF\_denot\_subset}$ , axiom-free) and its measure transport ( $\text{sound\_QNegFALias}$ , profile-generic).

**Recipe R58.1** (the filled-in application).

$$\frac{\text{child} : \text{QRegionSat}(\text{SProbGE}(p, \text{PAlways}(\text{SNot } \varphi)), R) \text{ (one QSAFETYBATTERY conclusion)}}{\mathcal{M}, x_0 \in R \models \text{SProbGE}(p, \text{PNotPath}(\text{PDeadline}(T, \varphi, \text{false})))} \text{QNEGFAlias}$$

One node to one node: the child is the safety battery's conclusion at avoid set  $\llbracket \varphi \rrbracket$ , the concluded judgment re-reads the same certified region against the negated deadline, horizon  $T$  taken from the goal. In the staged spec vocabulary the conclusion's formula is the negated-path reading of a deadline node whose met-flag is false; the child's is the always of the negation — the rewrite touches the formula only.

|                                          | QNEGFAlias node                                                                                 | QSAFETYBATTERY node                                                                                  |
|------------------------------------------|-------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------|
| <b>Recipe R58.2</b> (payload transport). | certified region $R$ , probability $p$<br>goal formula $\neg F_{\leq T} \varphi$<br>horizon $T$ | verbatim<br>child formula $G \neg \varphi$ (horizon dropped)<br>not consumed ( <b>Remark R58.5</b> ) |

Unpack-function slot: no verified payload function in this edition (batch template); the semantic witness is bound in the entry (negF\_denot\_subset + sound\_QNegFAlias).

**Proposition R58.3** (the exactness inclusion — two lines).  $\llbracket G \neg \varphi \rrbracket \subseteq \llbracket G_{\leq T} \neg \varphi \rrbracket = \llbracket \neg F_{\leq T} \varphi \rrbracket$ .

*Proof.* A path that never satisfies  $\varphi$  in particular does not satisfy  $\varphi$  at any time  $\leq T$  — the inclusion, by restriction of a universal quantifier. And not satisfying  $\varphi$  at any time  $\leq T$  is the definition of not reaching  $\varphi$  within  $T$  — the equality, definitional. Hence every path in the child's path set lies in the conclusion's, and the probability bound transports monotonically.  $\square$

**Proposition R58.4** (soundness corollary). *If the child judgment holds — from every state of  $R$ , with probability  $\geq p$  the path always avoids  $\llbracket \varphi \rrbracket$  — then from every state of  $R$ , with probability  $\geq p$  the path does not reach  $\llbracket \varphi \rrbracket$  within  $T$ .*

*Proof.* Proposition **R58.3** plus monotonicity of measures, applied under the safety battery's theorem. There is no other content — and this two-step corollary is precisely what the bound statements are: the inclusion and the transport, one decl each.  $\square$

**Remark R58.5** (the deliberate lossiness). The alias proves the bounded claim from the unbounded one, discarding  $T$ . When  $\varphi$  genuinely occurs eventually — only after the horizon — the child judgment is unprovable and this alias is the wrong tool; the deadline machinery (the deadline battery, with its geometric decay certificates) proves the sharp bounded claim instead. The alias exists because permanent avoidance is the common case, and for it the safety kernel is both cheaper and already ported.

**Remark R58.6** (the mirror that is not a rule). There is deliberately no dual entry discharging a negated *always*: its conclusion would need unbounded eventuality ( $F\varphi$ ), and the spec grammar has no unbounded-eventually constructor — an exclusion by testable-negative design, unbounded eventuality surviving only as a provenance flag recording that a deadline's horizon was producer-chosen. What replaces the missing rule is three separate pieces: a negation-normal-form duality (QNNFREWITE), a horizon instantiation (a producer choice, flagged), and a weakening line *inside* the deadline battery's lemma where the flag is discharged. The asymmetry is worth this remark because a port that treated the pair as one duality entry would smuggle a choice and a metatheory line into what looks like a definitional rewrite.

**Remark R58.7** (tier flag). Alias as sorted; if the folded inclusion of Proposition **R58.3** must itself be a rule application rather than a lemma of the unpack, the tier moves to admissible — flagged in the source catalogue, machinery unchanged either way.

| proof step                           | formal anchor                                                                   |
|--------------------------------------|---------------------------------------------------------------------------------|
| Recipe <b>R58.1</b> target           | the QSAFETYBATTERY section                                                      |
| Proposition <b>R58.3</b> + corollary | negF_denot_subset + sound_QNegFAlias (two lines, as priced; bound in the entry) |
| Remark <b>R58.6</b>                  | the spec grammar's constructor census (no unbounded-eventually node)            |

## 15.7 Discharge Kits, Closure, and Arithmetic Leaves

### Rule 59. HYPMULTIPLIER (admissible rule)

#### The rule (Steele metanotation)

as realized in the mechanized development; source row: QTSL-rules.toml — *HypMultiplier*. The metanotation statement is typeset by hand for notational quality; its mechanized ground truth is the Lean statement below, extracted from the sources at every build of this book and hash-bound. The rule *roster* is machine-checked (every mechanized rule tag round-trips to exactly one catalogue row); the statement *text* is editorial, checked by eye against the extracted Lean beside it.

$$\frac{\vdash \lambda \geq 0 \text{ on cell} \quad \vdash N + \lambda g_q \leq 0 \text{ on cell}}{\vdash N \leq 0 \text{ on cell} \cap \{g_q \geq 0\}}$$

the child atom  $\{g_q \geq 0\}$  is a concluded child certificate's region.

the child atom enters through the presentation bridge; both premises are BERNCONe-family rows, replayed by the base kernel — realized as the verified pointwise warrant `hypMultiplier_sound`.

HYPMULTIPLIER is the discharge kit's multiplier move, and the only member of the kit that manufactures a new row rather than reshaping the scope of an existing one. The situation it serves: a premise row of a satisfaction-judgment rule must hold not on a whole cell but on the part of the cell where a child certificate's region atom holds —  $N \leq 0$  on  $\text{cell} \cap \{g_q \geq 0\}$ , with  $\{g_q \geq 0\}$  the region concluded by a nested certificate. The base calculus's rows are scoped to cells, not to cell-with-polynomial-atom intersections, so the obligation cannot be posted as a base row directly. The rule buys the restriction with one multiplier: exhibit  $\lambda$  and post two ordinary cone-family rows —  $\lambda \geq 0$  on the cell, and  $N + \lambda g_q \leq 0$  on the cell.

What the checker recomputes: nothing beyond the two premise rows, which are cone-membership sequents the base kernel already replays; the combination step is the degree-one corner of the positivstellensatz family, the same multiplier discipline as the calculus's Farkas machinery. The producer typically finds  $\lambda$  by linear programming; only the two rows ship.

Both hypotheses are load-bearing, in opposite ways. Drop the sign row and a negative multiplier flips the direction of the trade: with  $N \equiv 1$ ,  $\lambda \equiv -1$ ,  $g_q \equiv 1$ , the combined row  $N + \lambda g_q \equiv 0 \leq 0$  holds while the conclusion fails everywhere on the child atom. Widen the conclusion to the whole cell and the rule is unsound wherever the child atom fails: where  $g_q(x) < 0$  the term  $\lambda(x) g_q(x)$  is a subsidy rather than a tax, and the combined row bounds nothing. The proof section walks both, counterexamples attached.

**notes** Before this rule's mechanization, the move lived in the producer toolkit as unchecked metatheory — the discharge step performed the combination and asserted the scoped row. The verified lemma closes that trust boundary. The certificate row that would let the wire format carry the move natively is out of scope of the current baked theory, so today the lemma warrants the toolkit's elaboration rather than a kernel-replayed node.

#### Lean statement

The auxiliary library states the extension theory's structural lemmas over the compiled semantic class: a bare state type, scopes and cells as sets, observables as real-valued functions. The presentation-level child atom enters through the named bridge hypothesis (`hbridge`), which the presentation layer discharges definitionally at compile time; nothing else about the system enters at all.

`BernsteinLogicAux.Structural.hypMultiplier_sound`

statement bound

```
/-- **T2 HypMultiplier**, soundness. `childAtom` is the presentation-level
child atom; its bridge names the compiled superlevel reading `{x | 0 ≤ g x}`.
The premises are the two compiled BernCone-family rows. -/
theorem hypMultiplier_sound (cell childAtom : Set X) (N lam g : X → ℝ)
  (hbridge : childAtom = {x | 0 ≤ g x})
  (hlam : ∀ x ∈ cell, 0 ≤ lam x)
  (hcomb : ∀ x ∈ cell, N x + lam x * g x ≤ 0) :
  ∀ x ∈ cell ∩ childAtom, N x ≤ 0
```

#### Correspondence (Steele display ↔ Lean)

**reviewer-certified against the displayed texts** The dictionary below is a reviewer-certified statement of how the mechanized statements above interpret the displayed rule: display metavariable  $\mapsto$  Lean binder, each display hypothesis  $\mapsto$  the premise or side condition carrying it, the display conclusion  $\mapsto$  the goal — with any deliberate difference in width between display and mechanization named outright. Certification is recorded as

a hash triple over (the displayed cell, the extracted statement texts, this dictionary's own text); if any of the three changes, this block turns amber until a reviewer re-certifies. The correspondence claim itself remains editorial — reviewer-grade, not machine-checked; its machine-checked successor types each soundness statement against the rule as a structured object, and supersedes this block per rule as it lands.

One bound statement, transcription-close. The displayed premises  $\vdash \lambda \geq 0$  on cell and  $\vdash N + \lambda g_q \leq 0$  on cell  $\mapsto$  hlam/hcomb, pointwise on cell; the conclusion  $\vdash N \leq 0$  on cell  $\cap \{g_q \geq 0\} \mapsto$  the goal  $\forall x \in \text{cell} \cap \text{childAtom}, N x \leq 0$ , with the child atom entering through the System-bridge hypothesis hbridge : childAtom = {x | 0 ≤ g x} — the presentation-level region named by an equality the presentation layer will discharge definitionally; until then it is an honest binder, not an assertion. Width note: N, lam, g are arbitrary real-valued functions and cell an arbitrary set — the BernCone row structure and polynomiality are consumed one layer down where the rows are replayed; the certified warrant is the pointwise Farkas step alone, degree-1 positivstellensatz as displayed, strictly wider than the polynomial instance, safe direction.

## Lean verifier receipts

module BernsteinLogicAux.Structural; bound build 1222cdcc326f... (bound from receipt cb0c3820c6877f22, 2026-07-29T01:03:36Z). A receipt records that named checking layers accepted a build: (module, compiled-artifact SHA-256, environment SHA-256, checker layers), minted when the checking gate ran; the store receipts attesting the bound build are listed with the layers each run credited. Nothing here asks the reader to trust the store: every layer is an independently runnable program over the quoted sources — rebuild the module and re-run the checkers to reproduce the verdict. Receipts attesting superseded builds credit no layer and are omitted from this rendering (the count of omissions, if any, is noted below).

## HOL4 statement

### NO HOL STATEMENT YET

The HOL4 development's object is the base calculus's wire-format checker (theory bern\_catalogue ports the catalogue check-function cone). This rule belongs to the extension theory's discharge kit: it postdates that port, and no row for the move exists in the baked theory — there is nothing for a HOL statement to be about. The box becomes fillable when a revision carries the move's certificate rows and the corresponding check is ported.

## HOL verifier receipts

### NONE

no HOL verification receipt exists for this rule.

## Proof

Genre: admissible rule (tier 2) — a proof-tree-rewriting recipe; the general admissible template, both species included, is stated in the NORM section and instantiated here in its boundary species (discharge against a named verified theorem). The rule is sequent-side machinery: premises and conclusion are all  $\vdash$  rows, and what the extension theory contributes is the *scope* vocabulary — the child atom  $\{g_q \geq 0\}$  names a region concluded by a nested certificate, a shape no base cell can express. The rule closes a named trust boundary: before its mechanization, the move was performed producer-side and asserted.

**Recipe R59.1** (the `HYPMULTIPLIER` instance).

$$\frac{\mathcal{T}_\lambda \triangleright \vdash \lambda \geq 0 \text{ on cell} \quad \mathcal{T}_c \triangleright \vdash N + \lambda g_q \leq 0 \text{ on cell}}{\vdash N \leq 0 \text{ on cell} \cap \{g_q \geq 0\}} \quad \text{HYPMULTIPLIER} \rightsquigarrow \begin{array}{l} \text{the premise subtrees stand unchanged;} \\ \text{hypMultiplier\_sound discharges the scoped row.} \end{array}$$

The rewrite is degenerate in the same honest sense as the base catalogue's ground-fact rule: the conclusion is not derivable from catalogue nodes, because the base grammar has no row form scoped to a cell-with-polynomial-atom intersection — that scope exists one layer up, where the child certificate that concluded  $\{g_q \geq 0\}$  lives. The two premise subtrees are ordinary cone-family derivations, checked by the base kernel unchanged; the node itself discharges against the verified pointwise warrant below, which consumes the two premises plus the one bridge hypothesis naming the child atom's compiled reading (the closing remark) — and nothing else.

**Proposition R59.2** (semantic warrant). *If  $\lambda \geq 0$  everywhere on the cell and  $N + \lambda g_q \leq 0$  everywhere on the cell, then  $N \leq 0$  everywhere on  $\text{cell} \cap \{g_q \geq 0\}$ .*

*Proof.* Fix  $x$  in the intersection. Then  $g_q(x) \geq 0$  (membership in the child atom) and  $\lambda(x) \geq 0$  (the sign row), so  $\lambda(x) g_q(x) \geq 0$ , and

$$N(x) \leq N(x) + \lambda(x) g_q(x) \leq 0,$$

the first inequality by nonnegativity of the added term, the second by the combined row at  $x$ . That is the whole proof — `hypMultiplier_sound` is the two displayed inequalities.  $\square$

*Remark R59.3* (the sign row is half the rule). Drop  $\vdash \lambda \geq 0$  and the rule is unsound. Counterexample:  $N \equiv 1$ ,  $\lambda \equiv -1$ ,  $g_q \equiv 1$  on any nonempty cell (a singleton suffices). The combined row holds identically ( $1 - 1 = 0 \leq 0$ ), yet  $N \equiv 1$  fails everywhere on  $\text{cell} \cap \{g_q \geq 0\} = \text{cell}$ . A free-signed multiplier converts the tax the child atom levies into a subsidy: the combination can cancel exactly the positivity the conclusion denies.

*Remark R59.4* (the scope restriction is the other half). The conclusion cannot claim the whole cell. With  $N \equiv 1$ ,  $\lambda \equiv 1$ ,  $g_q \equiv -1$  on the same nonempty cell, both premises hold ( $\lambda \geq 0$ ;  $1 - 1 = 0 \leq 0$ ) while  $N > 0$  everywhere — and the rule is nonetheless sound, because  $\text{cell} \cap \{g_q \geq 0\} = \emptyset$  and the scoped claim is vacuous. Where  $g_q(x) < 0$  the term  $\lambda(x) g_q(x)$  subsidizes  $N$  instead of taxing it, and the combined row bounds nothing: the scoped conclusion is exactly as strong as the premises pay for, no stronger.

*Remark R59.5* (degree-one positivstellensatz, and where the search lives). The move is the degree-one corner of certifying positivity over a constrained set by nonnegative combinations: Farkas' multiplier discipline [73] (see [216] for the sign conventions) in the affine case, sitting at the bottom of the polynomial cone hierarchy of Krivine [144] and Handelman [110] that the calculus's cone rule draws on. Nothing beyond degree one is consumed here: one multiplier, one product, no certificate machinery beyond the two posted rows. The *search* for  $\lambda$  (typically a linear program over the cone-membership witnesses) is producer-side; only its result ships, and the checker replays the two rows without ever seeing the search.

*Remark R59.6* (the bridge hypothesis). In the verified statement the child atom is an abstract set with one bridge hypothesis naming its compiled superlevel reading ( $\{x \mid 0 \leq g_q(x)\}$ ). When the presentation layer of the extension theory lands, the hypothesis discharges definitionally from the compile — the scoped conclusion itself is unchanged; only the bridge binder becomes definitional. Until then it is the honest record of exactly what the warrant assumes about the child certificate's conclusion — its region is the superlevel set it claims to be, and nothing more.

| proof step            | formal anchor                                                                                                   |
|-----------------------|-----------------------------------------------------------------------------------------------------------------|

## Rule 60. QFullDomainWeaken (alias rule)

### The rule (Steele metanotation)

as realized in the mechanized development; source row: `QTSL-rules.toml` — *QFullDomainWeaken*. The metanotation statement is typeset by hand for notational quality; its mechanized ground truth is the Lean statement below, extracted from the sources at every build of this book and hash-bound. The rule *roster* is machine-checked (every mechanized rule tag round-trips to exactly one catalogue row); the statement *text* is editorial, checked by eye against the extracted Lean beside it.

$$\frac{\vdash P \text{ on } D_m \quad \text{scope} \subseteq D_m \text{ (compile fact, not a posted premise)}}{\vdash P \text{ on scope}}$$

emitted shape:  $\text{scope} = D_m \setminus \text{Off}$  (the off-scoped row).

payload verbatim, scope replaced — one application at the region layer, realized as `fullDomainWeaken_sound` (axiom-free) + `_offScope`.

QFullDomainWeaken is the cheapest move in the discharge kit: an off-scoped row — an obligation  $P$  on  $D_m \setminus \text{Off}$ , the part of a mode's domain outside an off-region — is discharged by proving  $P$  on all of  $D_m$  and forgetting the carve-out. It is an alias: one scope-weakening application at the region layer, transporting the row payload verbatim and replacing the scope by the full domain.

A producer reaches for it first. When the row happens to hold globally, the off-region was doing no work for this row, and the discharge costs nothing beyond the containment of the scope in the domain — which is a compile guarantee, not a posted premise. When the global row fails (the off-region was earning its keep), the move is simply unavailable, and the kit's working move, QVerifiedCover, localizes the effort instead.

What the checker recomputes: nothing. Soundness is the monotonicity of universal quantification — a row asserted on a superset restricts to any subset — and the verified lemma is a one-line restriction along an inclusion, provable without any classical reasoning at all.

notes Two deliberate non-identifications. First, the alias's target is not a catalogue node: no region-weakening rule exists to apply, and the unpacking discharges directly against the verified monotonicity lemma — the alias-tier twin of the admissible tier's recorded reduction-to-verified-machinery boundary case. Second, the rule is deliberately NOT the base calculus's sequent weakening: that rule manages a sequent's premise list; this one manages the region a row is quantified over, one extension layer up. Unifying them would conflate two different quantifiers that merely rhyme.

### Lean statement

Stated over the compiled semantic class (sets over a bare state type). The off-scoped shape the discharge plan actually emits is the second declaration, an instance of the first; the scope-in-domain containment enters as the bridge hypothesis the compile guarantees.

BernsteinLogicAux.Structural .fullDomainWeaken\_sound

statement bound

```
/-- **T3a FullDomainWeaken**, soundness. `scope` is the presentation-level
off-scoped row's scope; the bridge names the one fact the compile
guarantees about it: it lies inside the full domain. -/
theorem fullDomainWeaken_sound (Dm scope : Set X) (P : X → Prop)
  (hbridge : scope ⊆ Dm)
  (hrow : ∀ x ∈ Dm, P x) :
  ∀ x ∈ scope, P x
```

BernsteinLogicAux.Structural .fullDomainWeaken\_offScope

statement bound

```
/-- The off-scope instance: the scope compiled as `D_m` minus an off-region.
(The shape the discharge plan actually emits.) -/
theorem fullDomainWeaken_offScope (Dm Off : Set X) (P : X → Prop)
  (hrow : ∀ x ∈ Dm, P x) :
  ∀ x ∈ Dm \ Off, P x
```

### Correspondence (Steele display ↔ Lean)

reviewer-certified against the displayed texts The dictionary below is a reviewer-certified statement of how the mechanized statements above interpret the displayed rule: display metavariable  $\mapsto$  Lean binder, each display hypothesis  $\mapsto$  the premise or side condition carrying it, the display

conclusion  $\mapsto$  the goal — with any deliberate difference in width between display and mechanization named outright. Certification is recorded as a hash triple over (the displayed cell, the extracted statement texts, this dictionary's own text); if any of the three changes, this block turns amber until a reviewer re-certifies. The correspondence claim itself remains editorial — reviewer-grade, not machine-checked; its machine-checked successor types each soundness statement against the rule as a structured object, and supersedes this block per rule as it lands.

The displayed premise  $\vdash P$  on  $D_m \mapsto \text{hrow} : \forall x \in D_m, P\ x$ ; the compile fact scope  $\subseteq D_m$  — displayed as “not a posted premise” —  $\mapsto$  the System-bridge hypothesis  $\text{hbridge} : \text{scope} \subseteq D_m$ , an explicit binder here because lean-aux lacks the compile layer that guarantees it; the conclusion  $\mapsto \forall x \in \text{scope}, P\ x$ . The emitted shape  $\text{scope} = D_m \setminus \text{Off}$  is bound separately as  $\text{fullDomainWeaken\_offScope}$ , where the bridge discharges by  $\text{Set.diff\_subset}$  — zero hypotheses beyond the row. Width note:  $P : X \rightarrow \text{Prop}$  arbitrary (payload verbatim, as displayed — the certified statement cannot even see the payload, which is the strongest possible form of “payload verbatim, scope replaced”); the root statement is axiom-free pure  $\forall$ -monotonicity, exactly the alias tier's price.

## Lean verifier receipts

module BernsteinLogicAux.Structural; bound build 1222cdcc326f... (bound from receipt cb0c3820c6877f22, 2026-07-29T01:03:36Z). A receipt records that named checking layers accepted a build: (module, compiled-artifact SHA-256, environment SHA-256, checker layers), minted when the checking gate ran; the store receipts attesting the bound build are listed with the layers each run credited. Nothing here asks the reader to trust the store: every layer is an independently runnable program over the quoted sources — rebuild the module and re-run the checkers to reproduce the verdict. Receipts attesting superseded builds credit no layer and are omitted from this rendering (the count of omissions, if any, is noted below).

| receipt          | minted               | layers                             | status  |

11 further receipt(s) in the store attest superseded builds of this module and are omitted from this rendering.

### gate-layer coverage of the bound build:

build (lake build (elaboration)) current

replay (leanchecker (official kernel replay)) current

hardened (safe\_verify (hardened screen)) current

decorrelated (lean4export + nanoda (decorrelated kernel)) current

comparator: none no fixture in the three-implementation comparator harness (compiled / kernel-interpreted / reference-interpreted) exercises this rule.

## HOL4 statement

### NO HOL STATEMENT YET

The HOL4 development's object is the base calculus's wire-format checker (theory bern\_catalogue ports the catalogue check-function cone). This rule is scope machinery of the extension theory's discharge kit: it postdates that port, and no row for the move exists in the baked theory — there is nothing for a HOL statement to be about. The box becomes fillable when a revision carries the move's certificate rows and the corresponding check is ported.

## HOL verifier receipts

### NONE

no HOL verification receipt exists for this rule.

## Proof

Genre: alias rule (tier 3) — a respelling template. An alias owes the book five artefacts: the verified  $1 \rightarrow 1$  unpack, the filled-in application of the target, the payload-transport table, the exactness identity, and the soundness corollary through the target's lemma. This alias is the tier's degenerate case — its target is a verified lemma rather than a catalogue node, because no region-weakening rule exists to apply — and the five artefacts below say so honestly rather than inventing a node.

**Recipe R60.1** (the alias template, degenerate-target form). An alias rule  $A$  is warranted by a verified function carrying its payload to the payload of a *single* target application — one node  $\rightarrow$  one node, nothing derived. Where the target is not a catalogue node but a verified theorem, the transport carries the payload into the theorem's hypotheses instead, and the soundness corollary is the theorem itself: the alias-tier twin of the admissible tier's recorded reduction-to-verified-machinery boundary case.

**Recipe R60.2** (the filled-in application).

$$\frac{\mathcal{T} \triangleright \vdash P \text{ on } D_m}{\vdash P \text{ on } D_m \setminus \text{Off}} \text{QFULLDOMAINWEAKEN} \rightsquigarrow \text{fullDomainWeaken\_offScope}[\mathcal{T}] \triangleright \vdash P \text{ on } D_m \setminus \text{Off}$$

with the general form — any scope the compile certifies inside the domain — carried by `fullDomainWeaken_sound`: from  $P$  on  $D_m$  and  $\text{scope} \subseteq D_m$ , conclude  $P$  on  $\text{scope}$ .

|                                          | off-scoped row                                                               | full-domain row                                                                                       |
|------------------------------------------|------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------|
| <b>Recipe R60.3</b> (payload transport). | row payload $P$<br>scope $D_m \setminus \text{Off}$<br>scope $\subseteq D_m$ | $P$ (verbatim)<br>$D_m$ (the off-region dropped)<br>compile guarantee (hbridge), not a posted premise |

**Proposition R60.4** (exactness identity).  $D_m \setminus \text{Off} \subseteq D_m$ ; more generally, every off-scoped row's scope is contained in its mode's domain.

*Proof.* A set difference is contained in its left operand — one line (`Set.diff_subset`). The general containment is the compile fact the bridge hypothesis names, supplied by the presentation layer, never proven per-instance.  $\square$

**Proposition R60.5** (soundness corollary). If  $P$  holds everywhere on  $D_m$ , it holds everywhere on any  $\text{scope} \subseteq D_m$  — in particular on  $D_m \setminus \text{Off}$ .

*Proof.* Restriction of a universally quantified statement along an inclusion: for  $x \in \text{scope}$ , the inclusion gives  $x \in D_m$ , and the full-domain row gives  $P(x)$ . `fullDomainWeaken_sound` is this one line, and it is axiom-free — no classical reasoning, no choice: pure monotonicity of  $\forall$ .  $\square$

**Remark R60.6** (what is spent). Nothing, soundness-wise — and possibly everything, feasibility-wise: if  $P$  fails anywhere in  $D_m \cap \text{Off}$  (points of the off-region outside  $D_m$  never enter the row), the full-domain row is simply unprovable and the move is unavailable. The off-region existing at all signals that some row somewhere needed it; this move is the discharge for the rows that did not, and its availability is itself a diagnosis: the carve-out was free for this row. When it fails, the kit's working move (`QVERIFIEDCOVER`) localizes the work instead of abandoning the carve-out.

**Remark R60.7** (deliberately not the sequent weakening). The base calculus has a weakening rule; this is deliberately not it. Sequent weakening grows a premise *list* — what a sequent assumes; this move shrinks a quantification *region* — where a row is asserted. The two live one extension layer apart and neither subsumes the other: a base sequent has no scope field to weaken, and this move never touches a premise list. The kinship is real, and the identification would be a type error.

| proof step                                                     | formal anchor                                                                                                  |

## Rule 61. QVERIFIEDCOVER (admissible rule)

### The rule (Steele metanotation)

as realized in the mechanized development; source row: QTSL-rules.toml — *QVerifiedCover*. The metanotation statement is typeset by hand for notational quality; its mechanized ground truth is the Lean statement below, extracted from the sources at every build of this book and hash-bound. The rule *roster* is machine-checked (every mechanized rule tag round-trips to exactly one catalogue row); the statement *text* is editorial, checked by eye against the extracted Lean beside it.

$$\frac{\vdash P \text{ on } C \text{ (the cover row)} \quad \{\vdash K_i \subseteq \text{Off}\}_i \text{ (per-component containments)} \quad D_m \setminus C \subseteq \bigcup_i K_i \text{ (residual decomposition)}}{\vdash P \text{ on } D_m \setminus \text{Off}}$$

the per-component containments discharge by exact Bernstein upper bounds, and the residual decomposition is recomputed by the checker. Dimension-free as realized (*verifiedCover\_components\_sound*, arbitrary component index); the cover bookkeeping  $C \subseteq D_m$  is checker-side well-formedness, not consumed by soundness.

QVERIFIEDCOVER is the discharge kit's working move: an off-scoped row —  $P \text{ on } D_m \setminus \text{Off}$  — is discharged by proving the row on a cover  $C$  and certifying that everything of  $D_m$  the cover misses lies inside the off-region. The un-covered residual is decomposed into components  $K_i$ , and each component ships one containment premise  $K_i \subseteq \text{Off}$ , discharged by exact Bernstein upper bounds — ordinary sequent rows the base kernel replays.

A producer reaches for it when QFULLDOMAINWEAKEN fails — the row genuinely needs its carve-out — but the on-region can be covered cleanly. Cover *selection* is producer-side search (the current toolkit selects one-dimensional covers); the verified statement is dimension-free, so richer covers need no new warrant.

What the checker recomputes: the residual decomposition  $D_m \setminus C \subseteq \bigcup_i K_i$  (set bookkeeping over the posted components) and the per-component containment rows. The case analysis is exhaustive by construction: a point of the scope is either covered, and the row-on- $C$  premise applies, or un-covered, in which case it lies in some  $K_i \subseteq \text{Off}$  — contradicting membership in the scope. Drop the per-component containments and an un-covered point outside the off-region escapes both cases; drop the decomposition and the component list could silently miss part of the residual.

**notes** One premise of the catalogued statement is deliberately absent from the verified one: the cover bookkeeping  $C \subseteq D_m$ . The proof never consumes it — a cover reaching outside the domain proves more rows than needed, harmlessly — so the mechanized statement omits it, which is strictly stronger in the sound direction; the checker keeps the containment as cover well-formedness. The neighbouring scope-preparation steps (hull closure, cell covers, off-scope splitting, reset containment, floor boxes) are deliberately not rules at all: they are side conditions the checker recomputes, and rows for them would misstate that.

### Lean statement

Stated over the compiled semantic class (sets over a bare state type), dimension-free. The residual form is the kernel statement; the per-component form is the shape the discharge plan emits, with an arbitrary component index — nothing one-dimensional survives into the warrant.

BernsteinLogicAux.Structural.**verifiedCover\_sound**

statement bound

```
/-- **T3b VerifiedCover**, soundness (residual form). `scope` is the
off-scoped row's compiled scope `D_m \ Off`; the row is proven on the cover
`C`, and the un-covered residual `D_m \ C` is certified inside the
off-region. -/
theorem verifiedCover_sound (Dm C Off scope : Set X) (P : X → Prop)
  (hbridge : scope = Dm \ Off)
  (hrowC : ∀ x ∈ C, P x)
  (hresidual : Dm \ C ⊆ Off) :
  ∀ x ∈ scope, P x
```

BernsteinLogicAux.Structural.**verifiedCover\_components\_sound**

statement bound

```
/-- **T3b VerifiedCover**, per-component form: the residual is decomposed
into components `K i`, each separately certified inside the off-region (the
"exact Bernstein upper bounds" premises, one per component). -/
theorem verifiedCover_components_sound {ι : Type*} (Dm C Off scope : Set X)
  (K : ι → Set X) (P : X → Prop)
  (hbridge : scope = Dm \ Off)
  (hrowC : ∀ x ∈ C, P x)
```

```

(hdecomp : Dm \ C ⊆ ⋃ i, K i)
(hcomp : ∀ i, K i ⊆ Off) :
∀ x ∈ scope, P x

```

## Correspondence (Steele display ↔ Lean)

**reviewer-certified against the displayed texts** The dictionary below is a reviewer-certified statement of how the mechanized statements above interpret the displayed rule: display metavariable  $\mapsto$  Lean binder, each display hypothesis  $\mapsto$  the premise or side condition carrying it, the display conclusion  $\mapsto$  the goal — with any deliberate difference in width between display and mechanization named outright. Certification is recorded as a hash triple over (the displayed cell, the extracted statement texts, this dictionary's own text); if any of the three changes, this block turns amber until a reviewer re-certifies. The correspondence claim itself remains editorial — reviewer-grade, not machine-checked; its machine-checked successor types each soundness statement against the rule as a structured object, and supersedes this block per rule as it lands.

The displayed premises map onto `verifiedCover_components_sound` one for one: the cover row  $\vdash P$  on  $C \mapsto \text{hrowC}$ ; the per-component containments  $K_i \subseteq \text{Off} \mapsto \text{hcomp} : \forall i, K i \subseteq \text{Off}$  (the exact-Bernstein-upper-bound premises, one per component, over an *arbitrary* index type — the dimension-freedom the flavor text claims is a binder fact); the recomputed residual decomposition  $D_m \setminus C \subseteq \bigcup_i K_i \mapsto \text{hdecomp}$ , an explicit hypothesis (recompute rendered as binder, the `QSTREETTARGETCELLCOLLAPSE` pattern); the conclusion scope  $D_m \setminus \text{Off} \mapsto$  the System-bridge equality `hbridge : scope = Dm \ Off`. The residual form `verifiedCover_sound` is the same statement with the decomposition pre-collapsed. Width note, divergence `D1` as certified: the catalogued well-formedness  $C \subseteq D_m$  appears in `NO` binder — soundness demonstrably never consumes it, which the module header banks as the divergence and the flavor text carries; payload `P` arbitrary, per the `QFullDomainWeaken` pattern.

## Lean verifier receipts

module `BernsteinLogicAux.Structural`; bound build 1222cdcc326f... (bound from receipt cb0c3820c6877f22, 2026-07-29T01:03:36Z).  hardened (safe\_verify (hardened screen)) **current**  
 decorrelated (lean4export + nanoda (decorrelated kernel)) **current**

**comparator:** none no fixture in the three-implementation comparator harness (compiled / kernel-interpreted / reference-interpreted) exercises this rule.

## HOL4 statement

### NO HOL STATEMENT YET

The HOL4 development's object is the base calculus's wire-format checker (theory `bern_catalogue` ports the catalogue check-function cone). This rule is scope machinery of the extension theory's discharge kit: it postdates that port, and no row for the move exists in the baked theory — there is nothing for a HOL statement to be about. The box becomes fillable when the extension's certificate rows land in a wire format and the corresponding check is ported.

## HOL verifier receipts

**NONE**

no HOL verification receipt exists for this rule.

**Proof**

Genre: admissible rule (tier 2) — a proof-tree-rewriting recipe. The rule discharges an off-scoped row by an exhaustive case analysis: prove the row on a cover, certify everything un-covered into the off-region. Its premises are ordinary sequent rows; the case analysis is the verified content.

The admissible template, general form, is stated once for the whole catalogue as Recipe **R16.1** of the **NORM** section; this section instantiates it.

**Recipe R61.1** (the  $\text{QVERIFIEDCOVER}$  instance).

$$\frac{\mathcal{T}_C \triangleright \vdash P \text{ on } C \quad \{ \mathcal{T}_i \triangleright \vdash K_i \subseteq \text{Off} \}_i \quad D_m \setminus C \subseteq \bigcup_i K_i}{\vdash P \text{ on } D_m \setminus \text{Off}} \quad \text{QVERIFIEDCOVER} \quad \begin{array}{l} \text{premise subtrees stand;} \\ \text{verifiedCover\_components\_sound} \\ \text{discharges the scoped row.} \end{array}$$

The per-component containments  $K_i \subseteq \text{Off}$  are exact Bernstein upper-bound rows — ordinary sequents the base kernel replays; the residual decomposition is checker-recomputed set bookkeeping over the posted components, not a proof obligation. The node discharges against the verified case analysis below.

**Proposition R61.2** (semantic warrant, residual form). *If  $P$  holds everywhere on  $C$  and  $D_m \setminus C \subseteq \text{Off}$ , then  $P$  holds everywhere on  $D_m \setminus \text{Off}$ .*

*Proof.* Fix  $x \in D_m \setminus \text{Off}$  and split on membership in the cover. If  $x \in C$ , the cover row gives  $P(x)$ . If  $x \notin C$ , then  $x \in D_m \setminus C \subseteq \text{Off}$  — contradicting  $x \notin \text{Off}$ . The two cases are exhaustive, so the second is vacuous and the first decides ( $\text{verifiedCover\_sound}$ ).  $\square$

**Proposition R61.3** (semantic warrant, per-component form). *If  $P$  holds everywhere on  $C$ , the residual decomposes as  $D_m \setminus C \subseteq \bigcup_i K_i$ , and each component satisfies  $K_i \subseteq \text{Off}$ , then  $P$  holds everywhere on  $D_m \setminus \text{Off}$ .*

*Proof.* The union of the components is contained in  $\text{Off}$  (each is), so  $D_m \setminus C \subseteq \text{Off}$  and Proposition **R61.2** applies ( $\text{verifiedCover\_components\_sound}$ ). The component index is an arbitrary type: no finiteness, no dimension, no ordering of components is consumed.  $\square$

**Remark R61.4** (each premise family is load-bearing). Drop the cover row and any  $x \in C \cap (D_m \setminus \text{Off})$  with  $P(x)$  false refutes the conclusion while both set-bookkeeping premises hold. Drop the per-component containments and an un-covered point outside the off-region escapes both cases:  $x \in D_m \setminus C$  with  $x \notin \text{Off}$  and  $P(x)$  false refutes the conclusion while the remaining premises hold. Drop the residual decomposition and the component list can silently miss part of the residual — the same point, now lying in no  $K_i$ , escapes again. The exhaustiveness of the case analysis is exactly the conjunction of the last two; the cover row is what it decides to.

**Remark R61.5** (the omitted premise — deliberate, and in the sound direction). The catalogued statement carries a cover-bookkeeping premise  $C \subseteq D_m$ ; the verified statement omits it, because the proof never consumes it: a cover reaching outside the domain proves more rows than needed, harmlessly. Omitting an un-consumed hypothesis makes the mechanized statement strictly stronger, in the sound direction — the checker retains the containment as cover *well-formedness*, which is where it belongs.

**Remark R61.6** (the kit as a spectrum). The corner  $C = D_m$  (empty residual, no components) is  $\text{QFULLDOMAINWEAKEN}$ ; the opposite corner  $C = \emptyset$  demands the entire domain certified into the off-region, at which point the scope is empty and the row vacuous. Between the corners, the cover is the dial trading global proof effort against per-component containment certificates — and cover *selection* is producer-side search (one-dimensional in the current toolkit), spent before anything ships. The verified statement is dimension-free: richer covers change the search, never the warrant.

## Rule 62. QPOSITIVECOMBINATIONROOT (admissible rule)

### The rule (Steele metanotation)

as realized in the mechanized development; source row: QTSL-rules.toml — *QPositiveCombinationRoot*. The metanotation statement is typeset by hand for notational quality; its mechanized ground truth is the Lean statement below, extracted from the sources at every build of this book and hash-bound. The rule *roster* is machine-checked (every mechanized rule tag round-trips to exactly one catalogue row); the statement *text* is editorial, checked by eye against the extracted Lean beside it.

$$\frac{\text{child}_1 : \text{QRegionSat}(\varphi_1, R_1) \quad \text{child}_2 : \text{QRegionSat}(\varphi_2, R_2)}{\mathcal{M}, x_0 \in R_1 \cap R_2 \models \varphi_1 \wedge \varphi_2}$$

$$\frac{\text{child}_1 : \text{QRegionSat}(\varphi_1, R_1) \quad \text{child}_2 : \text{QRegionSat}(\varphi_2, R_2)}{\mathcal{M}, x_0 \in R_1 \cup R_2 \models \varphi_1 \vee \varphi_2}$$

$n$ -ary forms  $\bigcap_i R_i / \bigcup_i R_i$  over a block family (`positiveCombination{And,Or,Inter,Union}_sound`); positive connectives only — negation rides the normal-form and closure machinery, never this rule.

QPOSITIVECOMBINATIONROOT assembles a certificate for a root boolean combination out of certificates for its blocks, at zero new row cost: if the children conclude  $\text{QRegionSat}(\varphi_1, R_1)$  and  $\text{QRegionSat}(\varphi_2, R_2)$ , the conjunction is certified on  $R_1 \cap R_2$  and the disjunction on  $R_1 \cup R_2$  — and the  $n$ -ary forms take  $\bigcap_i R_i$  and  $\bigcup_i R_i$  over a whole block family. A producer uses it at the top of every specification whose root is a positive boolean shape: each block is certified by its own sub-derivation (a battery, an invariance certificate, a nested combination), and the root costs two set operations.

What the checker recomputes: the region intersection or union itself. The semantic clauses — that the conjunction denotes the intersection of the denotations, the disjunction the union — enter as definitional bridges supplied by the specification layer, never as posted premises.

The word *positive* in the name is load-bearing. Under-approximation is preserved by intersection and union: a region inside each denotation is inside their intersection; a union of regions inside denotations is inside the union of the denotations. It is REVERSED by complement: the complement of an under-approximation over-approximates — the empty region under-approximates every denotation, and its complement, the whole space, over-approximates every complement. A negation passed through this rule would silently flip the judgment kind's one orientation guarantee. Negation therefore never passes through it; it rides the normal-form and closure machinery instead, where the direction swap is handled deliberately.

notes Admissible, not alias: several children and two lemma directions — more than a single application. The node shape (a pair of binary connective nodes versus one  $n$ -ary combination node) is an enactment decision still open on the schema side; the verified lemmas cover both forms, so neither choice waits on new mathematics.

### Lean statement

RegionSat is the compiled reading of the workhorse judgment kind — the region under-approximates the denotation — quoted in full because the four lemmas' meaning turns on it. The connective denotations enter through bridge hypotheses (`denAnd` = intersection of the children's denotations, `denOr` = union), supplied by the specification layer at compile time.

## Correspondence (Steele display ↔ Lean)

**reviewer-certified against the displayed texts** The dictionary below is a reviewer-certified statement of how the mechanized statements above interpret the displayed rule: display metavariable  $\mapsto$  Lean binder, each display hypothesis  $\mapsto$  the premise or side condition carrying it, the display conclusion  $\mapsto$  the goal — with any deliberate difference in width between display and mechanization named outright. Certification is recorded as a hash triple over (the displayed cell, the extracted statement texts, this dictionary's own text); if any of the three changes, this block turns amber until a reviewer re-certifies. The correspondence claim itself remains editorial — reviewer-grade, not machine-checked; its machine-checked successor types each soundness statement against the rule as a structured object, and supersedes this block per rule as it lands.

The judgment kind itself is bound by display:  $\text{RegionSat } R \text{ den} = R \subseteq \text{den}$  —  $\text{QRegionSat}$  compiled, the formula appearing only through its denotation (the System bridge, module §0). The two displayed binary rules  $\mapsto$  `positiveCombinationAnd_sound` / `Or_sound`: children  $\text{QRegionSat}(\varphi_i, R_i) \mapsto h_1/h_2 : \text{RegionSat } R_i \text{ den}_i$ ; conclusions at  $R_1 \cap R_2$  /  $R_1 \cup R_2$  verbatim; and the semantic clauses  $\llbracket \varphi_1 \wedge \varphi_2 \rrbracket = \llbracket \varphi_1 \rrbracket \cap \llbracket \varphi_2 \rrbracket$  (resp.  $\cup$ )  $\mapsto$  the bridge hypotheses  $\text{hbridge} : \text{denAnd} = \text{den}_1 \cap \text{den}_2$  — supplied by the future spec layer, never asserted in lean-aux, exactly as the roster witness says. The  $n$ -ary forms (`Inter_sound`/`Union_sound`, arbitrary index) cover the baked node shapes (`QAndRegion`/`QOrRegion`, each  $n$ -ary over a children list). Width note: pure lattice monotonicity over arbitrary sets — no formula grammar, no positivity syntax; the “positive connectives only” restriction is enforced by which bridges exist to supply (negation has no intersection/union clause), not by any binder here — refusal lives in the spec layer, the certified statements are the two monotone directions the display prices.

## Lean verifier receipts

module BernsteinLogicAux.Structural; bound build 1222cdcc326f... (bound from receipt cb0c3820c6877f22, 2026-07-29T01:03:36Z). A receipt records that named checking layers accepted a build: (module, compiled-artifact SHA-256, environment SHA-256, checker layers), minted when the checking gate ran; the store receipts attesting the bound build are listed with the layers each run credited. Nothing here asks the reader to trust the store: every layer is an independently runnable program over the quoted sources — rebuild the module and re-run the checkers to reproduce the verdict. Receipts attesting superseded builds credit no layer and are omitted from this rendering (the count of omissions, if any, is noted below).

| receipt          | minted               | layers                             | status  |

comparator: none no fixture in the three-implementation comparator harness (compiled / kernel-interpreted / reference-interpreted) exercises this rule.

## HOL4 statement

### NO HOL STATEMENT YET

The HOL4 development's object is the base calculus's wire-format checker (theory `bern_catalogue` ports the catalogue check-function cone). This rule concludes a satisfaction judgment of the extension theory: it postdates that port, and although the combination nodes are baked in the extension theory (`QAndRegion/QOrRegion`), no HOL development consumes the extension theory's rows — there is no ported check for a HOL statement to be about. The box becomes fillable when a checker consuming the extension's certificate rows is ported.

## HOL verifier receipts

### NONE

no HOL verification receipt exists for this rule.

## Proof

Genre: admissible rule (tier 2) — a proof-tree-rewriting recipe. Admissible and not alias by count: several children, and two lemma directions (one per connective). The rule adds zero sequent rows; its entire content is two one-line lattice-monotonicity facts about under-approximation.

The admissible template, general form, is stated once for the whole catalogue as Recipe [R16.1](#) of the `NORM` section; this section instantiates it.

**Recipe R62.1** (the `QPOSITIVECOMBINATIONROOT` instance).

$$\frac{\mathcal{T}_1 \triangleright \text{QRegionSat}(\varphi_1, R_1) \quad \mathcal{T}_2 \triangleright \text{QRegionSat}(\varphi_2, R_2)}{\mathcal{M}, x_0 \in R_1 \cap R_2 \models \varphi_1 \wedge \varphi_2} \wedge\text{-FORM} \quad \frac{\mathcal{T}_1 \triangleright \text{QRegionSat}(\varphi_1, R_1) \quad \mathcal{T}_2 \triangleright \text{QRegionSat}(\varphi_2, R_2)}{\mathcal{M}, x_0 \in R_1 \cup R_2 \models \varphi_1 \vee \varphi_2} \vee\text{-FORM}$$

Each node rewrites to its children — which stand unchanged — plus one application of the corresponding lattice-monotonicity warrant (Propositions [R62.2](#) and [R62.3](#)); the  $n$ -ary forms replace the pair by a family and the binary operation by  $\cap_i$  or  $\cup_i$ . No sequent row is added anywhere: the whole rewrite happens at the judgment layer.

**Proposition R62.2** (conjunction: intersection preserves under-approximation). *If  $R_1$  under-approximates the denotation of  $\varphi_1$  and  $R_2$  that of  $\varphi_2$ , then  $R_1 \cap R_2$  under-approximates the denotation of  $\varphi_1 \wedge \varphi_2$  (which is the intersection of the two denotations, by the specification layer's definitional clause).*

*Proof.*  $x \in R_1 \cap R_2$  gives  $x \in R_1 \subseteq \llbracket \varphi_1 \rrbracket$  and  $x \in R_2 \subseteq \llbracket \varphi_2 \rrbracket$ , so  $x \in \llbracket \varphi_1 \rrbracket \cap \llbracket \varphi_2 \rrbracket = \llbracket \varphi_1 \wedge \varphi_2 \rrbracket$ . One line (`positiveCombinationAnd_sound`); the final equality is the `denAnd` bridge, supplied at compile time, never posted.  $\square$

**Proposition R62.3** (disjunction: union preserves under-approximation). *Under the same hypotheses,  $R_1 \cup R_2$  under-approximates the denotation of  $\varphi_1 \vee \varphi_2$  (the union of the denotations).*

*Proof.*  $x \in R_1 \cup R_2$  lies in some  $R_j \subseteq \llbracket \varphi_j \rrbracket \subseteq \llbracket \varphi_1 \rrbracket \cup \llbracket \varphi_2 \rrbracket = \llbracket \varphi_1 \vee \varphi_2 \rrbracket$ . One line (`positiveCombinationOr_sound`), with the `denOr` bridge closing it.  $\square$

**Remark R62.4** (the  $n$ -ary forms, and the empty corners). The  $n$ -ary lemmas (`positiveCombinationInter_sound`, `positiveCombinationUnion_sound`) quantify over an arbitrary index type — no finiteness is consumed — so a single  $n$ -ary combination node brings no new mathematical idea beyond the same monotonicity principle; the  $n$ -ary lemmas themselves are its warrant (an arbitrary-index family is not a fold of binary steps, which is why they are separate statements). The empty corners are sound instances rather than exclusions: an empty conjunction denotes everything and  $\bigcap_{i \in \emptyset} R_i$  is the whole space, which under-approximates it; an empty disjunction denotes nothing and the empty union is empty, which under-approximates that. Neither degenerate certificate claims anything false, and each is worthless in its own honest way: the disjunction corner certifies the empty region, the conjunction corner certifies a tautology.

**Remark R62.5** (the polarity fence, with the two-line counterexample). Complement REVERSES the direction this rule preserves: from  $R \subseteq \llbracket \varphi \rrbracket$  nothing at all follows about `cmpl`  $R$  under-approximating `cmpl`  $\llbracket \varphi \rrbracket$  — the containment flips. Sharpest instance:  $R = \emptyset$  under-approximates every denotation, and its complement is the whole space, which under-approximates only the trivial one. A negation routed through this rule would silently convert the judgment kind's under-approximation guarantee into its opposite. The name *positive* is that fence: negation rides the normal-form rewrites and the closure discipline (the `QCLOSUREEXACT` section and its siblings), where the direction swap is handled deliberately, one atom at a time.

*Remark R62.6* (the bridge hypotheses). The semantic clauses  $\llbracket \varphi_1 \wedge \varphi_2 \rrbracket = \llbracket \varphi_1 \rrbracket \cap \llbracket \varphi_2 \rrbracket$  and its  $\vee$ /union twin enter the verified statements as named bridge hypotheses (`denAnd`, `denOr`), to be discharged definitionally by the specification layer's compile. The warrant deliberately does not assert them: what the connectives denote is the specification layer's to define, and this rule's content is only that under-approximation respects whatever lattice structure that definition induces.

## Rule 63. QCLOSUREEXACT (alias rule)

### The rule (Steele metanotation)

as realized in the mechanized development; source row: QTSL-rules.toml — *QClosureExact*. The metanotation statement is typeset by hand for notational quality; its mechanized ground truth is the Lean statement below, extracted from the sources at every build of this book and hash-bound. The rule *roster* is machine-checked (every mechanized rule tag round-trips to exactly one catalogue row); the statement *text* is editorial, checked by eye against the extracted Lean beside it.

$$\overline{\text{cml}\{p < c\}} = \{c \leq p\}$$

$$\overline{\text{cml}\{c < p\}} = \{p \leq c\}$$

two axioms — deduction rules with nothing above the line, each an exact set identity, both orientations stated (`closureExactLt_sound/Gt`) — no margin spent, no side condition; the closed form is a closed set for continuous observables (`closureExact_isClosed_ge/le`).

The closure discipline is the calculus's answer to strict inequalities: rows quantify over closed cells and certificates consume closed atoms, so strict literals —  $\{p < c\}$ ,  $\{c < p\}$  — never reach a row. Three moves resolve them, keyed to where the literal sits. *QCLOSUREEXACT*, this rule, is the free one: the *complement* of a strict literal is already a closed atom, exactly —  $\text{cml}\{p < c\} = \{c \leq p\}$  — so a complemented strict literal is replaced by its closed form with no loss, no margin, and no side condition. The sibling moves pay: *QCLOSUREOUTWARD* closes the complement of a *closed* atom by an orientation swap that over-approximates (the sound direction at negative positions), and *QCLOSUREINWARDEPS* closes a strict literal at a positive position by rounding inward a producer-chosen  $\varepsilon > 0$  (the sound direction there). This rule is the alias of the trio; the other two are admissible.

What the checker recomputes: nothing — the rewrite is a definitional set identity, stated in both orientations because both strict forms occur in the atom grammar. The closedness that names the move is a fact about continuous observables: the closed form is a preimage of a closed ray, and the calculus's observables are polynomials.

notes The identity spends no margin — contrast the sibling moves, which each pay in one currency (a boundary cut, or an  $\varepsilon$ -band). Like *QFULLDOMAINWEAKEN*, the alias's target is a verified identity rather than a catalogue node. The  $\varepsilon$ -accounting for the inward move travels as producer annotation data on the certificate, never as a rule.

### Lean statement

The strict atom enters through the named bridge hypothesis (`hbridge`) fixing its compiled sublevel reading; the closedness lemmas ask only continuity of the observable.

BernsteinLogicAux.Structural . `closureExactLt_sound`

statement bound

```
/-- **T13 EXACT**, '<'-orientation: the complement of '{p < c}' IS the
closed atom '{c ≤ p}' — no rounding, no margin spent. -/
theorem closureExactLt_sound (p : X → ℝ) (c : ℝ) (strictAtom : Set X)
  (hbridge : strictAtom = {x | p x < c}) :
  strictAtomᶜ = {x | c ≤ p x}
```

BernsteinLogicAux.Structural . `closureExactGt_sound`

statement bound

```
/-- **T13 EXACT**, '>'-orientation. -/
theorem closureExactGt_sound (p : X → ℝ) (c : ℝ) (strictAtom : Set X)
  (hbridge : strictAtom = {x | c < p x}) :
  strictAtomᶜ = {x | p x ≤ c}
```

BernsteinLogicAux.Structural . `closureExact_isClosed_ge`

statement bound

```
/-- The closedness that names the move: '{c ≤ p}' is closed for continuous
'p'. -/
theorem closureExact_isClosed_ge [TopologicalSpace X] {p : X → ℝ}

```

BernsteinLogicAux.Structural . `closureExact_isClosed_le`

statement bound

```
/-- Closedness, the other orientation: '{p ≤ c}' is closed for continuous
'p'. -/
theorem closureExact_isClosed_le [TopologicalSpace X] {p : X → ℝ}
  (hp : Continuous p) (c : ℝ) : IsClosed {x | p x ≤ c}
```

## Correspondence (Steele display $\leftrightarrow$ Lean)

**reviewer-certified against the displayed texts** The dictionary below is a reviewer-certified statement of how the mechanized statements above interpret the displayed rule: display metavariable  $\mapsto$  Lean binder, each display hypothesis  $\mapsto$  the premise or side condition carrying it, the display conclusion  $\mapsto$  the goal — with any deliberate difference in width between display and mechanization named outright. Certification is recorded as a hash triple over (the displayed cell, the extracted statement texts, this dictionary's own text); if any of the three changes, this block turns amber until a reviewer re-certifies. The correspondence claim itself remains editorial — reviewer-grade, not machine-checked; its machine-checked successor types each soundness statement against the rule as a structured object, and supersedes this block per rule as it lands.

Transcription-close, both orientations bound separately (the recorded one-sidedness lesson as bind structure):  $\text{cmpl}\{p < c\} = \{c \leq p\} \mapsto \text{closureExactLt\_sound}$ , whose goal is the set identity  $\text{strictAtom}^c = \{x \mid c \leq p\ x\}$  under the System-bridge equality  $\text{hbridge} : \text{strictAtom} = \{x \mid p\ x < c\}$ ; the  $>$ -orientation  $\mapsto \text{closureExactGt\_sound}$ . The closedness that names the move  $\mapsto \text{closureExact\_isClosed\_ge/\_le}$ , and their binder row carries the one consumed regularity fact: Continuous  $p$  — the observable's continuity, which for polynomial atoms is free downstream but is named here, plus the  $[\text{TopologicalSpace } X]$  instance those two lemmas alone need. Width note:  $p : X \rightarrow \mathbb{R}$  arbitrary — the polynomial atom grammar is erased, safe direction; the identity pair is margin-free and side-condition-free exactly as displayed (no hypothesis beyond the bridge), and no completeness claim exists to state — an identity loses nothing by construction.

## Lean verifier receipts

module BernsteinLogicAux.Structural; bound build 1222cdcc326f... (bound from receipt cb0c3820c6877f22, 2026-07-29T01:03:36Z). A receipt records that named checking layers accepted a build: (module, compiled-artifact SHA-256, environment SHA-256, checker layers), minted when the checking gate ran; the store receipts attesting the bound build are listed with the layers each run credited. Nothing here asks the reader to trust the store: every layer is an independently runnable program over the quoted sources — rebuild the module and re-run the checkers to reproduce the verdict. Receipts attesting superseded builds credit no layer and are omitted from this rendering (the count of omissions, if any, is noted below).

## HOL4 statement

### NO HOL STATEMENT YET

The HOL4 development's object is the base calculus's wire-format checker (theory `bern_catalogue` ports the catalogue check-function cone). The closure discipline is a specification-surface rewrite layer of the extension theory: it postdates that port, and no row for any of the three moves exists in the baked theory — there is nothing for a HOL statement to be about. The box becomes fillable when a revision carries the closure moves' certificate rows and the corresponding check is ported.

## HOL verifier receipts

### NONE

no HOL verification receipt exists for this rule.

## Proof

Genre: alias rule (tier 3) — a respelling template, here in the degenerate–target form: the target is a verified set identity, not a catalogue node. This section also carries the closure discipline's shared preamble; the `QCLOSUREOUTWARD` and `QCLOSUREINWARDEPS` sections build on it by reference.

**Recipe R63.1** (the closure discipline — shared preamble for the trio). The kernel's rows quantify over closed cells; its certificates consume closed atoms; its exact arithmetic decides non-strict comparisons. Strict literals therefore never reach a row: every strict atom is resolved, before rows are emitted, by one of three moves keyed to the literal's position.

| literal                        | move                                                               | cost                                                            |
|--------------------------------|--------------------------------------------------------------------|-----------------------------------------------------------------|
| complement of a strict atom    | <code>QCLOSUREEXACT</code> : replace by the closed form            | none (set identity)                                             |
| complement of a closed atom    | <code>QCLOSUREOUTWARD</code> : swap orientation, over-approximate  | the cut $\{p = c\}$                                             |
| strict atom, positive position | <code>QCLOSUREINWARDEPS</code> : round inward by $\varepsilon > 0$ | the band $(c - \varepsilon, c)$ ; mirror $(c, c + \varepsilon)$ |

The polarity logic: at a *positive* position — the atom contributes to what the certified region must lie inside — under-approximation is sound, so shrinking the atom (the inward move) is the safe direction. At a *negative* position — the atom arrives complemented — the consuming side wants the complement over-approximated, so growing it by the boundary cut (the outward move) is the safe direction. The exact move is direction-free: an identity is sound everywhere. Soundness-only is the discipline's contract: no move claims to preserve provability, and a specification tight at a critical threshold fails honestly — the certificate is refused — rather than being silently widened.

**Recipe R63.2** (the `QCLOSUREEXACT` instance).

$$\text{cmpl}\{p < c\} \rightsquigarrow \{c \leq p\} \qquad \text{cmpl}\{c < p\} \rightsquigarrow \{p \leq c\}$$

Payload transport: observable  $p$  and threshold  $c$  verbatim; orientation swapped; strictness dropped; the complement consumed. One literal  $\rightarrow$  one closed atom, and the respelling is *exact*: Proposition R63.3 is an equality, not a containment, so the rewrite is sound at every position, positive or negative — the only member of the trio with that property.

**Proposition R63.3** (the exactness identity).  $\text{cmpl}\{x \mid p(x) < c\} = \{x \mid c \leq p(x)\}$ , and symmetrically  $\text{cmpl}\{x \mid c < p(x)\} = \{x \mid p(x) \leq c\}$ .

*Proof.* Pointwise,  $\neg(p(x) < c) \iff c \leq p(x)$  — totality of the order on  $\mathbb{R}$ , nothing more. `closureExactLt_sound` and `closureExactGt_sound` are this equivalence under one set-extensionality step; there is no analytic content anywhere in the move.  $\square$

**Proposition R63.4** (the closedness that names the move). For continuous  $p$ , the atoms  $\{c \leq p\}$  and  $\{p \leq c\}$  are closed sets.

*Proof.* Each is the preimage under  $p$  of a closed ray (`closureExact_isClosed_ge`, `_le`). The calculus's observables are polynomials, hence continuous; the lemmas ask continuity only, so any continuous extension of the observable grammar inherits the move unchanged.  $\square$

**Remark R63.5** (both orientations, deliberately). The identity is stated twice because both strict forms occur in the atom grammar, and a one-sided statement of a complement lemma is a standing trap for author and porter alike. Stating both orientations costs two lines and removes the trap.

**Remark R63.6** (soundness corollary, and what the siblings inherit). Substituting equals for equals needs no direction analysis, so the soundness corollary is immediate: any judgment consuming  $\text{cmpl}\{p < c\}$  may consume  $\{c \leq p\}$  with identical denotation, and no margin is spent. The sibling moves are containments, not identities, and their soundness is position-dependent — which is exactly why the discipline routes each literal to the move whose direction its position wants (Recipe R63.1).

| proof step          | formal anchor                                                                 |
|---------------------|-------------------------------------------------------------------------------|
| Proposition R63.3   | <code>closureExactLt_sound</code> , <code>closureExactGt_sound</code>         |
| Proposition R63.4   | <code>closureExact_isClosed_ge</code> , <code>closureExact_isClosed_le</code> |
| strict-atom reading | the <code>hbridge</code> hypothesis of the identity lemmas                    |
| the sibling moves   | the <code>QCLOSUREOUTWARD</code> and <code>QCLOSUREINWARDEPS</code> sections  |

## Rule 64. QCLOSUREOUTWARD (admissible rule)

### The rule (Steele metanotation)

as realized in the mechanized development; source row: QTSL-rules.toml — *QClosureOutward*. The metanotation statement is typeset by hand for notational quality; its mechanized ground truth is the Lean statement below, extracted from the sources at every build of this book and hash-bound. The rule *roster* is machine-checked (every mechanized rule tag round-trips to exactly one catalogue row); the statement *text* is editorial, checked by eye against the extracted Lean beside it.

$$\frac{}{\text{cml}\{p \leq c\} \subseteq \{c \leq p\}} \qquad \frac{}{\text{cml}\{c \leq p\} \subseteq \{p \leq c\}} \qquad \frac{R \subseteq \llbracket \varphi \rrbracket}{\text{cml} \llbracket \varphi \rrbracket \subseteq \text{cml} R}$$

the closed swap over-approximates the true complement, losing only the cut  $\{p = c\}$  — the direction negative positions consume; atom face both orientations (*closureOutward\_sound/Ge*) + the antitone region face (*compl\_over\_approx*).

QCLOSUREOUTWARD is the closure discipline's move for complements of *closed* atoms (the discipline itself is set out in the QCLOSUREEXACT section). The true complement of  $\{p \leq c\}$  is the strict set  $\{c < p\}$  — not consumable by a row — and the move consumes the orientation swap  $\{c \leq p\}$  instead, which contains it: an over-approximation of the true complement, losing only the cut  $\{p = c\}$ . Over-approximation is exactly what the consuming side wants at negative positions: there the atom describes a set to be excluded or avoided, and a certificate against a superset is a fortiori a certificate against the set.

The warrant has two faces, both verified. The *atom* face is the pointwise containment above, in both orientations. The *region* face is the antitone kernel: a certified region under-approximates its denotation, so its complement over-approximates the denotation's complement — the direction transport that lets a negative position consume a child certificate's complement soundly. What the checker recomputes: the orientation swap itself, which is syntactic; the containments are the verified lemmas' content, spent once, globally.

The move is one-directional by design: at a *positive* position the same swap would overclaim — take  $p$  constant at  $c$ : the swap  $\{c \leq p\}$  is the whole space while the true complement of  $\{p \leq c\}$  is empty, the maximal over-claim — so the discipline's routing table, not a side condition, keeps this move on the negative side.

**notes** The conditional flag this entry once carried recorded the composite normal-form induction that pushes complements through connectives — deliberately outside this rule's own lemmas, since that induction is stated once, for all consumers, with the normal-form rewriting rules. It has since been mechanized where it lives, so the row carries no conditional flag: *denot\_nnf* (BernsteinLogicAux.NNFDuality, bound at the QSTREETTREQUESTNNF entry) is the denotation-preserving normal-form pass whose induction cases are exactly the QNNFREWRITE axioms, with *NForm.elimNeg* / *denot\_elimNeg* the consumption-boundary elimination. A reader tracing a complement through a full specification follows this rule for the atom step and the normal-form sections for the traversal; the composition-as-applied stays producer-side, which is why the traversal is cited here, not bound.

### Lean statement

RegionSat (quoted in full) is the compiled reading of the workhorse judgment kind, consumed by the region face; the atom faces fix the consumed closed swap through the bridge hypothesis (*hbridge*).

BernsteinLogicAux.Structural . **closureOutward\_sound**

statement bound

```
/-- **T13 OUTWARD**, `≤`-atom: the consumed closed swap `{c ≤ p}` contains
the true complement of `{p ≤ c}`. No margin is spent (the containment loses
only the measure-zero cut `{p = c}`). -/
theorem closureOutward_sound (p : X → ℝ) (c : ℝ) (cmlAtom : Set X)
  (hbridge : cmlAtom = {x | c ≤ p x}) :
  {x | p x ≤ c}ᶜ ⊆ cmlAtom
```

BernsteinLogicAux.Structural . **closureOutwardGe\_sound**

statement bound

```
/-- **T13 OUTWARD**, `≥`-atom orientation. -/
theorem closureOutwardGe_sound (p : X → ℝ) (c : ℝ) (cmlAtom : Set X)
  (hbridge : cmlAtom = {x | p x ≤ c}) :
  {x | c ≤ p x}ᶜ ⊆ cmlAtom
```

BernsteinLogicAux.Structural . **compl\_over\_approx**

statement bound

```
/-- The antitone region-complement kernel (region face): an
under-approximating certified region's complement OVER-approximates the
semantic complement — the direction negative positions consume. -/
theorem compl_over_approx {R den : Set X} (h : RegionSat R den) :
  denᶜ ⊆ Rᶜ
```

BernsteinLogicAux.Structural.RegionSat

definition bound

```

/-- The satisfaction judgment's workhorse kind, compiled: region `R`
under-approximates denotation `den`. -/
def RegionSat (R den : Set X) : Prop := R ≤ den

```

## Correspondence (Steele display ↔ Lean)

**reviewer-certified against the displayed texts** The dictionary below is a reviewer-certified statement of how the mechanized statements above interpret the displayed rule: display metavariable  $\mapsto$  Lean binder, each display hypothesis  $\mapsto$  the premise or side condition carrying it, the display conclusion  $\mapsto$  the goal — with any deliberate difference in width between display and mechanization named outright. Certification is recorded as a hash triple over (the displayed cell, the extracted statement texts, this dictionary's own text); if any of the three changes, this block turns amber until a reviewer re-certifies. The correspondence claim itself remains editorial — reviewer-grade, not machine-checked; its machine-checked successor types each soundness statement against the rule as a structured object, and supersedes this block per rule as it lands.

Three displayed clauses, three bound statements. The atom face, both orientations:  $\text{cmpl}\{p \leq c\} \subseteq \{c \leq p\} \mapsto \text{closureOutward\_sound}(\text{goal}\{x \mid p \ x \leq c\}^c \subseteq \text{cmplAtom under the bridge } \text{cmplAtom} = \{x \mid c \leq p \ x\})$ , mirrored by  $\text{closureOutwardGe\_sound}$  — containments, not identities: the flavor text's “losing only the cut  $\{p = c\}$ ” is commentary on the gap, and the certified statement claims exactly the over-approximation direction, nothing finer. The region face  $R \subseteq \llbracket \varphi \rrbracket \Rightarrow \text{cmpl}\llbracket \varphi \rrbracket \subseteq \text{cmpl } R \mapsto \text{cmpl\_over\_approx} : \text{den}^c \subseteq R^c$  from  $\text{RegionSat } R \text{ den}$  — the antitone kernel, the region face of the closure discipline, two tokens of proof. Width note: this row once carried a conditional mark for a composite residue — the De Morgan *traversal* of a full specification — which is discharged: the traversal lives with the  $\text{QNnfRewrite}/\text{QStreettRequestNnf}$  normal-form machinery, deliberately not here, and is machine-checked there ( $\text{denot\_nnf} + \text{denot\_elimNeg}$ , cross-cited in the note), so the row carries no conditional flag and what remains is only that division of binding responsibility. The certified atom + region faces are unconditional set-level facts over arbitrary observables and regions; no topology, no continuity, no polynomiality is consumed anywhere in this bound set.

## Lean verifier receipts

module BernsteinLogicAux.Structural; bound build 1222cdcc326f... (bound from receipt cb0c3820c6877f22, 2026-07-29T01:03:36Z). A receipt records that named checking layers accepted a build: (module, compiled-artifact SHA-256, environment SHA-256, checker layers), minted when the checking gate ran; the store receipts attesting the bound build are listed with the layers each run credited. Nothing here asks the reader to trust the store: every layer is an independently runnable program over the quoted sources — rebuild the module and re-run the checkers to reproduce the verdict. Receipts attesting superseded builds credit no layer and are omitted from this rendering (the count of omissions, if any, is noted below).

| receipt          | minted               | layers                             | status  |

## HOL4 statement

### NO HOL STATEMENT YET

The HOL4 development's object is the base calculus's wire-format checker (theory `bern_catalogue` ports the catalogue check-function cone). The closure discipline is a specification-surface rewrite layer of the extension theory: it postdates that port, and no row for any of the three moves exists in the baked theory — there is nothing for a HOL statement to be about. The box becomes fillable when a revision carries the closure moves' certificate rows and the corresponding check is ported.

## HOL verifier receipts

### NONE

no HOL verification receipt exists for this rule.

## Proof

Genre: admissible rule (tier 2) — a proof-tree-rewriting recipe. The closure discipline this move belongs to — why strict literals never reach a row, and how the three moves divide the positions — is set out in full in the QCLOSUREEXACT section; this section states only what is native to the outward move: the two verified faces of its warrant, and the direction analysis that confines it to negative positions.

The admissible template, general form, is stated once for the whole catalogue as Recipe R16.1 of the NORM section; this section instantiates it.

**Recipe R64.1** (the QCLOSUREOUTWARD instance — two faces). *Atom face.* At a negative position, the complement of a closed atom is consumed as its orientation swap:

$$\text{cmpl}\{p \leq c\} \rightsquigarrow \{c \leq p\} \qquad \text{cmpl}\{c \leq p\} \rightsquigarrow \{p \leq c\}$$

warranted by the containment  $\text{cmpl}\{p \leq c\} \subseteq \{c \leq p\}$  (Proposition R64.2): the consumed atom *over-approximates* the true complement, losing only the cut  $\{p = c\}$ .

*Region face.* A negative position consuming the complement of a *certified region*  $R$  (a child certificate's conclusion, not a syntactic atom) is warranted by the antitone kernel (Proposition R64.3): certified under-approximation of the denotation becomes over-approximation of the denotation's complement. Both faces discharge against their verified containment; the orientation swap itself is syntactic and recomputed by the checker.

**Proposition R64.2** (atom face).  $\text{cmpl}\{x \mid p(x) \leq c\} \subseteq \{x \mid c \leq p(x)\}$ , and symmetrically  $\text{cmpl}\{x \mid c \leq p(x)\} \subseteq \{x \mid p(x) \leq c\}$ .

*Proof.* If  $\neg(p(x) \leq c)$  then  $c < p(x)$ , hence  $c \leq p(x)$  — the strict fact weakened to its non-strict form (`closureOutward_sound`; the mirror is `closureOutwardGe_sound`). The two sides differ exactly by the cut  $\{p = c\}$ , which the swap adjoins.  $\square$

**Proposition R64.3** (region face — the antitone kernel). *If a certified region under-approximates a denotation,  $R \subseteq \llbracket \varphi \rrbracket$ , then  $\text{cmpl} \llbracket \varphi \rrbracket \subseteq \text{cmpl} R$ : the complement of the certificate over-approximates the complement of the denotation.*

*Proof.* Contrapositive, one line:  $x \notin \text{cmpl} R$  means  $x \in R \subseteq \llbracket \varphi \rrbracket$ , so  $x \notin \text{cmpl} \llbracket \varphi \rrbracket$  (`cmpl_over_approx`). This is the direction transport that lets negative positions consume child certificates at all: the judgment kind fixes one orientation, and complementation flips it in precisely the way the consuming side wants.  $\square$

**Remark R64.4** (what is lost, and why the direction is right). Only the cut  $\{p = c\}$  — and in the sound direction. At a negative position the atom names a set to be excluded or avoided; certifying against a superset of it is a fortiori certifying against it. The move never claims the cut is negligible — for a nondegenerate *polynomial* observable ( $p - c$  not identically zero on a full-dimensional cell) it is a measure-zero level set, but soundness nowhere consumes that: the containment alone carries the warrant, so even a degenerate observable whose cut is fat (at the extreme  $p \equiv c$ , the whole cell) only makes the certificate more conservative, never wrong.

**Remark R64.5** (one-directional by design). At a *positive* position the same swap would overclaim. Take  $p$  constant at  $c$ : the swap  $\{c \leq p\}$  is the whole space, while the true complement of  $\{p \leq c\}$  is empty — the maximal over-claim. Nothing in the move's own premises excludes this; the closure discipline's routing table (the preamble, QCLOSUREEXACT section) is the guard — the recipe's “at a negative position” names that routing assignment, not a premise the move checks for itself — sending positive-position strict literals to the inward move instead. A porter implementing the discipline ports the routing with it, or re-learns this remark the hard way.

**Remark R64.6** (what is deliberately not warranted here). The verified faces are the atom step and the region step. The composite induction — pushing complements through conjunctions, disjunctions, and nested operators until they reach atoms — is stated once, for all consumers, with the normal-form rewriting rules — this rule's warrant is deliberately partial in exactly that sense: a complement traversing a full specification rides the normal-form sections for the traversal and this rule for the atoms it arrives at.

### proof step

the closure-discipline preamble (QCLOSUREEXACT section)  
the normal-form rewriting sections (deliberately not this rule)

## Rule 65. QCLOSUREINWARD EPS (admissible rule)

### The rule (Steele metanotation)

as realized in the mechanized development; source row: QTSL-rules.toml — *QClosureInwardEps*. The metanotation statement is typeset by hand for notational quality; its mechanized ground truth is the Lean statement below, extracted from the sources at every build of this book and hash-bound. The rule *roster* is machine-checked (every mechanized rule tag round-trips to exactly one catalogue row); the statement *text* is editorial, checked by eye against the extracted Lean beside it.

$$\frac{\varepsilon \in \mathbb{Q}_{>0}}{\{p \leq c - \varepsilon\} \subseteq \{p < c\}} \qquad \frac{\varepsilon \in \mathbb{Q}_{>0}}{\{c + \varepsilon \leq p\} \subseteq \{c < p\}}$$

the producer-chosen  $\varepsilon$  elaborates a strict atom at a positive position to its rounded closed form ( $\{p < c\} \rightsquigarrow \{p \leq c - \varepsilon\}$ ,  $\{c < p\} \rightsquigarrow \{c + \varepsilon \leq p\}$ ), and the displayed containments are why that is sound: the rounded closed atom strengthens the claim (*closureInwardEpsLt\_sound/Gt*, any real  $\varepsilon > 0$  — rationality subsumed by cast); soundness-only, no completeness preservation claimed — the honest failure at a critical threshold is refusal. Closedness rider: *closureInwardEps\_isClosed*.

QCLOSUREINWARD EPS is the closure discipline's move for strict literals at positive positions (the discipline is set out in the QCLOSUREEXACT section): the literal  $\{p < c\}$  is replaced by the closed atom  $\{p \leq c - \varepsilon\}$  for a producer-chosen rational  $\varepsilon > 0$ . The rounded atom is contained in the literal, so at a position where the certified region must lie *inside* the denotation, the substitution strengthens the obligation — sound by construction — and hands the kernel a closed atom it can consume.

The  $\varepsilon$  is real spend: the band between  $c - \varepsilon$  and  $c$  is surrendered (between  $c$  and  $c + \varepsilon$  in the mirror orientation). The choice of  $\varepsilon$  lives in the producer toolkit — searchable, like a multiplier or a cover — and its accounting travels as annotation data on the certificate, not as a rule. What the checker recomputes: nothing beyond the rewritten atom; the containment is the verified lemma, spent once, globally.

The contract is soundness-only, and the honest failure mode is refusal: a specification exactly tight at its threshold — the intended witness satisfies  $p < c$  everywhere, but  $p$  approaches  $c$  on the region — admits no  $\varepsilon$ , and the certificate is refused rather than silently widened. No completeness preservation is claimed, deliberately.

notes The verified statement takes any real  $\varepsilon > 0$ ; the producer's  $\varepsilon$  being rational is a representation fact about certificates, subsumed by the cast — soundness for every positive real is a fortiori soundness for every positive rational. The closedness of the rounded atom is an instance of the exact move's closedness lemma at the shifted threshold.

### Lean statement

Both orientations of the rounding, plus the closedness rider; the rounded atom enters through the bridge hypothesis (*hbridge*) fixing its compiled sublevel reading, and  $\varepsilon$  enters as a real with  $0 < \varepsilon$  (rationality of the producer's choice is subsumed by the cast).

BernsteinLogicAux.Structural . *closureInwardEpsLt\_sound*

statement bound

```
/-- **T13 INWARD-EPS**, `<-orientation: `{p ≤ c - ε} ⊆ {p < c}` for any
`ε > 0`. Substituting the rounded closed atom at a positive position
strengthens the certified claim. -/
theorem closureInwardEpsLt_sound (p : X → ℝ) (c ε : ℝ) (hε : 0 < ε)
  (roundedAtom : Set X)
  (hbridge : roundedAtom = {x | p x ≤ c - ε}) :
  roundedAtom ⊆ {x | p x < c}
```

BernsteinLogicAux.Structural . *closureInwardEpsGt\_sound*

statement bound

```
/-- **T13 INWARD-EPS**, `>-orientation: `{c + ε ≤ p} ⊆ {c < p}`. -/
theorem closureInwardEpsGt_sound (p : X → ℝ) (c ε : ℝ) (hε : 0 < ε)
  (roundedAtom : Set X)
  (hbridge : roundedAtom = {x | c + ε ≤ p x}) :
  roundedAtom ⊆ {x | c < p x}
```

BernsteinLogicAux.Structural . *closureInwardEps\_isClosed*

statement bound

```
/-- The inward-rounding closedness rider: the rounded atom is closed
(instance of the EXACT move's closedness at the shifted threshold). -/
theorem closureInwardEps_isClosed [TopologicalSpace X] {p : X → ℝ}
  (hp : Continuous p) (c ε : ℝ) : IsClosed {x | p x ≤ c - ε}
```

## Correspondence (Steele display $\leftrightarrow$ Lean)

**reviewer-certified against the displayed texts** The dictionary below is a reviewer-certified statement of how the mechanized statements above interpret the displayed rule: display metavariable  $\mapsto$  Lean binder, each display hypothesis  $\mapsto$  the premise or side condition carrying it, the display conclusion  $\mapsto$  the goal — with any deliberate difference in width between display and mechanization named outright. Certification is recorded as a hash triple over (the displayed cell, the extracted statement texts, this dictionary's own text); if any of the three changes, this block turns amber until a reviewer re-certifies. The correspondence claim itself remains editorial — reviewer-grade, not machine-checked; its machine-checked successor types each soundness statement against the rule as a structured object, and supersedes this block per rule as it lands.

Both displayed containments bound, orientation for orientation:  $\{p \leq c - \varepsilon\} \subseteq \{p < c\} \mapsto \text{closureInwardEpsLt\_sound}$  (the rounded atom entering through the bridge  $\text{roundedAtom} = \{x \mid p \ x \leq c - \varepsilon\}$ , the strict margin as  $\text{hE} : 0 < \varepsilon$ ), and the  $>$ -orientation  $\mapsto \text{closureInwardEpsGt\_sound}$ ; the inward-rounding closedness rider (the rounded atom is closed)  $\mapsto \text{closureInwardEps\_isClosed}$  (continuity consumed there alone, the  $\text{QClosureExact}$  pattern). Two width facts, one per direction of the display: the certified statements take *any real*  $\varepsilon > 0$  where the display asks  $\varepsilon \in \mathbb{Q}_{>0}$  — producer rationality subsumed by cast, divergence D3, statement wider in the safe direction; and no completeness–preservation statement exists in the module — the flavor text's “soundness-only” is certified by absence, with total loss at a critical cut remaining the honest refusal mode, exactly as the ledger inherits it.

## Lean verifier receipts

module BernsteinLogicAux.Structural; bound build 1222cdcc326f... (bound from receipt cb0c3820c6877f22, 2026-07-29T01:03:36Z). A receipt records that named checking layers accepted a build: (module, compiled-artifact SHA-256, environment SHA-256, checker layers), minted when the checking gate ran; the store receipts attesting the bound build are listed with the layers each run credited. Nothing here asks the reader to trust the store: every layer is an independently runnable program over the quoted sources — rebuild the module and re-run the checkers to reproduce the verdict. Receipts attesting superseded builds credit no layer and are omitted from this rendering (the count of omissions, if any, is noted below).

## HOL4 statement

### NO HOL STATEMENT YET

The HOL4 development's object is the base calculus's wire-format checker (theory `bern_catalogue` ports the catalogue check-function cone). The closure discipline is a specification-surface rewrite layer of the extension theory: it postdates that port, and no row for any of the three moves exists in the baked theory — there is nothing for a HOL statement to be about. The box becomes fillable when a revision carries the closure moves' certificate rows and the corresponding check is ported.

## HOL verifier receipts

### NONE

no HOL verification receipt exists for this rule.

## Proof

Genre: admissible rule (tier 2) — a proof-tree-rewriting recipe. The closure discipline this move belongs to is set out in full in the `QCLOSUREEXACT` section; this section states what is native to the inward move: the rounding containment in both orientations, the closedness rider, and the two honesty clauses — strictness of  $\varepsilon > 0$ , and the deliberate absence of any completeness claim.

The admissible template, general form, is stated once for the whole catalogue as Recipe **R16.1** of the `NORM` section; this section instantiates it.

**Recipe R65.1** (the `QCLOSUREINWARDEPS` instance). At a positive position, a strict literal rounds inward by a producer-chosen  $\varepsilon > 0$ :

$$\{p < c\} \rightsquigarrow \{p \leq c - \varepsilon\} \qquad \{c < p\} \rightsquigarrow \{c + \varepsilon \leq p\}$$

warranted by the containment  $\{p \leq c - \varepsilon\} \subseteq \{p < c\}$  (Proposition **R65.2**): the rounded closed atom *strengthens* the certified claim, which is the sound direction where the certified region must lie inside the denotation. Payload transport: observable and threshold verbatim, threshold shifted by  $\varepsilon$ , strictness dropped; the  $\varepsilon$  itself travels as certificate annotation data, never as a rule premise.

**Proposition R65.2** (the rounding containment). *For every  $\varepsilon > 0$ :  $\{x \mid p(x) \leq c - \varepsilon\} \subseteq \{x \mid p(x) < c\}$ , and symmetrically  $\{x \mid c + \varepsilon \leq p(x)\} \subseteq \{x \mid c < p(x)\}$ .*

*Proof.*  $p(x) \leq c - \varepsilon < c$ , the second inequality because  $\varepsilon > 0$  — one line of linear arithmetic (`closureInwardEpsLt_sound`; mirror `closureInwardEpsGt_sound`). The verified statements take any *real*  $\varepsilon > 0$ ; the producer's  $\varepsilon$  being rational is a representation fact about certificates, subsumed by the cast.  $\square$

**Proposition R65.3** (closedness rider). *For continuous  $p$ , both rounded atoms are closed sets:  $\{p \leq c - \varepsilon\}$  and  $\{c + \varepsilon \leq p\}$ .*

*Proof.* An instance of the exact move's closedness at the shifted threshold  $c - \varepsilon$  (`closureInwardEps_isClosed`, one application of `closureExact_isClosed_le`); the mirrored orientation is  $\{c + \varepsilon \leq p\} = p^{-1}([c + \varepsilon, \infty))$ , closed by the same continuity — the exact move's  $\geq$ -orientation closedness at threshold  $c + \varepsilon$  (the cited binding covers the  $\leq$  orientation; the mirror discharges against the  $\geq$  twin). The move thus delivers exactly what the discipline asked of it: a closed atom the kernel can consume.  $\square$

**Remark R65.4** ( $\varepsilon > 0$  strictly — the boundary counterexample). At  $\varepsilon = 0$  the containment fails:  $\{p \leq c\}$  is not contained in  $\{p < c\}$ , and the failure can be total — take  $p$  constant at  $c$ : the un-rounded atom is the whole space while the literal is empty. The strict positivity of  $\varepsilon$  is therefore the whole rule, in the same sense that the sign row is half of `HYPMULTIPLIER`: remove it and the move manufactures the maximal over-claim from nothing.

**Remark R65.5** (soundness-only, and the refusal posture). No completeness preservation is claimed, deliberately. The  $\varepsilon$ -band is surrendered —  $(c - \varepsilon, c)$  in the first orientation,  $(c, c + \varepsilon)$  in the mirror — and a specification exactly tight at its threshold — the intended witness satisfies  $p < c$  everywhere while  $p$  approaches  $c$  on the region — admits no  $\varepsilon$  at all: every rounding excludes points the witness needs. The honest outcome is refusal (no certificate exists through this move), never silent widening; a producer meeting refusal here either finds slack elsewhere in the specification or reports the tightness, and the discipline's contract is that the checker is never the party doing the forgiving.

**Remark R65.6** (why not under a complement). Rounding an atom that will be complemented is doubly wrong as a discharge of *this* obligation: the complement of the rounded atom,  $\{c - \varepsilon < p\}$ , is strict again — the closedness goal is defeated, and the  $\varepsilon$  was spent for nothing. Complemented literals belong to the exact move (free, when the inner literal is strict) or the outward move (when the inner atom is closed); the routing table in the closure-discipline preamble (`QCLOSUREEXACT` section) assigns every case exactly one move, and the assignment is what makes the trio a discipline rather than three tricks.

## Rule 66. TAYLORBOUND (alias for PCONSTEXACT)

### The rule (Steele metanotation)

as realized in the mechanized development; source row: QTS�-rules.toml — *TaylorBound*. The metanotation statement is typeset by hand for notational quality; its mechanized ground truth is the Lean statement below, extracted from the sources at every build of this book and hash-bound. The rule *roster* is machine-checked (every mechanized rule tag round-trips to exactly one catalogue row); the statement *text* is editorial, checked by eye against the extracted Lean beside it.

$$\frac{q \in \mathbb{Q}; \quad \theta \in \mathbb{Q}_{>0}; \quad T \in \mathbb{N}; \quad n \in \mathbb{N} \quad q \leq \sum_{k \leq n} (\theta T)^k / k! \text{ holds under exact evaluation in } \mathbb{Q}}{\Phi \vdash q \leq \sum_{k \leq n} (\theta T)^k / k!} \text{ TAYLORBOUND}$$

one PCONSTEXACT application, displayed at the deadline battery's Taylor comparison — every term is wire-free (closed), so the comparison is decided by the verified closed evaluator; no QTS� sort exists and none is needed. The transcendental fact  $\sum_{k \leq n} (\theta T)^k / k! \leq e^{\theta T}$  belongs to the consuming lemma, never the checker: the checker never needs to know  $e$  exists.

TAYLORBOUND supplies the deadline battery's rational surrogate for a transcendental bound. The deadline rule's soundness argument wants  $q \leq e^{\theta T}$  for a producer-chosen rational  $q$ , with decay rate  $\theta \in \mathbb{Q}_{>0}$  and horizon  $T \in \mathbb{Q}_{\geq 0}$  from its payload: its concluded sublevel region  $\{V \leq (1-p)q\}$  grows with  $q$ , so the producer wants the sharpest  $q$  the arithmetic affords. No checker doing exact rational arithmetic can evaluate  $e^{\theta T}$ , and none needs to: the certificate posts the single wire-free comparison  $q \leq \sum_{k \leq n} (\theta T)^k / k!$  — a finite sum of rationals, checked in exact  $\mathbb{Q}$  — and the consuming lemma carries the enclosure  $\sum_{k \leq n} (\theta T)^k / k! \leq e^{\theta T}$  (nonnegative Taylor remainder at nonnegative argument), so  $q \leq e^{\theta T}$  follows without the checker ever knowing  $e$  exists. A producer picks the truncation order  $n$  and any convenient  $q$  at or below the partial sum.

What the checker recomputes is the target rule's entire check: exact closed evaluation of one comparison. No certificate ever carries a TAYLORBOUND node — no sort exists and none is needed; the producer emits the ground-fact row directly, and this row is the catalogue-level name for that elaboration.

What would break without each hypothesis: with rounded rather than exact evaluation,  $q$  could creep above the true partial sum and the surrogate above  $e^{\theta T}$ ; without wire-freedom the “constant” could depend on state and the enclosure is meaningless; and the sign condition  $\theta T \geq 0$  is load-bearing in the consuming lemma — at negative arguments the Taylor remainder alternates in sign and the enclosure direction fails at alternate truncation orders (the proof section carries the counterexample).

**notes** Deliberately *not* aliased onto the interval-enclosure rule: that would import witness-bracket machinery for a metatheory one-liner, and the enclosure rule today lives only in a separate reference-checker implementation besides. The seam this rule instantiates is a design invariant of the whole extension page: transcendental facts live in soundness lemmas (the Lean-side deadline lemma consumes the standard library's partial-sum-below-exponential fact), arithmetic lives in the checker. Mechanization state, plainly: the bound statements below are the enclosure and its exact- $\mathbb{Q}$  face. `taylorLeaf_le_exp` (module `BernsteinLogicAux.QtslAliases`) is the enclosure step —  $q$  at or below the truncated sum is below  $e^x$  at nonnegative argument, the nonnegative Taylor remainder — and `taylorLeaf_rat_le_exp` is the row end to end: the wire-free comparison exactly as the checker replays it, in  $\mathbb{Q}$ , with the  $(\theta, T)$  payload shape, concluding  $q \leq e^{\theta T}$ . The consuming site is `sound_QDeadlineBattery's hq` premise (the target's entry), whose internal enclosure step these statements name as a rule-level fact. The sign condition  $0 \leq \theta T$  is a stated hypothesis, exactly as load-bearing as the commentary's counterexample says it is. No profile enters; the entry carries no conditional flag. The target's comparator exclusion ( $\neq$  inadmissible) travels with the alias to any port.

### Lean statement

`BernsteinLogicAux.QtslAliases . taylorLeaf_le_exp`

statement bound

```
-- **The enclosure step** (QTS�-rules.toml row `TaylorBound (T7)`): a
-- producer-chosen `q` at or below the order-`n` Taylor partial sum of
-- `exp` at a nonnegative argument is below `exp` itself — the nonnegative
-- Taylor remainder (`Real.sum_le_exp_of_nonneg`). The sign condition
-- `0 ≤ x` is load-bearing: at negative arguments the remainder alternates
-- in sign, so the enclosure fails at alternate truncation orders (at
-- `x = -1` it fails at `n = 0`, since `1 > e⁻¹`, and holds at `n = 1`) —
-- there is no all-`n` enclosure to be had (counter-witnesses in the
-- book's proof section). -/
theorem taylorLeaf_le_exp {q x : ℝ} {n : ℕ} (hx : 0 ≤ x)
  (hq : q ≤ ∑ k ∈ range (n + 1), x ^ k / (Nat.factorial k : ℝ)) :
  q ≤ Real.exp x
```

`BernsteinLogicAux.QtslAliases . taylorLeaf_rat_le_exp`

statement bound

```

/-- **TaylorBound`, the exact- $\mathbb{Q}$  face, end to end** (rule row
`TaylorBound (T7)` – the single wire-free closed comparison, checked in
exact  $\mathbb{Q}$ , that stands in for ` $q \leq e^{\{0T\}}$ ): decay rate ` $\theta \in \mathbb{Q}_{\geq 0}$ ` and
horizon ` $T \in \mathbb{N}$ ` from the deadline payload, truncation order ` $n$ `
producer-chosen. The checker replays the hypothesis; the conclusion –
which mentions ` $e$ ` – lives only here (the catalogue's "the checker never
needs to know ` $e$ ` exists"). Consuming site: `sound_QDeadlineBattery`'s
`hq` premise. -/
theorem taylorLeaf_rat_le_exp {qq  $\theta$  :  $\mathbb{Q}$ } {T n :  $\mathbb{N}$ } (h $\theta$  :  $\theta \leq 0$ )
  (hleaf : qq  $\leq \sum k \in \text{range } (n + 1), (\theta * T) ^ k / (\text{Nat.factorial } k : \mathbb{Q})$ ) :
  (qq :  $\mathbb{R}$ )  $\leq \text{Real.exp } (\theta * T)$ 

```

The payload-level elaborator, displayed whole.  $(q, \theta, T, n)$  to the one PConstExact payload, the right side expanded producer-side in exact  $\mathbb{Q}$ ; the checker replays one closed comparison, and the transcendental conclusion appears only in `taylorElab_le_exp`'s goal.

BernsteinLogic.QtslElaborators . **taylorFormula\_true\_iff**

statement bound

```

/-- The wire-level replay identity: the checker's `true` verdict is
exactly the  $\mathbb{Q}$  comparison against the partial sum. -/
theorem taylorFormula_true_iff (q  $\theta$  : Rat) (T n : Nat) :
  (taylorFormula q  $\theta$  T n).evalClosed = some true  $\leftrightarrow q \leq \text{taylorPartialSum } \theta T n$ 

```

BernsteinLogic.QtslElaborators . **taylorElab\_sound**

statement bound

```

/-- The factoring, BL face: `sound_pConstExact` at the elaborated
payload (`prop:tb-sound`'s first half – validity of the posted
comparison at every valuation). -/
theorem taylorElab_sound {H : Hypernet} {seq : Sequent} {q  $\theta$  : Rat} {T n : Nat}
  (hEval : (taylorFormula q  $\theta$  T n).evalClosed = some true)
  (hpost : seq.post = taylorFormula q  $\theta$  T n) :
  seq.semanticallyValid H

```

BernsteinLogic.QtslElaborators . **taylorElab\_le\_exp**

statement bound

```

/-- The semantic face, end to end (`prop:tb-sound` composed with
`prop:tb-enclosure`): the checked wire comparison bounds ` $q$ ` by
`e^{\{0T\}}` through the bound enclosure – the elaborator factoring through
the kernel replay into `taylorLeaf_rat_le_exp`. The sign condition
` $\theta \leq 0$ ` is load-bearing (the proof section's negative-argument
counterexample); the deadline rule's typing supplies it. -/
theorem taylorElab_le_exp {q  $\theta$  : Rat} {T n : Nat} (h $\theta$  :  $\theta \leq 0$ )
  (hEval : (taylorFormula q  $\theta$  T n).evalClosed = some true) :
  (q :  $\mathbb{R}$ )  $\leq \text{Real.exp } (\theta * T)$ 

```

BernsteinLogic.QtslElaborators . **taylorPartialSum**

definition bound

```

/-- The order- $n$  Taylor partial sum of ` $\text{exp } (\theta * T)$ `, computed in exact
 $\mathbb{Q}$  – the producer-side expansion of `rec:tb-transport`'s right side. -/
def taylorPartialSum ( $\theta$  : Rat) (T n : Nat) : Rat :=
   $\sum k \in \text{Finset.range } (n + 1), (\theta * (T : \text{Rat})) ^ k / (\text{Nat.factorial } k : \text{Rat})$ 

```

BernsteinLogic.QtslElaborators . **taylorElab**

definition bound

```

/-- **The TaylorBound payload elaborator** (`rec:tb-transport`): (q,  $\theta$ ,
T, n) plus the checked comparison, to the one `PConstExactData`
inhabitant. No `TaylorBound` node sort exists and none is needed
(`rec:tb-template`) – this function is the catalogue-level name for the
producer's elaboration, mechanized. -/
def taylorElab (H : Hypernet) (seq : Sequent) (q  $\theta$  : Rat) (T n : Nat)
  (hEval : (taylorFormula q  $\theta$  T n).evalClosed = some true)
  (hpost : seq.post = taylorFormula q  $\theta$  T n) :
  PConstExactData H seq :=
  .mk H seq (.const q) (.const (taylorPartialSum  $\theta$  T n)) .le (by decide)
  hEval hpost

```

## Correspondence (Steele display $\leftrightarrow$ Lean)

**reviewer-certified against the displayed texts** The dictionary below is a reviewer-certified statement of how the mechanized statements above interpret the displayed rule: display metavariable  $\mapsto$  Lean binder, each display hypothesis  $\mapsto$  the premise or side condition carrying it, the display conclusion  $\mapsto$  the goal — with any deliberate difference in width between display and mechanization named outright. Certification is recorded as a hash triple over (the displayed cell, the extracted statement texts, this dictionary's own text); if any of the three changes, this block turns amber until a reviewer re-certifies. The correspondence claim itself remains editorial — reviewer-grade, not machine-checked; its machine-checked successor types each soundness statement against the rule as a structured object, and supersedes this block per rule as it lands.

The displayed wire-free comparison  $q \leq \sum_{k \leq n} (\theta T)^k / k!$  standing in for  $q \leq e^{\theta T} \mapsto$  the bound pair: `taylorLeaf_le_exp` (the enclosure step — partial sum below `Real.exp` at nonnegative argument, the `nonneg-remainder` citation) and `taylorLeaf_rat_le_exp`, the end-to-end exact- $\mathbb{Q}$  face: `qq`  $\theta : \mathbb{Q}, T : \mathbb{N}$ , hypothesis the exact- $\mathbb{Q}$  partial-sum comparison the checker replays, conclusion  $(qq : \mathbb{R}) \leq \text{Real.exp } (\theta * T)$  — the flavor text's “the checker never needs to know  $e$  exists” as a binder fact:  $e$  appears in the goal alone, never in a hypothesis. The sign condition  $\mapsto$  `h0`  $\theta \leq 0$  (load-bearing — the alternating-remainder counterexample in the proof section is why the binder exists); the truncation order  $n$  is producer-chosen, unconstrained. Width note: the consuming site (`sound_QDeadlineBattery`'s `hq` premise) is cited, not bound here — correct package-boundary behaviour, the deadline battery's own entry carries it; the displayed horizon  $T \in \mathbb{N}$  matches the bound end-to-end lemma's  $T : \mathbb{N}$  exactly (the rational-horizon generalization is mathematically available from `taylorLeaf_le_exp` but is neither bound nor displayed); and the displayed  $\theta \in \mathbb{Q}_{>0}$  is a deliberately stronger surface restriction than the bound `h0`  $\theta \leq 0$  — safe direction, the deadline battery's own decay-rate positivity.

### Lean verifier receipts

module `BernsteinLogicAux.QtslAliases`; bound build 570599779c29... (bound from receipt 5a60f4d01fd81ac5, 2026-07-21T05:39:02Z). A receipt records that named checking layers accepted a build: (module, compiled-artifact SHA-256, environment SHA-256, checker layers), minted when the checking gate ran; the store receipts attesting the bound build are listed with the layers each run credited. Nothing here asks the reader to trust the store: every layer is an independently runnable program over the quoted sources — rebuild the module and re-run the checkers to reproduce the verdict. Receipts attesting superseded builds credit no layer and are omitted from this rendering (the count of omissions, if any, is noted below).

**comparator: none** no fixture in the three-implementation comparator harness (compiled / kernel-interpreted / reference-interpreted) exercises this rule.

### HOL4 statement

#### OUT OF SCOPE BY DESIGN

Out of scope for the HOL side *by design*, not by backlog: the wire format never carries a `TAYLORBOUND` node (no sort exists and none is needed — the producer emits the ground-fact comparison row directly), so no wire certificate a HOL checker reads could ever contain one; HOL coverage for this rule *is* the target rule's. Today even that statement is not writable: the HOL4 development (theory `bern_catalogue`, the base catalogue's check-function cone) predates `PCONSTEXACT`, whose wire tag is unallocated — see that rule's section for the honest state of the target's own box.

### HOL verifier receipts

**NONE**

no HOL verification receipt exists for this rule.

**Proof**

Genre: alias rule (tier 3) — a respelling template. The five artefacts an alias owes the book: the 1→1 unpack, the filled-in target application, the payload-transport table, the exactness identity, and the soundness corollary through the target's lemma. All five follow, with one honest asymmetry marked where it occurs: this rule's exactness identity is not a ring identity but an *enclosure* — the Taylor-remainder inequality — and it lives in the consuming lemma, never in the checker. Mechanization state: the target's lemma is kernel-verified; the alias-level semantic content — the enclosure and its exact- $\mathbb{Q}$  face — is mechanized and bound in the entry, and so — now that the extension certificate schema exists — is the payload-level elaborator (the remark below names the bound functions).

**Recipe R66.1** (the template instance — no node sort, by design). The deadline rule (QDEADLINEBATTERY) wants the fact  $q \leq e^{\theta T}$  for a producer-chosen rational surrogate  $q$ , with decay rate  $\theta \in \mathbb{Q}_{>0}$  and horizon  $T \in \mathbb{Q}_{\geq 0}$  from its payload: its concluded sublevel region  $\{V \leq (1-p)q\}$  grows with  $q$ , so the producer wants the sharpest  $q$  the arithmetic affords. No checker doing exact rational arithmetic can evaluate  $e^{\theta T}$ , and none needs to: the certificate posts the single wire-free comparison

$$q \leq \sum_{k \leq n} (\theta T)^k / k!$$

for a producer-chosen truncation order  $n$  — a finite sum of rationals, one closed comparison — and the consuming lemma carries the enclosure to  $e^{\theta T}$  (Proposition R66.4). The unpack image is a single PCONSTEXACT node; indeed no TAYLORBOUND node sort exists and none is needed — the producer emits the ground-fact row directly, and this rule is the catalogue-level name for that elaboration. One node → one node, nothing derived.

**Recipe R66.2** (the filled-in application).

$$\frac{q \leq \sum_{k \leq n} (\theta T)^k / k! \text{ holds under exact evaluation in } \mathbb{Q}}{\Phi \vdash q \leq \sum_{k \leq n} (\theta T)^k / k!} \text{ PCONSTEXACT}$$

with arbitrary premise  $\Phi$ , as the target licenses (the rule is premise-free). Both sides are closed rational terms — the sum is finite, every summand exact — so the target's verified evaluator decides the comparison in exact  $\mathbb{Q}$ , and the comparator ( $\leq$ ) lies inside the target's admissible comparator set.

**Recipe R66.3** (payload transport — field for field).

| TAYLORBOUND data                      | PCONSTEXACT payload                                                         |
|---------------------------------------|-----------------------------------------------------------------------------|
| $q$ (the rational surrogate)          | left side of the comparison                                                 |
| $\theta, T, n$ (rate, horizon, order) | the right side $\sum_{k \leq n} (\theta T)^k / k!$ , expanded producer-side |
| comparator                            | $\leq$ (inside the admissible set)                                          |
| wire-freedom                          | implied, not declared: the evaluator returns none on any wire               |

The checker sees one closed comparison and nothing else;  $\theta$ ,  $T$ , and  $n$  survive only through the value of the right-hand term. The transcendental target  $e^{\theta T}$  appears in *no* field — that is the point.

**Proposition R66.4** (the enclosure — the exactness identity, honest form). *For  $\theta T \geq 0$  and any  $n$ ,*

$$\sum_{k \leq n} (\theta T)^k / k! \leq e^{\theta T}, \quad \text{hence} \quad q \leq \sum_{k \leq n} (\theta T)^k / k! \Rightarrow q \leq e^{\theta T}.$$

*Proof.* Two lines, though of a different species than a ring identity: at  $x := \theta T \geq 0$  every term of the exponential series is nonnegative, so each partial sum is dominated by the limit — in the classical Taylor form,  $e^x = \sum_{k \leq n} x^k / k! + R_n$  with the Lagrange remainder  $R_n = e^\xi x^{n+1} / (n+1)! \geq 0$  for some  $\xi \in [0, x]$  [214]. The sign condition is load-bearing: at negative arguments the remainder alternates in sign and the enclosure direction fails at alternate truncation orders ( $n=0$ ,  $x=-1$ : the partial sum is  $1 > e^{-1}$ ; at  $n=1$  it happens to hold again — there is no all- $n$  enclosure to be had) — the deadline rule's typing ( $\theta > 0$ ,  $T \geq 0$ ) is what entitles the lemma to the inequality, via  $\theta T \geq 0$ . Unlike the base-calculus exemplar alias, whose two-line identity is checked by the kernel as exact polynomial arithmetic, this identity is consumed *inside the deadline rule's soundness lemma* (the Lean side consumes the standard library's partial-sum-below-exponential fact, `Real.sum_le_exp_of_nonneg`, there) and never reaches the checker: the checker's whole obligation is the exact rational comparison of Recipe R66.2. The checker never needs to know  $e$  exists.  $\square$

**Proposition R66.5** (soundness corollary). *If the posted comparison checks and  $\theta T \geq 0$  (the sign hypothesis of Proposition R66.4), then  $q \leq e^{\theta T}$ , which is the fact the deadline rule's lemma consumes.*

*Proof.* `sound_pConstExact` (the target's kernel-verified lemma, quoted in the PCONSTEXACT section) turns the true evaluation into the validity of  $q \leq \sum_{k \leq n} (\theta T)^k / k!$  at every valuation; Proposition R66.4 extends to  $e^{\theta T}$  inside the consuming lemma. There is no other content — the alias genre working as intended.  $\square$

**Remark R66.6** (the payload-level elaborator, mechanized). The *semantic* content of the respelling is bound in the entry: `taylorLeaf_le_exp` is Proposition R66.4's enclosure step, and `taylorLeaf_rat_le_exp` is Proposition R66.5's exact- $\mathbb{Q}$  face end to end. The payload-level elaborator — previously this page's one absent artefact, held back until the extension certificate

schema existed — is bound with it: `taylorElab` (module `BernsteinLogic.QtsLElaborators`) takes  $(q, \theta, T, n)$  to exactly the one `PConstExact` payload of Recipe [R66.3](#), the right side expanded producer-side in exact  $\mathbb{Q}$  (`taylorPartialSum`), as an inhabitant of the target's own payload type — the comparator confinement discharged at elaboration, once — with `taylorElab_sound` the factoring through `sound_pConstExact`, `taylorFormula_true_iff` the wire-level replay identity, and `taylorElab_le_exp` the semantic face end to end (the checked comparison bounding  $q$  by  $e^{\theta T}$  through the bound enclosure — the transcendental conclusion still appears in no field, only in the goal). Stated at the discrete horizon,  $T : \mathbb{N}$ , matching the bound exact- $\mathbb{Q}$  face — the entry's width note carries the divergence from the recipe's rational-time payload; the enclosure of Proposition [R66.4](#) itself needs only  $\theta T \geq 0$ .

*Remark R66.7* (deliberately not an enclosure-rule alias). The calculus also has interval-enclosure machinery with witness brackets. Respelling this leaf onto it was considered and declined: that would import witness-bracket payload for a metatheory one-liner, and the enclosure rule today lives only in a separate reference-checker implementation besides. The seam this rule instantiates is a design invariant of the whole extension page: transcendental facts live in soundness lemmas, arithmetic lives in the checker.

*Remark R66.8* (the inherited comparator confinement). `PConstExact` excludes one comparator ( $\neq$ ) from its admissible set, for reasons of a second soundness invariant unpacked in that rule's section. This leaf uses  $\leq$  only — comfortably inside — but any port or mechanization of this rule must *preserve* the exclusion rather than re-derive the comparator set from the semantic lemma alone; the flag travels with the alias.

| proof step                                                | formal anchor                                                                                                                                                                                                                                    |

## Rule 67. ROOTEval (alias for PConstExact)

### The rule (Steele metanotation)

as realized in the mechanized development; source row: QTSL-rules.toml — *RootEval*. The metanotation statement is typeset by hand for notational quality; its mechanized ground truth is the Lean statement below, extracted from the sources at every build of this book and hash-bound. The rule *roster* is machine-checked (every mechanized rule tag round-trips to exactly one catalogue row); the statement *text* is editorial, checked by eye against the extracted Lean beside it.

$$\frac{R = \{x : V(x) \leq y\} \text{ (sublevel root atom)} \quad \vdash V(x_0) \leq y \text{ (one PConstExact leaf: the substituted comparison is closed)}}{\vdash x_0 \in R}$$

$$\frac{R = \prod_i [a_i, b_i] \text{ (box root atom)} \quad \forall i. a_i \leq (x_0)_i \leq b_i \text{ (recomputed in exact } \mathbb{Q})}{\vdash x_0 \in R}$$

catalogued as the eval leaf of the region-to-satisfaction bridge (a BL Proof leaf; the bridge's node sort is out of scope of the current baked theory — its baked warrant seam is `qsat_warrant`); sublevel atoms discharge through PConstExact (the first form is that rule's application at the substituted point), box atoms through the registry interval check (the second form: conformance recomputation, not a rule application).

ROOTEval is the membership leaf itself, catalogued as a rule of its own because every initialized certificate ends with one: membership of the specification's initial point in the *root atom* — the region atom concluded at the certificate's root (“root” names the certificate's root claim, not roots of polynomials) — by exact rational evaluation. In the certificate schema it is not a node sort at all: it is the eval leaf of the region-to-satisfaction bridge (QSatFromRegion — whose own node sort is out of scope of the current baked theory; the baked warrant seam is `qsat_warrant`), a base-proof leaf. For a sublevel atom  $\{x : V(x) \leq y\}$  the leaf is one PConstExact application: substitute the rational point into the polynomial — exact, no rounding anywhere — and decide one closed comparison. For a box atom, the checker recomputes per-coordinate containment directly (the side-condition registry: conformance recomputation, not a rule application).

What the checker recomputes: everything — the leaf *is* a recompute; there is no payload beyond the point and the atom. What would break without exactness: under naive (non-directed) rounding a point lying  $\varepsilon$  outside the region could certify membership, and the bridge rule would conclude satisfaction from a false premise — directed outward rounding keeps that direction sound but surrenders the equivalence at the boundary — the exactness identity in the proof section is a literal identity of values, and it is the whole rule. The comparator exclusion inherited from the target ( $\neq$  inadmissible, a second-soundness-invariant exclusion unpacked in the target's section) must survive any port.

**notes** The judgment-level composition — how the checked leaf feeds the instantiation that concludes root satisfaction — lives in the QSatFromRegion section; this row owns the leaf. Mechanization state, plainly: the bound statements below are the exactness identity itself. `rootEval_eval_cast` (module `BernsteinLogicAux.QtslAliases`) is the literal identity of values — evaluating the  $\mathbb{Q}$ -coefficient polynomial at the rational point and casting equals evaluating the cast polynomial at the cast point — and `rootEval_sublevel_iff` / `rootEval_box_iff` are its two atom shapes, each an *equivalence*: the exact- $\mathbb{Q}$  comparison decides the real-semantics membership in both directions, which is precisely the content a rounded evaluator would lose. The statements are over the generic polynomial-evaluation vocabulary (`MvPolynomial` over  $\mathbb{Q}$ , cast to  $\mathbb{R}$ ); the wire-term evaluator that produces the  $\mathbb{Q}$ -comparison is the target's own kernel-verified theorem, quoted in the PConstExact section, and the box-atom branch's registry recompute is checker-side by design. No profile enters; the entry carries no conditional flag.

### Lean statement

`BernsteinLogicAux.QtslAliases . rootEval_eval_cast`

statement bound

```
/-- **The exactness identity** (QTSL-rules.toml row `RootEval (T19)` – “a
literal identity of values, and it is the whole rule”): evaluating a
 $\mathbb{Q}$ -coefficient polynomial at a rational point and casting the result equals
evaluating the cast polynomial at the cast point. This is why the checker's
exact rational arithmetic (`PConstExact`'s replay) is the real-semantics
evaluation, with no rounding gap anywhere. -/
theorem rootEval_eval_cast {σ : Type*} (P : MvPolynomial σ  $\mathbb{Q}$ ) (xq : σ →  $\mathbb{Q}$ ) :
  ((MvPolynomial.eval xq P :  $\mathbb{Q}$ ) :  $\mathbb{R}$ )
    = MvPolynomial.eval (fun i => (xq i :  $\mathbb{R}$ )) (MvPolynomial.map (Rat.castHom  $\mathbb{R}$ ) P)
```

`BernsteinLogicAux.QtslAliases . rootEval_sublevel_iff`

statement bound

```
/-- **`RootEval`, sublevel atom, as an equivalence**: the exact  $\mathbb{Q}$  comparison
at the initial point decides membership of the cast point in the cast
```

```

sublevel atom `{x : V(x) ≤ thr}` – both directions, which is the content a
rounded evaluator would lose (one direction would survive rounding; the
identity does not). The forward direction is the leaf as the checker
discharges it (rule row `RootEval (T19)`, sublevel branch →
`PConstExact`). -/
theorem rootEval_sublevel_iff {σ : Type*} (P : MvPolynomial σ ℚ) (xq : σ → ℚ)
  (thr : ℚ) :
  MvPolynomial.eval xq P ≤ thr
  ↔ MvPolynomial.eval (fun i => (xq i : ℝ))
    (MvPolynomial.map (Rat.castHom ℝ) P) ≤ (thr : ℝ)

```

BernsteinLogic.QtslAliases . **rootEval\_box\_iff**

statement bound

```

/-- **`RootEval`, box atom, as an equivalence**: per-coordinate exact ℚ
containment decides containment of the cast point in the cast box (rule row
`RootEval (T19)`, box branch – the side-condition registry's per-coordinate
recompute). -/
theorem rootEval_box_iff {ι : Type*} (aq bq xq : ι → ℚ) :
  (∀ i, aq i ≤ xq i ∧ xq i ≤ bq i)
  ↔ ∀ i, ((aq i : ℝ) ≤ (xq i : ℝ) ∧ (xq i : ℝ) ≤ (bq i : ℝ))

```

**The payload-level elaborator, displayed whole.** The closed left-hand term is built by verified substitution (polyClosedTerm; its evaluation lemma says the checker's exact replay computes the value  $V(x_0)$  itself), and the elaborated payload inhabits the target's own payload type — comparator confinement discharged at elaboration.

BernsteinLogic.QtslElaborators . **polyClosedTerm\_evalQ**

statement bound

```

@[simp] theorem polyClosedTerm_evalQ (x0 : Nat → Rat) :
  ∀ p : Poly, (polyClosedTerm x0 p).evalQ? = some (Poly.eval x0 p)
| [] => by simp [polyClosedTerm, Poly.eval, Term.evalQ?]
| mc :: rest => by
  have ih

```

BernsteinLogic.QtslElaborators . **rootEvalFormula\_true\_iff**

statement bound

```

/-- The wire-level exactness identity, ℚ face (`prop:re-exact` at the
payload: the checker's `true` verdict IS the exact membership
inequality – both directions; the ℝ face stays
`Aliases.rootEval_sublevel_iff`). -/
theorem rootEvalFormula_true_iff (x0 : Nat → Rat) (V : Poly) (thr : Rat) :
  (rootEvalFormula x0 V thr).evalClosed = some true ↔ Poly.eval x0 V ≤ thr

```

BernsteinLogic.QtslElaborators . **rootEvalElab\_sound**

statement bound

```

/-- The factoring, BL face: the elaborated payload is sound through the
target's kernel-verified lemma – one application of
`sound_pConstExact`, which is itself one step to
`Formula.holds_of_evalClosed_true` (`prop:re-sound`). -/
theorem rootEvalElab_sound {H : Hypernet} {seq : Sequent} {x0 : Nat → Rat}
  {V : Poly} {thr : Rat}
  (hEval : (rootEvalFormula x0 V thr).evalClosed = some true)
  (hpost : seq.post = rootEvalFormula x0 V thr) :
  seq.semanticallyValid H

```

BernsteinLogic.QtslElaborators . **polyClosedTerm**

definition bound

```

/-- The closed polynomial term at a rational point. Wire-free by
construction, and its exact evaluation is `Poly.eval` at that point
(`polyClosedTerm_evalQ`) – the checker computes the value `V(x_0)`
itself, not an approximation to it. -/
def polyClosedTerm (x0 : Nat → Rat) (p : Poly) : Term :=
  p.foldr (fun mc acc => .add (.mul (.const mc.2) (monoClosedTerm x0 mc.1)) acc)
    (.const 0)

```

BernsteinLogic.QtslElaborators . **rootEvalFormula**

definition bound

```

/-- The elaborated leaf formula:  $\forall(x_0) \leq \text{thr}$  as one closed exact
comparison. -/
def rootEvalFormula (x0 : Nat → Rat) (V : Poly) (thr : Rat) : Formula :=
  .atom .le (polyClosedTerm x0 V) (.const thr)

```

BernsteinLogic.QtslElaborators . **rootEvalElab**

definition bound

```

/-- **The RootEval payload elaborator** (`rec:re-transport`, sublevel
branch): the alias's data – point, atom – plus its own checked leaf, to
the one `PConstExactData` inhabitant. The comparator confinement
travels by construction (`le ≠ .ne` discharged here, once). -/
def rootEvalElab (H : Hypernet) (seq : Sequent) (x0 : Nat → Rat) (V : Poly)
  (thr : Rat)
  (hEval : (rootEvalFormula x0 V thr).evalClosed = some true)
  (hpost : seq.post = rootEvalFormula x0 V thr) :
  PConstExactData H seq :=
  .mk H seq (polyClosedTerm x0 V) (.const thr) .le (by decide) hEval hpost

```

## Correspondence (Steele display ↔ Lean)

**reviewer-certified against the displayed texts** The dictionary below is a reviewer-certified statement of how the mechanized statements above interpret the displayed rule: display metavariable  $\mapsto$  Lean binder, each display hypothesis  $\mapsto$  the premise or side condition carrying it, the display conclusion  $\mapsto$  the goal — with any deliberate difference in width between display and mechanization named outright. Certification is recorded as a hash triple over (the displayed cell, the extracted statement texts, this dictionary's own text); if any of the three changes, this block turns amber until a reviewer re-certifies. The correspondence claim itself remains editorial — reviewer-grade, not machine-checked; its machine-checked successor types each soundness statement against the rule as a structured object, and supersedes this block per rule as it lands.

The displayed leaf rules — exact rational evaluation concluding root-atom membership, one form per atom shape —  $\mapsto$  three statements, and the strength gradation is the dictionary's content. `rootEval_eval_cast` is the literal identity of values:  $\mathbb{Q}$ -evaluation, cast, equals  $\mathbb{R}$ -evaluation of the cast polynomial at the cast point (MvPolynomial over any variable type — dimension-free). The two atom shapes are then *equivalences*, not implications: `rootEval_sublevel_iff` (exact- $\mathbb{Q}$  comparison  $\leftrightarrow$  membership in the cast sublevel atom) and `rootEval_box_iff` (per-coordinate  $\mathbb{Q}$  containment  $\leftrightarrow$  cast-box membership) — two-directional exactness, which is precisely what a rounded evaluator would lose (under directed outward rounding the sound forward direction survives and the iff does not; undirected rounding loses even soundness); the entry's “no rounding gap anywhere” as bind structure. Width note: the checker consumes only the forward directions (leaf discharge via `PConstExact` / the registry interval recompute); the certified equivalences are strictly stronger, safe direction, and no profile, measure, or topology enters any binder.

## Lean verifier receipts

module BernsteinLogicAux.QtslAliases; bound build 570599779c29... (bound from receipt 5a60f4d01fd81ac5, 2026-07-21T05:39:02Z). A receipt records that named checking layers accepted a build: (module, compiled-artifact SHA-256, environment SHA-256, checker layers), minted when the checking gate ran; the store receipts attesting the bound build are listed with the layers each run credited. Nothing here asks the reader to trust the store: every layer is an independently runnable program over the quoted sources — rebuild the module and re-run the checkers to reproduce the verdict. Receipts attesting superseded builds credit no layer and are omitted from this rendering (the count of omissions, if any, is noted below).

| receipt          | minted               | layers                             | status  |
|------------------|----------------------|------------------------------------|---------|

build (lake build (elaboration)) **current**

replay (leanchecker (official kernel replay)) **current**

hardened (safe\_verify (hardened screen)) current

decorrelated (lean4export + nanoda (decorrelated kernel)) current

comparator: none no fixture in the three-implementation comparator harness (compiled / kernel-interpreted / reference-interpreted) exercises this rule.

## HOL4 statement

### OUT OF SCOPE BY DESIGN

Out of scope for the HOL side *by design*, not by backlog: this rule is a *field* of the bridge rule (QSATFROMREGION's eval slot), never a node, so no wire certificate a HOL checker reads could ever contain a ROOTEval node; HOL coverage for this rule *is* the target rule's, and the box-atom branch is loader-side registry recomputation, likewise not a wire-format rule. Today even the target's statement is not writable: the HOL4 development (theory bern\_catalogue, the base catalogue's check-function cone) predates PCONSTEXACT, whose wire tag is unallocated — see that rule's section for the honest state of the target's own box.

## HOL verifier receipts

### NONE

no HOL verification receipt exists for this rule.

## Proof

Genre: alias rule (tier 3) — a respelling template: the  $1 \rightarrow 1$  unpack, the filled-in target application, the payload-transport table, the exactness identity, and the soundness corollary through the target's lemma. This row is the membership leaf itself, catalogued as a rule of its own because every initialized certificate ends with one; in the extension certificate schema it is a *field* of the bridge rule (QSATFROMREGION's eval slot), not a node sort. The judgment-level story lives in the bridge rule's section — this section owns the leaf. Mechanization state: the target's lemma is kernel-verified; the exactness identities are mechanized and bound in the entry, and so — now that the extension certificate schema exists — is the payload-level elaborator (the remark below names the bound functions).

**Recipe R67.1** (the template instance). One leaf  $\rightarrow$  one node: membership of the initial point  $x_0$  in the certificate's *root atom* — the region atom concluded at the root of the certificate (naming note: “root” refers to the certificate's root claim, not to roots of polynomials) — by exact rational evaluation. For a *sublevel* atom  $\{x : V(x) \leq y\}$  the unpack image is a single PCONSTEXACT application (Recipe R67.2). For a *box* atom the leaf is not a rule application at all: per-coordinate interval containment is recomputed directly by the checker's side-condition registry (conformance recomputation) — the alias reading covers the sublevel branch, and the box branch is stated so the respelling never overclaims. Nothing else is derived: the rule is a compact spelling of one ground-fact row.

**Recipe R67.2** (the filled-in application). Sublevel atom  $R = \{x : V(x) \leq y\}$  with  $V$  a polynomial over  $\mathbb{Q}$ , threshold  $y \in \mathbb{Q}$ , and initial point  $x_0$  with rational coordinates:

$$\frac{V(x_0) \leq y \text{ holds under exact evaluation in } \mathbb{Q}}{\Phi \vdash V(x_0) \leq y} \text{ PCONSTEXACT}$$

with arbitrary premise  $\Phi$ , as the target licenses (the rule is premise-free).  $V(x_0)$  denotes the closed term obtained by substituting every coordinate of  $x_0$  into  $V$  — closed by construction, so the target's verified evaluator decides the comparison in exact  $\mathbb{Q}$ , and a true verdict certifies closedness as a byproduct (the target section unpacks why).

### Recipe R67.3 (payload transport — field for field).

| ROOTEval data                | PCONSTEXACT payload                                        |
|------------------------------|------------------------------------------------------------|
| $x_0$ (rational coordinates) | substituted into the closed left-hand term                 |
| sublevel atom $(V, y)$       | the comparison's two sides                                 |
| comparator                   | $\leq$ (inside the admissible set)                         |
| box atom (per-axis bounds)   | <i>not</i> transported — registry recompute (Recipe R67.1) |

**Proposition R67.4** (the exactness identity).

$$x_0 \in \{x : V(x) \leq y\} \iff \text{evalClosed}(V(x_0) \leq y) = \text{true}.$$

*Proof.* Two lines, which is the point. Substituting a rational point into a rational polynomial is exact arithmetic — no rounding enters at any step — so the evaluator computes the value  $V(x_0)$  itself, not an approximation to it; and the decidable comparison of two exact rationals is the membership predicate verbatim. This is the degenerate — and best — case of the exactness identity an alias owes: not an algebraic rearrangement but a literal identity of values. It is also the whole rule: under naively rounded (non-directed) evaluation, a point lying  $\varepsilon$  outside the region could certify membership, and the bridge rule's instantiation (its section, the extension page) would conclude satisfaction from a false premise; directed outward rounding would keep that direction sound but surrender the equivalence — boundary points, where  $V(x_0) = y$  exactly, typically become undecidable (an outward enclosure that straddles the threshold cannot decide; an evaluation whose enclosure does not cross it — an exact zero-width value, or a one-sided enclosure touching the threshold — still decides).  $\square$

**Proposition R67.5** (soundness corollary). *If the leaf checks,  $x_0$  belongs to the root atom.*

*Proof.* `Formula.holds_of_evalClosed_true` (the target's kernel-verified evaluator theorem, quoted in the `PConstExact` section): a closed comparison whose exact evaluation returns true holds at every valuation. By Proposition R67.4 that is membership: substitution closed the formula, so  $V(x_0) \leq y$  mentions no wires, its truth is valuation-independent, and that truth is literally the sublevel atom's membership predicate at  $x_0$ . There is no other content — the alias genre working as intended. (For the box branch the recomputed per-coordinate containment plays the same role, warranted by the `recompute`'s definition rather than a rule lemma.)  $\square$

*Remark R67.6* (the payload-level elaborator, mechanized). The *semantic* content of the respelling is bound in the entry: `rootEval_eval_cast` is Proposition R67.4's literal identity of values, and `rootEval_sublevel_iff` / `rootEval_box_iff` are the two atom shapes as equivalences. The payload-level elaborator — previously this page's one absent artefact, held back until the extension certificate schema existed — is bound with it: `rootEvalElab` (module `BernsteinLogic.QtslElaborators`) takes  $(x_0, \text{atom})$  to exactly the one `PConstExact` payload of Recipe R67.3 (sublevel branch), as an inhabitant of the target's own payload type — the comparator confinement discharged at elaboration, once. The closed left-hand term is built by verified substitution (`polyClosedTerm`, whose evaluation lemma `polyClosedTerm_evalQ` says the checker's exact replay computes *the value  $V(x_0)$  itself*), `rootEvalFormula_true_iff` is Proposition R67.4's identity at the wire (the  $\mathbb{Q}$  face — both directions, as the proposition demands), and `rootEvalElab_sound` is the factoring through `sound_pConstExact`, itself one step to `Formula.holds_of_evalClosed_true`. The box branch is not elaborated, by design (Recipe R67.1: registry `recompute`, not a rule application).

*Remark R67.7* (the inherited comparator confinement). `PConstExact` excludes one comparator ( $\neq$ ) from its admissible set, for reasons of a second soundness invariant unpacked in that rule's section. The membership leaf uses  $\leq$  only — comfortably inside — but any port or mechanization of this rule must *preserve* the exclusion rather than re-derive the comparator set from the semantic lemma alone; the flag travels with the alias.

## Rule 68. BoxBERN (admissible rule)

### The rule (Steele metanotation)

as realized in the mechanized development; source row: QTSL-rules.toml — *BoxBern*. The metanotation statement is typeset by hand for notational quality; its mechanized ground truth is the Lean statement below, extracted from the sources at every build of this book and hash-bound. The rule *roster* is machine-checked (every mechanized rule tag round-trips to exactly one catalogue row); the statement *text* is editorial, checked by eye against the extracted Lean beside it.

$$\frac{\begin{array}{l} N \in \mathbb{Q}[z_1, \dots, z_n]; \quad D = \prod_v [a_v, b_v] \subseteq \mathbb{Q}^n \\ \varphi = (A, A^{-1}, b) : \quad A, A^{-1} : \mathbb{Q}^{[n] \times [n]}, \quad b : \mathbb{Q}^{[n]}; \quad \varphi(w) = A w + b \text{ (affine-rung witness; } \varphi \text{ omitted reads as id)} \\ \vdash A^{-1} A = 1_{[n]} \text{ (the one certified product, exact)} \\ \hat{N} = \varphi \circ N \text{ (exact substitution)} \quad \{b_\alpha \leq 0\}_\alpha \text{ (every tensor-product Bernstein coefficient of } \hat{N} \text{ over } D) \end{array}}{D \vdash \hat{N} \leq 0} \text{BoxBERN}$$

the witness is data with index structure — two square rational tensors and an offset vector, the declared inverse carried rather than computed, its sole obligation the exact product (over a field, one side suffices) — and the ladder above the affine rung is graded by each rung's own grader: an unimplemented rung is a named refusing variant, never a partial check. The pullback  $\hat{N} = \varphi \circ N$  is recomputed by the checker and never rides the certificate, so a laundered pullback is unrepresentable rather than detected. The enacted rule is stated from its landed realization (`check_box_row/check_wire_family` in the workshop checker, over the wire-family grammar; refusal witness  $(\alpha, b_\alpha)$ ) — its certificate content is out of scope of the current baked theory: a box-cell row family is the named successor, and this cell moves onto the theory row when a revision carries it.

BoxBERN is the tensor-product (box) sibling of BERNcone: where BERNcone certifies a polynomial predicate over a simplex-shaped region by exact Bernstein enclosure, BoxBERN certifies  $\hat{N} \leq 0$  over an axis-aligned rational box, with the polynomial optionally pulled back through a certified reparameterization witness first. A producer reaches for it wherever certificate cells are boxes rather than simplices — grid covers, dyadic bisection cells, per-cell contraction rows for discrete maps — because the obligation count is the product of per-axis degrees rather than the simplex count times a multinomial: at the worked fixture's shape (four variables, per-axis degrees (2, 4, 2, 4), total degree 8), one box costs 225 exact coefficients where the Kuhn-simplex decomposition of the same box costs  $24 \cdot 495 = 11,880$  — a structural gap that compounds with per-coefficient cost, measured at three orders of magnitude wall-clock on the acceptance fixture.

What the checker recomputes, given the row  $(N, \varphi, D)$ : that the reparameterization witness certifies (for an affine witness, shapes and the exact left-inverse identity  $A^{-1} A = 1$ ; later ladder rungs by their own graders; an unimplemented rung is a *named refusing variant*, never a partial check); the pullback  $\hat{N} = \varphi \circ N$  by exact substitution — no pullback ever rides the certificate, so a laundered  $\hat{N}$  is unrepresentable rather than detected; and then the enclosure itself: substitute  $x_v = a_v + (b_v - a_v) t_v$  per axis, change basis per axis at the polynomial's actual degrees, and test every tensor-product Bernstein coefficient against  $\leq 0$ , refusing with the first offending multi-index and its exact value. Everything is exact rational arithmetic; nothing consults a float.

Each hypothesis is load-bearing. Drop the slot certification and an uninvertible “witness” could smuggle a coordinate change under which the claim means something else entirely. Drop the recompute-the-pullback discipline and the checked polynomial decouples from the claimed one. Drop the per-coefficient sweep and the conclusion is unrelated to the box. The conclusion is deliberately narrow — one sign fact on one box — because the row *species* that consumes it (coverage of the operative region, S-procedure multipliers  $\lambda \geq 0$ , init/containment side rows) owns every regional and compositional obligation; this rule is the arithmetic leaf they all stand on.

**notes** The enclosure bound is conservative — coefficients overshoot the true range except at corners, where they interpolate — and completeness is recovered by subdivision exactly as for the simplex rule: SUBDIVIDE remains the completeness partner. Degrees enter the certified statement as *data*: any degree family admitting a valid tensor-Bernstein expansion encloses, so “use the actual degrees” is a checker cost policy, not a soundness premise. Degenerate axes ( $a_v = b_v$ ) are inside the statement — the substitution sends the axis to a constant and the enclosure is unaffected.

### Lean statement

BernsteinLogicAux.BoxBern .boxBern\_enclosure

statement bound

```
-- **The tensor-basis enclosure lemma** (soundness part (ii) of the
box-Bernstein rule): if the box-shifted claim polynomial
`N` on `(lo + (hi - lo)·u)` has tensor-Bernstein coefficients `b`, then any
bounds on `b` bound `N` on the box. `hexp` is the checker's exact-`Q`
replay obligation (the shift and basis-conversion passes); the conclusion
quantifies over the landed arena's box set. -/

statement bound

```
/-- **Per-axis affine substitution exactness** (doc (ii) proof-shape item
"per-axis affine substitution exactness — a diagonal T0 map"): evaluating
the shifted polynomial at `u` is evaluating the original at the shifted
point. -/
theorem aeval_boxShift (lo hi : Fin n → ℚ) (u : Fin n → ℝ)
  (N : MvPolynomial (Fin n) ℚ) :
  aeval u (boxShift lo hi N)
    = aeval (fun v => (lo v : ℝ) + ((hi v : ℝ) - (lo v : ℝ)) * u v) N
```

BernsteinLogicAux.BoxBern . **sum\_aeval\_tensorBern**

statement bound

```
/-- Sub-lemma 2c (partition of unity): the tensor basis sums to `1` on the
unit cube — "products of partitions of unity are partitions of unity"
(doc (ii)); univariate `bernsteinPolynomial.sum` distributed over the
product by `Fintype.prod_sum`. -/
theorem sum_aeval_tensorBern (d : Fin n → ℕ) (u : Fin n → ℝ) :
 $\sum \alpha : \forall v, \text{Fin } (d v + 1), \text{aeval } u (\text{tensorBern } d \alpha) = 1$ 
```

## Correspondence (Steele display $\leftrightarrow$ Lean)

**reviewer-certified against the displayed texts** The dictionary below is a reviewer-certified statement of how the mechanized statements above interpret the displayed rule: display metavariable  $\mapsto$  Lean binder, each display hypothesis  $\mapsto$  the premise or side condition carrying it, the display conclusion  $\mapsto$  the goal — with any deliberate difference in width between display and mechanization named outright. Certification is recorded as a hash triple over (the displayed cell, the extracted statement texts, this dictionary's own text); if any of the three changes, this block turns amber until a reviewer re-certifies. The correspondence claim itself remains editorial — reviewer-grade, not machine-checked; its machine-checked successor types each soundness statement against the rule as a structured object, and supersedes this block per rule as it lands.

The displayed rule — certified slot, exact pullback, coefficient sweep, conclusion  $\hat{N} \leq 0$  on  $D$  — maps onto the bound statements as follows.  $D \mapsto \text{lo hi} : \text{Fin } n \rightarrow \mathbb{Q}$  through `ratBox` (the same `GridCx.Box` object the transport theorems quantify over);  $\hat{N} \mapsto N : \text{MvPolynomial } (\text{Fin } n) \ \mathbb{Q}$  — the *pulled-back* polynomial, because the checker recomputes the pullback and hands the enclosure lemma its result: the slot legs (certification, replay) are consumed upstream by the transport theorems (`t0_soundness`, `t05_soundness_gridcx`, and the `T1/TC` rung lemmas), quoted and bound in their own sections, never re-stated here. One orientation divergence in the slot leg is named rather than left to the reader: the enacted checker verifies the *displayed* product — its single exact multiplication computes  $A^{-1}A$  and compares it with  $1_{[n]}$  (`affine_left_certified`) — whereas the Lean witness structure stores the *opposite* orientation (`AffineWitness.certified : A · A-1 = 1`) and derives the displayed one as the theorem `left_certified : A-1 · A = 1` (via `mul_eq_one_comm`; the matrices are square over the commutative ring  $\mathbb{Q}$ , so either product

determines the other and the two orientations are equivalent). The displayed coefficient table  $\mapsto$  the expansion hypothesis of `boxBern_enclosure`: an explicit representation of the `boxShift`-substituted polynomial as  $\sum_{\alpha} b_{\alpha} \prod_v B_{\alpha_v}^{d_v}$  — the u-space/x-space transport is a theorem (`aeval_boxShift`), not notation, and the degree family  $d$  is a binder, not a fixed choice. The displayed accept condition (every  $b_{\alpha} \leq 0$ )  $\mapsto$  the hypothesis of `boxBern_nonpos`, whose conclusion is verbatim one `hcells` premise of the transport theorems — the two compose without glue, which is the certified content of “exactly one premise of the landed transport theorems.” Width note, two-sided: `boxBern_enclosure_minmax` is strictly stronger than the accept condition needs (both range ends, where the rule consumes only the max side), and nothing certified is wider than the display — the slot legs live upstream by construction, and no coverage or multiplier obligation enters any binder here (the row species owns them, as the display says).

## Lean verifier receipts

module `BernsteinLogicAux.BoxBern`; bound build 110ba4bda664... (bound from receipt 6935ac926dca961f, 2026-08-03T20:13:44Z). A receipt records that named checking layers accepted a build: (module, compiled-artifact SHA-256, environment SHA-256, checker layers), minted when the checking gate ran; the store receipts attesting the bound build are listed with the layers each run credited. Nothing here asks the reader to trust the store: every layer is an independently runnable program over the quoted sources — rebuild the module and re-run the checkers to reproduce the verdict. Receipts attesting superseded builds credit no layer and are omitted from this rendering (the count of omissions, if any, is noted below).

| receipt          | minted               | layers             | status  |
|------------------|----------------------|--------------------|---------|
| 63a3e12578528f22 | 2026-08-02T02:06:52Z | build+decorrelated | current |
| c2fe5c957feb2507 | 2026-08-02T23:30:40Z | build+decorrelated | current |

| 6935ac926dca961f | 2026-08-03T20:13:44Z | build+decorrelated | current |
| a3e7c09b848c5808 | 2026-08-03T22:45:28Z | build+decorrelated | current |

8 further receipt(s) in the store attest superseded builds of this module and are omitted from this rendering.

### gate-layer coverage of the bound build:

build (lake build (elaboration)) current

replay (leanchecker (official kernel replay)) stale only

hardened (safe\_verify (hardened screen)) stale only

decorrelated (lean4export + nanoda (decorrelated kernel)) current

comparator: none no fixture in the three-implementation comparator harness (compiled / kernel-interpreted / reference-interpreted) exercises this rule.

## HOL4 statement

### NO HOL STATEMENT YET

The HOL family port (`checkFam_boxbern` + a `famEq` arm, the A1/A3 mechanism) is a named successor of the kernel leg that landed this rule — absence recorded at landing, with the mechanism that will discharge it, so this reason cannot silently go stale the way pre-wave absence reasons did.

## HOL verifier receipts

### NONE

no HOL verification receipt exists for this rule.

## Proof

Genre: admissible rule (tier 2) — admissible by *reduction to verified checking machinery*, the taxonomy's recorded boundary case. The reduction shape is stated first; the enclosure proposition it stands on is then proved in full, because it is the section's one piece of genuinely new mathematics — the tensor twin of the simplex grounding that `BERNCONE` already carries.

**Recipe R68.1** (the reduction — what the checker replays). A `BoxBERN` row is  $(N, \varphi?, D)$ : a claim polynomial  $N \in \mathbb{Q}[z_1, \dots, z_n]$ , an optional reparameterization witness  $\varphi$  from the ladder ( $\emptyset$  = identity), and an axis-aligned box  $D = \prod_v [a_v, b_v] \subseteq \mathbb{Q}^n$  in the witness's working coordinates. The discharge is three replays, all exact  $\mathbb{Q}$ , each standing on a named verified theorem rather than on catalogue structure:

1. *slot certification* — for an affine witness, shapes and the exact left-inverse identity  $A^{-1}A = 1$  (a left inverse suffices over a field); later ladder rungs certify by their own graders, and a rung without a grader is a *named refusing variant* — refused loudly, never half-checked.
2. *substitution replay* —  $\hat{N} = \varphi \circ N$  by exact substitution. No pullback field exists in the row, so a forged  $\hat{N}$  is unrepresentable rather than detected.

3. *enclosure* — the tensor-product Bernstein coefficients of  $\hat{N}$  over  $D$  (Proposition R68.2); accept iff every coefficient is  $\leq 0$ , refusing with the witness  $(\alpha, b_\alpha)$  otherwise.

The conclusion,  $\hat{N} \leq 0$  on  $D$ , is deliberately exactly one `hcells` premise of the landed transport theorems: coverage of the operative region, S-procedure multipliers, and `init/containment` side rows are owned by the consuming row species, never by this leaf.

**Proposition R68.2** (tensor-product Bernstein enclosure). *Let  $p \in \mathbb{Q}[x_1, \dots, x_n]$ , let  $D = \prod_v [a_v, b_v]$  with rational endpoints ( $a_v \leq b_v$ , degenerate axes allowed), and suppose that after the per-axis affine substitution  $x_v = a_v + (b_v - a_v)u_v$  the resulting polynomial admits the tensor-product Bernstein representation*

$$p(a + (b - a) \odot u) = \sum_{\alpha} b_{\alpha} \prod_{v=1}^n B_{\alpha_v}^{d_v}(u_v), \quad B_i^d(t) = \binom{d}{i} t^i (1-t)^{d-i},$$

for some degree family  $(d_v)$  and coefficients  $b_{\alpha} \in \mathbb{Q}$ ,  $\alpha \in \prod_v \{0, \dots, d_v\}$ . Then for every  $x \in D$ ,

$$\min_{\alpha} b_{\alpha} \leq p(x) \leq \max_{\alpha} b_{\alpha}.$$

In particular, if every  $b_{\alpha} \leq 0$  then  $p \leq 0$  on  $D$ .

*Proof.* Fix  $x \in D$ . Each coordinate lies in its interval, so there is a  $u \in [0, 1]^n$  with  $x_v = a_v + (b_v - a_v)u_v$  for every axis: on a non-degenerate axis take  $u_v = (x_v - a_v)/(b_v - a_v)$ ; on a degenerate axis ( $a_v = b_v$ ) the substitution is the constant  $a_v$  regardless of  $u_v$ , and  $u_v = 0$  serves. Substitution exactness — that evaluating  $p$  at this  $x$  equals evaluating the substituted polynomial at  $u$  — is a per-axis affine replay, not a notational identification (the bound statement keeps the two polynomials distinct and transports along the substitution lemma).

On  $[0, 1]$ , each Bernstein basis polynomial is nonnegative ( $t^i \geq 0$ ,  $(1-t)^{d-i} \geq 0$ , binomial coefficients positive) and each degree- $d$  family sums to 1:  $\sum_i B_i^d(t) = (t + (1-t))^d = 1$  by the binomial theorem. Products of partitions of unity are partitions of unity, so the tensor family  $\{\prod_v B_{\alpha_v}^{d_v}(u_v)\}_{\alpha}$  is a family of nonnegative weights summing to 1 at every  $u \in [0, 1]^n$ . Evaluating the representation at  $u$  therefore exhibits  $p(x)$  as a convex combination of the  $b_{\alpha}$ , and a convex combination lies between the minimum and the maximum of its generators. The accept condition is the corollary: if every generator is  $\leq 0$ , so is every convex combination.  $\square$

*Remark R68.3* (degrees are data; degenerate axes are inside the statement). Nothing in Proposition R68.2 privileges the polynomial's actual per-axis degrees: *any* degree family admitting a valid representation encloses, so the checker's "use the actual degrees after the shift" is a cost policy — smallest coefficient table — and never a soundness premise. Likewise a degenerate axis needs no exclusion: the substitution collapses it to a constant, degrees drop, and the convex-combination argument is untouched. Both points are formalization deltas made *explicit* in the bound statements, in the conservative direction — the expansion hypothesis speaks about the substituted polynomial (the u-space/x-space transport is a theorem), and the degree family is a binder.

*Remark R68.4* (conservatism, and where completeness comes from). The bound is not tight: coefficients overshoot the true range except at the corners of  $D$ , where the representation interpolates ( $B_i^d(0) = [i = 0]$ ,  $B_i^d(1) = [i = d]$ , so corner coefficients *equal* corner values). A true-but-refused row is repaired by subdivision — Bernstein enclosures converge under subdivision and degree elevation — so SUBDIVIDE is the completeness partner here exactly as for the simplex rule, and refusal is always the failure direction.

*Remark R68.5* (why a box rule at all — the obligation-count structure). At per-axis degrees  $(d_v)$ , one box costs  $\prod_v (d_v + 1)$  coefficients; the kernel-checkable simplex shape for the same box costs  $n!$  Kuhn simplices at  $\binom{d+n}{n}$  coefficients each (total degree  $d$ ). At the acceptance fixture's shape —  $n = 4$ , degrees  $(2, 4, 2, 4)$ ,  $d = 8$  — that is  $3 \cdot 5 \cdot 3 \cdot 5 = 225$  against  $24 \cdot \binom{12}{4} = 11,880$  per cell, and the per-coefficient work also drops (one-dimensional passes against multinomial walks). The measured same-harness gap on the fixture's 26 cells is three orders of magnitude wall-clock. None of this changes what is certified — the rule is an optimization of checker cost, not a widening of any claim.

## Rule 69. PEXPTYPEENCLOSURE (admissible rule)

### The rule (Steele metanotation)

as realized in the mechanized development; source row: QTSL-rules.toml — *PExpTypeEnclosure*. The metanotation statement is typeset by hand for notational quality; its mechanized ground truth is the Lean statement below, extracted from the sources at every build of this book and hash-bound. The rule *roster* is machine-checked (every mechanized rule tag round-trips to exactly one catalogue row); the statement *text* is editorial, checked by eye against the extracted Lean beside it.

$$\frac{f \in F \quad n \in \mathbb{N} \quad r, R \in \mathbb{Q} \quad a_k = a_k^f \text{ for } k = 0..n \text{ (exact coefficient recurrence)} \quad 0 \leq r < n + 2 \quad R \geq \frac{r^{n+1}}{(n+1)!} \cdot \frac{n+2}{n+2-r}}{\forall x, |x| \leq r \Rightarrow \left| f(x) - \sum_{k \leq n} a_k x^k \right| \leq R} \text{ PEXPTYPEENCLOSURE}$$

the coefficients are recomputed by the checker (never carried); the check is pure  $\mathbb{Q}$ -arithmetic and never evaluates  $f$ ; the real functions enter only in the kernel-checked soundness theorem. Scope of  $F$ : entire functions with exact- $\mathbb{Q}$  Maclaurin coefficients dominated by  $|a_k| \leq 1/k!$  (entire of exponential type, normalized) — exp, sin, cos, and (qtsl tower) the reduced error-function kernel; a new in-class function costs one coefficient recurrence + one domination case, the tail argument untouched. Finite-radius functions (log, rational powers) are certified by sibling routes, not by this rule; every downstream consumption decomposes into existing polynomial sequents (recentering, Taylor-model combination, endpoint substitution).

PEXPTYPEENCLOSURE is the calculus's one transcendental leaf: a remainder-bound rule that brackets a non-polynomial function between two polynomials with all data rational, so that every downstream obligation — recentering, Taylor-model combination, endpoint substitution into a generator inequality — decomposes into polynomial sequents the existing rules already check. A producer reaches for it wherever certified dynamics carry transcendental drift terms (pendulum-family sin / cos, rate and decay exp, Gaussian-kernel reductions): the rule certifies a Maclaurin truncation once, at a radius, with an explicit remainder, and from there the trusted arithmetic is exact rational computation exactly as for every other leaf.

The witness is  $(f, n, r, R)$ : a function tag  $f$  from the registered library, a truncation degree  $n$ , a radius  $r \in \mathbb{Q}_{\geq 0}$ , and a remainder budget  $R \in \mathbb{Q}$ . The check is pure rational arithmetic — the coefficients  $a_k^f$  are recomputed from  $(f, n)$  by exact per-tag recurrence rather than carried (a laundered coefficient list is unrepresentable on the wire), the radius must satisfy  $r < n + 2$ , and  $R$  must dominate the closed-form tail bound  $\frac{r^{n+1}}{(n+1)!} \cdot \frac{n+2}{n+2-r}$ . The checker never evaluates  $f$ ; the real functions enter only in the kernel-checked soundness theorem, which concludes the two-sided bracket  $|f(x) - \sum_{k \leq n} a_k x^k| \leq R$  on  $[-r, r]$ .

The scope is deliberately exact: *entire functions with exact-rational Maclaurin coefficients dominated by  $|a_k| \leq 1/k!$*  — entire of exponential type, normalized so  $e^{|x|}$  dominates coefficientwise. All three conditions are load-bearing: exact- $\mathbb{Q}$  recurrences make clause (i) checkable term-by-term; the  $1/k!$  domination is what lets ONE tail formula serve every tag; entirety means any rational radius works, subject only to the formula's own guard  $r < n + 2$ . This is strictly narrower than “anything with a closed-form Taylor series”: log and rational powers are analytic but not entire (a finite-radius variant would need a radius-ratio geometric tail and a domain side condition; they are certified today by sibling routes built on their own bounds), and tan is meromorphic (handled as sin / cos plus division at the consumer). Extending the library to a new in-class function costs one coefficient recurrence and one domination case — the tail argument is untouched. The error-function kernel exercised exactly this clause: under the  $y = z^2$  reduction its coefficients are  $(-1)^k / (k! (2k + 1))$ , dominated by  $1/k!$  verbatim, and the soundness statement needed no edits beyond the per-tag cases.

**notes** Admissible by reduction to verified checking machinery (the same boundary clause as BoxBERN): the checker replays encCheck, and the trust lands on the kernel-checked meaning theorems, never on catalogue structure. Conservativity: no new sequent theorems — the rule concludes into a sibling judgment kind, and its consumers re-enter the calculus as ordinary polynomial rows. Stated outright rather than smoothed: this is the one rule where transcendental meaning enters the trust story — a deliberate, priced, single-rule growth of the trusted base, carried by the soundness theorems cited below. Slack is the producer's business (pick  $n$ , recenter, subdivide): subdivision shrinks bracket width first-order while degree shrinks it factorially, and the measured budgets on the acceptance systems ran at degree 9 with remainders near  $10^{-7}$  — orders below the certificate margins they feed.

### Lean statement

BernsteinLogicAux.Enclosure . encCheck\_sound

statement bound

```
-- **The remainder-bound rule is sound** (note §1's boxed rule): a witness passing
`encCheck` certifies `|f(x) - P(x)| ≤ R` for every `|x| ≤ r`, where `f` is the tag's
real function and `P` the witness polynomial. -/
theorem encCheck_sound (w : EncWitness) (h : encCheck w = true) :
  ∀ x : ℝ, |x| ≤ (w.r : ℝ) →
    |w.tag.eval x - evalPoly w.coeffs x| ≤ (w.R : ℝ)
```

BernsteinLogicAux.Enclosure . **encCheck\_sound\_bracket**

statement bound

```

/-- Two-sided bracket form:  $P(x) - R \leq f(x) \leq P(x) + R$  on  $[-r, r]$  — the pair of
polynomial brackets the certificate's sequents consume (note §3). -/
theorem encCheck_sound_bracket (w : EncWitness) (h : encCheck w = true) :
   $\forall x : \mathbb{R}, |x| \leq (w.r : \mathbb{R}) \rightarrow$ 
    evalPoly w.coeffs x - (w.R :  $\mathbb{R}$ )  $\leq$  w.tag.eval x  $\wedge$ 
    w.tag.eval x  $\leq$  evalPoly w.coeffs x + (w.R :  $\mathbb{R}$ )

```

BernsteinLogicAux.Enclosure . **encCheck\_point**

statement bound

```

/-- Point-bracket corollary (producer recentering, note §3(1)): evaluating the witness at
a rational point `c` with  $|c| \leq r$  brackets the transcendental constant  $f(c)$ . -/
theorem encCheck_point (w : EncWitness) (h : encCheck w = true) (c :  $\mathbb{Q}$ )
  (hc :  $|c| \leq w.r$ ) :
    evalPoly w.coeffs (c :  $\mathbb{R}$ ) - (w.R :  $\mathbb{R}$ )  $\leq$  w.tag.eval (c :  $\mathbb{R}$ )  $\wedge$ 
    w.tag.eval (c :  $\mathbb{R}$ )  $\leq$  evalPoly w.coeffs (c :  $\mathbb{R}$ ) + (w.R :  $\mathbb{R}$ )

```

BernsteinLogicAux.Enclosure . **linear\_interp\_le**

statement bound

```

/-- Generator VCs are linear in each transcendental leaf occurrence: if  $A + C \cdot w \leq 0$ 
holds at both endpoints of  $[l, h]$ , it holds for every  $w \in [l, h]$ . With this, per-cell
interval hypotheses for the enclosed leaf discharge as TWO ordinary polynomial sequents —
no new wire dimension. -/
theorem linear_interp_le {A C l h w :  $\mathbb{R}$ } (hlw :  $l \leq w$ ) (hwh :  $w \leq h$ )
  (hl :  $A + C \cdot l \leq 0$ ) (hh :  $A + C \cdot h \leq 0$ ) :  $A + C \cdot w \leq 0$ 

```

QtslAux.Enclosure . **encCheck\_sound**

statement bound

```

theorem encCheck_sound (w : EncWitness) (h : encCheck w = true) :
   $\forall x : \mathbb{R}, |x| \leq (w.r : \mathbb{R}) \rightarrow$ 
     $|w.tag.eval x - evalPoly w.coeffs x| \leq (w.R : \mathbb{R})$ 

```

QtslAux.Enclosure . **encCheck\_sound\_bracket**

statement bound

```

theorem encCheck_sound_bracket (w : EncWitness) (h : encCheck w = true) :
   $\forall x : \mathbb{R}, |x| \leq (w.r : \mathbb{R}) \rightarrow$ 
    evalPoly w.coeffs x - (w.R :  $\mathbb{R}$ )  $\leq$  w.tag.eval x  $\wedge$ 
    w.tag.eval x  $\leq$  evalPoly w.coeffs x + (w.R :  $\mathbb{R}$ )

```

QtslAux.Enclosure . **integral\_exp\_neg\_sq**

statement bound

```

/-- The Gaussian integral reduces to the error-function kernel by the
substitution  $t = z * s$ :  $\int t \text{ in } (0:\mathbb{R})..z, \exp(-(t^2)) = z * T(z^2)$ .
Both sides are odd in  $z$ , and the oriented interval integral makes the
identity hold for every real  $z$  without a sign case split. Together with a
bracket for  $2 / \sqrt{\pi}$  (see two_div_sqrt_pi_mem) this carries polynomial
enclosures of  $T$  to enclosures of the error function. -/
theorem integral_exp_neg_sq (z :  $\mathbb{R}$ ) :
   $\int t \text{ in } (0:\mathbb{R})..z, \text{Real.exp } -(t^2) = z * \text{FnTag.erfT.eval } (z^2)$ 

```

Correspondence (Steele display  $\leftrightarrow$  Lean)

**reviewer-certified against the displayed texts** The dictionary below is a reviewer-certified statement of how the mechanized statements above interpret the displayed rule: display metavariable  $\mapsto$  Lean binder, each display hypothesis  $\mapsto$  the premise or side condition carrying it, the display conclusion  $\mapsto$  the goal — with any deliberate difference in width between display and mechanization named outright. Certification is recorded as a hash triple over (the displayed cell, the extracted statement texts, this dictionary's own text); if any of the three changes, this block turns amber until a reviewer re-certifies. The correspondence claim itself remains editorial — reviewer-grade, not machine-checked; its machine-checked successor types each soundness statement against the rule as a structured object, and supersedes this block per rule as it lands.

The displayed rule maps onto the bound statements as follows. The witness  $(f, n, r, R) \mapsto \text{EncWitness}$  (fields `func`, `deg`, `radius`, `rem`, plus the coefficient list governed by the displayed recurrence clause, recompute semantics per the flavor text); the three displayed check clauses  $\mapsto$  the definition of `encCheck`, whose acceptance is the single hypothesis of every soundness statement. The displayed conclusion  $\mapsto$  `encCheck_sound` (the absolute-value form) and `encCheck_sound_bracket` (the same content as a two-sided polynomial bracket — equal width, different packaging); `encCheck_point` instantiates the bracket at a rational point (the recentering step's constant legs), and `linear_interp_le` carries the endpoint-substitution step the consumers use. One deliberate width difference,

named outright: on the wire the coefficient vector is never serialized — the checker recomputes it — while the Lean witness carries the list explicitly and clause (i) checks it against the recurrence; the wire grain is therefore strictly narrower than the mechanized statement, and the coefficient-mutation receipts live kernel-side precisely because those mutations are unrepresentable on the wire. The two Lean packages prove the same statement shape over different tag libraries (the qtsl package adds the error-function kernel, with its meaning stated against the Gaussian integral and bridged by `integral_exp_neg_sq`); the HOL statements are the side-by-side port against transcTheory's natively per-index series — reindexing-free exactly where the Lean proof needed injection reindexing.

## Lean verifier receipts

module BernsteinLogicAux.Enclosure; bound build aeef11c4ffdf... (bound from receipt c61f02086268c593, 2026-07-21T00:02:40Z). A receipt records that named checking layers accepted a build: (module, compiled-artifact SHA-256, environment SHA-256, checker layers), minted when the checking gate ran; the store receipts attesting the bound build are listed with the layers each run credited. Nothing here asks the reader to trust the store: every layer is an independently runnable program over the quoted sources — rebuild the module and re-run the checkers to reproduce the verdict. Receipts attesting superseded builds credit no layer and are omitted from this rendering (the count of omissions, if any, is noted below).

### gate-layer coverage of the bound build:

- build (lake build (elaboration)) current
- replay (leanchecker (official kernel replay)) current
- hardened (safe\_verify (hardened screen)) current
- decorrelated (lean4export + nanoda (decorrelated kernel)) current

comparator: none no fixture in the three-implementation comparator harness (compiled / kernel-interpreted / reference-interpreted) exercises this rule.

## HOL4 statement

theory bern\_enclosure, HOL4 development script bern\_enclosureScript.sml script bound

### Definition encCheck\_def

```

Definition encCheck_def:
  encCheck w ⇔
    LENGTH w.coeffs = w.n + 1 ∧
    w.coeffs = GENLIST (maclaurin w.tag) (w.n + 1) ∧
    0 ≤ w.r ∧ w.r < &w.n + 2 ∧
    tailBound w.n w.r ≤ w.R
End

```

### Theorem encCheck\_sound

```
Theorem encCheck_sound:
  ∀w x.
    encCheck w ∧ abs x ≤ real_of_rat w.r ⇒
    abs (fnEval w.tag x - evalPolyR w.coeffs x) ≤ real_of_rat w.R
```

#### Theorem encCheck\_sound\_bracket

```
Theorem encCheck_sound_bracket:
  ∀w x.
    encCheck w ∧ abs x ≤ real_of_rat w.r ⇒
    evalPolyR w.coeffs x - real_of_rat w.R ≤ fnEval w.tag x ∧
    fnEval w.tag x ≤ evalPolyR w.coeffs x + real_of_rat w.R
```

## HOL verifier receipts

**documentary** Honest partial, stated as such: the port deliberately carries the MEANING theorem (`encCheck_sound` against `transcTheory's exp / sin / cos`), unlike the neighbouring slices whose meaning stays Lean-side. Of the theory's fifteen theorems, the eleven foundation theorems (datatypes through the factorial bound, including the full rational-to-real cast bridge) were machine-verified in a batch build; the four analysis theorems (`TERM_LE`, `MAJORANT_SUMS`, `TAIL_MAIN`, `encCheck_sound` with corollaries) are assembled from interactively-verified tactic pieces, and a full in-file batch re-verification currently exceeds the memory of every build host used to date (~117 GB resident observed at failure; a ≥256 GB host is the named path). Until that build lands, the HOL half is a stated port with interactive verification, not a batch-verified theory — the badge here says exactly that. The `encReceipts` table (seven rows, expected TTTFFFF) replays the same seven witnesses that appear byte-identically in the Lean kernel receipts and the reference checker's battery: three accepts (including one with  $R$  exactly at the tail bound) and four single-mutation rejects.

HOL receipts are documentary: quoted results of `hol-strict` runs and census rows from the HOL4 development's build evidence, not minted receipt artefacts. A HOL receipt store (the Lean store's twin) is named future work.

## Proof

Genre: admissible rule (tier 2) — admissible by *reduction to verified checking machinery*, the taxonomy's recorded boundary case. The reduction is stated first; the tail bound it stands on is then proved in full, because it is the section's one piece of genuinely new mathematics — and the one place in the whole calculus where the meaning of a transcendental function enters the trusted base.

**Recipe R69.1** (the reduction — what the checker replays). A `PExprTypeEnclosure` row is  $(f, n, r, R)$ : a function tag  $f$  from the registered library  $F$ , a truncation degree  $n \in \mathbb{N}$ , a radius  $r \in \mathbb{Q}_{\geq 0}$ , and a remainder budget  $R \in \mathbb{Q}$ . The discharge is three replays, all exact  $\mathbb{Q}$ :

1. *coefficient recompute* — the Maclaurin prefix  $a_0, \dots, a_n$  is regenerated from  $(f, n)$  by the tag's exact rational recurrence; no coefficient ever rides the certificate, so a laundered coefficient list is unrepresentable rather than detected.
2. *radius guard* —  $0 \leq r < n + 2$ , the side condition under which the closed-form tail bound below is finite and valid.
3. *remainder comparison* —  $R \geq \text{tail}(n, r)$  where  $\text{tail}(n, r) = \frac{r^{n+1}}{(n+1)!} \cdot \frac{n+2}{n+2-r}$ , a comparison of two explicit rationals.

Nothing here evaluates  $f$ . The conclusion — for all real  $x$  with  $|x| \leq r$ ,  $|f(x) - \sum_{k \leq n} a_k x^k| \leq R$ , i.e. the two-sided polynomial bracket  $P - R \leq f \leq P + R$  on  $[-r, r]$  — is the statement of the kernel-checked soundness theorem, and that theorem is where the real `exp`, `sin`, `cos` (as the proof assistant's own library defines them) enter, once, for the whole calculus.

**Proposition R69.2** (uniform Maclaurin tail bound). *Let  $f$  be entire with Maclaurin coefficients satisfying  $|a_k| \leq 1/k!$  for all  $k$  (rationality of the  $a_k$  is what makes the check exact; the bound itself needs only the domination). For  $n \in \mathbb{N}$  and  $0 \leq r < n + 2$ ,*

$$\sup_{|x| \leq r} \left| f(x) - \sum_{k \leq n} a_k x^k \right| \leq \frac{r^{n+1}}{(n+1)!} \cdot \frac{n+2}{n+2-r} = \text{tail}(n, r).$$

*Proof.* For  $|x| \leq r$  the omitted tail is dominated termwise:

$$\left| \sum_{k > n} a_k x^k \right| \leq \sum_{k > n} \frac{r^k}{k!}.$$

Write  $N = n + 1$  and index the tail by  $j \geq 0$  as  $k = N + j$ . The factorial lower bound  $(N + j)! \geq N! (N + 1)^j$  — induction on  $j$ : the base is trivial, and the step multiplies by  $N + j + 1 \geq N + 1$  — gives

$$\frac{r^{N+j}}{(N+j)!} \leq \frac{r^N}{N!} \left( \frac{r}{N+1} \right)^j.$$

The guard  $r < n + 2 = N + 1$  makes the ratio  $q = r/(N + 1)$  satisfy  $0 \leq q < 1$ , so the geometric series sums to  $1/(1 - q) = (N + 1)/(N + 1 - r)$ , and

$$\sum_{k > n} \frac{r^k}{k!} \leq \frac{r^N}{N!} \cdot \frac{N + 1}{N + 1 - r} = \frac{r^{n+1}}{(n+1)!} \cdot \frac{n+2}{n+2-r}.$$

□

Soundness of the rule is now the two-line composition the mechanized statements carry: clause (1) certifies that the recomputed prefix agrees with  $f$ 's true coefficients (a per-tag recurrence identity, proven once per library member against the library definition of  $f$ ); every registered tag satisfies the domination  $|a_k| \leq 1/k!$  (a per-tag lemma — for  $\exp$  an identity, for  $\sin / \cos$  the odd/even zero pattern, for the reduced error-function kernel  $|a_k| = 1/(k! (2k + 1))$ ); and Proposition R69.2 turns clauses (2)–(3) into the bracket. Accepting a witness with  $R$  *exactly* at  $\text{tail}(n, r)$  is sound — the receipt battery pins one such row on purpose — and every strengthening of the check (a smaller  $R$ , a larger  $r$ , a shortened prefix, a flipped coefficient sign) is refused by construction, which is what the four mutation receipts witness.

*Remark R69.3* (scope — what the class is, and is not). The hypotheses of Proposition R69.2 are the exact scope of the rule: entire, exact- $\mathbb{Q}$  coefficients, dominated by  $1/k!$  (entire of exponential type, normalized so  $e^{|x|}$  dominates coefficientwise). Each condition excludes something familiar. Finite-radius functions —  $\log$ , rational powers — fail entirety: a variant for them would carry a radius-ratio geometric tail *and* a domain side condition, and they are certified today by sibling routes built on their own bounds rather than by stretching this rule.  $\tan$  is meromorphic and out entirely; consumers build it from  $\sin / \cos$  and division. And  $e^{x^2}$  is entire but not of exponential type — its coefficients escape the domination, so no choice of  $n$  rescues the one uniform tail formula. Conversely, admitting a new in-class function costs exactly one coefficient recurrence and one domination case; the tail argument, the check, and the soundness statement shape are untouched — the error-function kernel entered this way, under a  $y = z^2$  reduction chosen precisely to land its coefficients inside the domination.

*Remark R69.4* (slack is the producer's business). The rule certifies one truncation at one radius; tightness is policy, not soundness. Recentering (the point brackets of the mechanized `encCheck_point`, combined by Taylor-model arithmetic over  $\mathbb{Q}$ ) and subdivision shrink bracket width first-order, while raising the degree shrinks it factorially — so producers buy accuracy with  $n$  and locality with cells, and every combination step re-enters the calculus as ordinary polynomial rows. On the measured acceptance systems, degree 9 at unit radius gave remainders near  $10^{-7}$ , orders below the certificate margins consuming them.

## 15.8 Morse Topology

### Rule 70. QMORSEDISCHARGE (core rule)

#### The rule (Steele metanotation)

as realized in the mechanized development; source row: QTSL-rules.toml — *QMorseDischarge*. The metanotation statement is typeset by hand for notational quality; its mechanized ground truth is the Lean statement below, extracted from the sources at every build of this book and hash-bound. The rule *roster* is machine-checked (every mechanized rule tag round-trips to exactly one catalogue row); the statement *text* is editorial, checked by eye against the extracted Lean beside it.

$$\begin{array}{l}
 L : \text{QBlockLattice (blocks over one rational grid)} \\
 \{F_f \vdash \sigma_f \mathcal{A}\ell_f > 0\}_{f \in \text{facets}(L)} \text{ (facet-sign rows: } \ell_f \text{ the facet's normal coordinate, } \sigma_f \in \{\pm 1\} \text{ the declared crossing sign, } F_f \text{ the facet)} \\
 h : \text{QCellMap (cell} \rightarrow \text{vertex} \sqcup \{\text{transit}\}) \quad \{\vdash T(b) \subseteq \rho(h(b))\}_{h(b) \neq \text{transit}} \text{ (containments, per vertex cell)} \\
 \{T(b) \vdash \mathcal{A}V_b + \varepsilon_b \leq 0\}_{h(b) = \text{transit}}, \quad \varepsilon_b \in \mathbb{Q}_{>0} \text{ (transits, per transit cell)} \\
 \{\vdash \rho(u) \cap \rho(v) = \emptyset\}_{u \neq v \in G}, \quad \{\vdash \rho(v) \subseteq D\}_{v \in G} \text{ (}\rho\text{-wf: rows where not box-aligned, recomputed where box-aligned)} \\
 \text{CR}(\mathcal{M}|_D) \subseteq \bigcup_{h(b) \neq \text{transit}} T(b) \text{ (cell-level chain-recurrence cover)} \\
 \text{MorseAssembly}(L, h, G, \rho) \text{ (the assembly ledger, defined below)} \\
 \hline
 \mathcal{M} \models \text{Morse}(D, G, \rho)
 \end{array}$$

the lattice payload carries name, grid, arena, and blocks, and enters as certificate data (a shared reference; the rows impose the claims); its per-facet sign rows are displayed inline as the second premise — each certifies a uniform strict sign of the flow across one grid facet ( $\mathcal{A}\ell_f$  is the vector field's facet-normal component on the facet, frozen at the gridline), and the transit certificates  $V_b$  ride the same payload. The  $\rho$ -wf obligations split by alignment: box-aligned disjointness/containment is bounded interval arithmetic, recomputed; non-box-aligned pairs are per-pair BL rows. The displayed *MorseAssembly* package comprises the assembly ledger — arena compactness, per-cell-pair crossing certificates on shared facets, orbit-interval order rows — plus profile identification and the ambient metric structure chain recurrence needs (model-class); the chain-recurrence cover is displayed as its own premise. Checker-recomputed: lattice/cell-map presentation conformance (closure recompute, join-irreducible readout, the acyclicity check on the spec graph, the arena inside the top member's realization — the nonemptiness row).

QMORSEDISCHARGE concludes the global Morse judgment: all recurrence of the model inside the arena lives in the declared regions  $\rho(v)$ , and transitions between them run only down the declared order. It is reduction-to-base in its cleanest form: the certificate is a lattice of blocks over one rational grid whose every internal facet carries a strictly-inward sign row of the base calculus, a map  $h$  sending the lattice's cells to spec vertices or to “transit”, containment rows placing each vertex cell inside its region, and per-transit-cell decrease rows  $\mathcal{A}V + \varepsilon \leq 0$  — every leaf a sequent the base kernel already checks, and zero new kernel rules.

A producer reaches for it from the refinement loop: synthesize the block family (splitting cells where a facet sign fails to certify, merging where refinement is not needed), pick transit observables from low-degree templates, and match cells to the spec graph. Failure mode is refusal with a pointer: a spec whose resolution exceeds what the certificate can contain reports exactly which cells obstruct, and that report is itself the useful artefact.

What the checker recomputes rather than trusts: the lattice closure under union and grid-level intersection; the readout — the join-irreducible members, their unique lower covers, the cells  $T(b) = \text{cl}(b \searrow b^-)$ , and the induced cell order; convexity of  $h$ 's fibres and monotonicity of  $h$  on vertex cells; acyclicity of the spec graph; and the box-aligned well-formedness checks on  $\rho$ . The witness the rule assembles is  $M(v) := \text{Inv}(\bigcup_{h(b)=v} T(b))$  — the invariant part of the fibre's cell-union, not the union of per-cell invariant parts; the proof section shows the distinction is load-bearing.

Each hypothesis earns its place. Drop the containment rows and the location clause fails. Drop the transit rows and a transit cell could harbour recurrence the  $\rho$ -cover misses. Drop fibre convexity and the judgment could assert a strict order the certificate does not enforce. Drop facet strictness and three arguments die at once: no-facet-riding, fibre disjointness, and the chain-margin bound (“strictness pays a second time”).

The mechanization is conditional, honestly: the bound theorems prove the witness assembly with a ledger of named hypothesis families — G3 (compactness of the invariant parts), discharged outright from model-class facts; G4 (disjointness of distinct fibres), reduced to transit certificates on fibre overlaps; G5 (the chain-recurrence cover), reduced to the cell-level cover; and G6 (the order clause), which remains a hypothesis of the statements bound here, its content being the block lattice's orbit combinatorics. The proof section renders each as mathematics, together with G2, the pointwise-to-integrated bridge that every certificate-shaped hypothesis consumes.

**notes** The judgment is deliberately an “at most” claim: empty Morse sets are permitted, so the rule certifies confinement of recurrence and of transition order, never existence of structure — the existence half (Conley indices, connection witnesses) is a separately priced annotation tier, absent by design. End-to-end certificate receipts exist in the development's exact-arithmetic certificate-checker lane, which accepts both direct and product-assembled Morse-family certificates against a mutant battery; those receipts ride the checker's own test suite, not this book's receipt store.

## Theory rows (geolog)

The rule's certificate content as it is declared in the geolog theory the checker loads — payload schema, side-condition demands, and axiom rows, quoted from the theory source at every build of this catalogue (a stale quotation cannot exist). Axiom modes: chase = the engine derives; report = a violation is a loud judgment; refuse = a violation gates admission. Side-condition relations are discharged by bounded evaluation at the engine's ground seam, never by derivation.

The rule's official certificate content in the geolog theory the checker loads. **QMorse** is the concluded judgment kind — the graph-over-regions claim, with its arena — and **QMorseDischarge** is this rule's payload entity, field for field the display's premise kit (lattice, cell map, containment/transit/well-formedness proof-leaf lists, and the per-transit-cell certificate polynomials in `transit_certs`). The arena tie is the quoted axiom: a discharged claim's arena is the lattice's, as a stated equation between hash-consed values. The R1 side condition is the demand relation `qtsl_morse_readout` — lattice closure and readout recompute, discharged by bounded evaluation at the engine's ground seam. And the transit rows'  $\Delta V$  is not an ambient operator: `qtsl_gen_form` is the derived generator-form seam tying the subject system and the certificate component  $V$  to the hypernet that says how  $V$  can change with duration — recomputed, never trusted as stored data.

## Lean statement

BernsteinLogic.QtslSoundness . **qMorseDischarge\_sound**

statement bound

```

/-- QMorseDischarge soundness – Lemma M(v), transcribed as the witness
assembly `M(v) := MaxInv(U_{h(b)=v} T(b))` (the note's own definition,
"the invariant part of the fiber's cell-union, NOT the union of per-cell
invariant parts" – its self-caught first-draft defect). PROVED outright:
the location clause (from the containment rows) and the invariance
clause (`maxInv_isInvariant`). INTERFACE (gaps G3–G6, each the named
prose paragraph of the note's M(v)/M(ii)/M(iii) proofs): compactness,
fiber disjointness, the chain-recurrence cover – into which the transit
rows enter via `transit_maxInv_empty` (M(iv), mechanized above) – and
the order clause. A successor leg mechanizing a gap discharges the
corresponding hypothesis; the statement is already the roster's. -/
theorem qMorseDischarge_sound (φ : Semiflow X) (D : Set X)
  (ρ : Vtx → Set X) (cells : ι → Set X) (hmap : ι → Option Vtx)
  (hContain : ∀ i v, hmap i = some v → cells i ⊆ ρ v)
  (hCompact : ∀ v, IsCompact (φ.MaxInv (fiberUnion cells hmap v)))

## Correspondence (Steele display ↔ Lean)

**a bound Lean statement CHANGED since certification — re-review and re-certify** The dictionary below is a reviewer-certified statement of how the mechanized statements above interpret the displayed rule: display metavariable  $\mapsto$  Lean binder, each display hypothesis  $\mapsto$  the premise or side condition carrying it, the display conclusion  $\mapsto$  the goal — with any deliberate difference in width between display and mechanization named outright. Certification is recorded as a hash triple over (the displayed cell, the extracted statement texts, this dictionary's own text); if any of the three changes, this block turns amber until a reviewer re-certifies. The correspondence claim itself remains editorial — reviewer-grade, not machine-checked; its machine-checked successor types each soundness statement against the rule as a structured object, and supersedes this block per rule as it lands.

The displayed judgment  $\mathcal{M} \models \text{Morse}(D, G, \rho) \mapsto$  the goal  $\text{MorseSat } \phi D \rho = \text{Nonempty } (\text{MorseWitness } \phi D \rho)$  — the Morse note §2.2 clauses (compactness, invariance, location, disjointness, chain-recurrence cover, order) packaged as a structure, so the certified conclusion is existential exactly as the judgment reads; the witness assembly  $M(v) := \text{MaxInv}(\bigcup_{h(b)=v} T(b))$  lives inside the proof

term of `qMorseDischarge_sound`, never in its statement. The display's spec graph  $G$  enters as the binder pair  $\text{Vtx} + [\text{PartialOrder } \text{Vtx}]$ : the semantics consumes only the reachability order (the `MorseWitness` docstring says so in words), and the dag check on the presentation's edge set is R1 recompute with no Lean counterpart — correctly. Order polarity carried exactly: `hOrder`'s conclusion places  $\alpha$ -limits in the strictly *higher* set and  $\omega$ -limits in the lower ( $w < v \wedge \alpha\text{Set } \gamma \subseteq \dots v \wedge \omega\text{Set } \gamma \subseteq \dots w$ ), the display's “transitions run only down the declared order.”

- the E2 lattice  $L$  and cell map  $h \mapsto$  the abstract binders `cells :  $\iota \rightarrow \text{Set } X$`  and `hmap :  $\iota \rightarrow \text{Option } \text{Vtx}$`  (`none = transit`, the display's  $\sqcup \{\text{transit}\}$ ): the whole lattice stratum — closure recompute, join-irreducible readout,  $T(b)$ , fibre convexity and monotonicity of  $h$ , box-aligned  $\rho$ -wf — is presentation the checker recomputes (side condition R1), and the bound statements never see it; they quantify over arbitrary cell families, strictly wider than the display, in the safe direction.
- containment rows  $\mapsto$  `hContain (hmap i = some v  $\rightarrow$  cells i  $\subseteq$   $\rho$  v)`, one-to-one at the semantic stratum.
- transit rows  $\mathcal{AV} + \varepsilon \leq 0 \mapsto$  `hTransitCert i` (per `hmap i = none`) in the semantic-shadow form `HasTransitCert`: some observable  $V$ , bounded below on the cell, with explicit margin  $\varepsilon > 0$  and the *integrated* decrease clause  $V(\Phi_t x) \leq V(x) - \varepsilon t$  along confined prefixes. The pointwise-to-integrated bridge (gap G2; the `FlowDerivOn` profile identification) is outside this bound set — the roster witness cites its mechanization (`QtslMeanValue.lean`), not bound here.
- $\rho$ -wf rows  $\mapsto$  nothing: no bound hypothesis consumes them (fibre disjointness arrives through `hOverlap` instead) — R1 territory, like the lattice.
- the conditional ledger, exactly as bound: `qMorseDischarge_sound` carries G3–G6 as hypotheses (`hCompact/hDisj/hCR/hOrder`); `_modelClass` discharges G3 outright (`maxInv_isCompact`: Tychonoff, consuming `[T2Space X]`, spacewise flow continuity `hflow`, `[Finite  $\iota$ ]` + compact cells via `fiberUnion_isCompact` — model-class facts all), reduces G4 to overlap transit certificates (`HasTransitCert.disjoint_maxInv`: forward confinement on both sides, no backward uniqueness), reduces G5 to the cell-level cover `hCell (M(iii), KMV-III, literature strength)` through `crCover_assemble + HasTransitCert.maxInv_empty (M(iv))`, and carries G6 (`hOrder`) untouched.

Width note, both directions stated. Three assembly statements extend the bound set (the three assembly blocks below): the order assembly (`qMorseDischarge_sound_orderAssembled`, module `QtslOrderAssembly`) derives `hOrder` — G6 proper — carrying instead arena compactness, the two R1 shadows, and G6a, the orbit-interval row; the eventual-member assembly (`qMorseDischarge_sound_eventualMember`, module `QtslEventualMember`) derives G6a in turn from the block-family interface (the five R1-recompute combinatorial rows, per-member forward invariance, closedness, strict-inwardness shadows), leaving nothing of G6 under its own name; and the crossing assembly (`qMorseDischarge_sound_cellCover`, module `QtslCrossing`) sharpens G4 to the row shape — per-cell-pair crossing certificates on shared facets in place of whole-fibre-overlap transit certificates. All three are hash-bound, so the certified reach extends past `_modelClass`'s ledger and the conditional residue shrinks to the ledger's G1b/G2-class profile identifications (the `FlowDerivOn V (AV)` chain-rule bridges — the mean-value and Dini profile strata remain cited theorems, not bound), the cell-level chain-recurrence cover — now a displayed premise ( $\text{CR}(\mathcal{M}|_D) \subseteq \bigcup T(b)$  over vertex cells) —  $\mapsto$  `hCell` (the fibre-to-cell margin argument is the proof's stated residue), and the displayed `MorseAssembly` package  $\mapsto$  the remaining crossing/order/interface hypotheses plus recompute conformance. Binder cargo: `[PseudoMetricSpace X]` is consumed by chain recurrence itself —  $(\varepsilon, T)$ -chains need distances — ambient structure the assembly package carries.

## Lean verifier receipts

module `BernsteinLogic.QtslSoundness`; bound build 77005991d61d... (bound from receipt 8130a7a7a679cef4, 2026-08-04T01:16:06Z). A receipt records that named checking layers accepted a build: (module, compiled-artifact SHA-256, environment SHA-256, checker layers), minted when the checking gate ran; the store receipts attesting the bound build are listed with the layers each run credited. Nothing here asks the reader to trust the store: every layer is an independently runnable program over the quoted sources — rebuild the module and re-run the checkers to reproduce the verdict. Receipts attesting superseded builds credit no layer and are omitted from this rendering (the count of omissions, if any, is noted below).

| receipt          | minted               | layers             | status  |
|------------------|----------------------|--------------------|---------|
| 8130a7a7a679cef4 | 2026-08-04T01:16:06Z | build+decorrelated | current |
| 9eb3706354082144 | 2026-08-04T02:23:12Z | build+decorrelated | current |

5 further receipt(s) in the store attest superseded builds of this module and are omitted from this rendering.

module `BernsteinLogic.QtslDischarge`; bound build 4aa46910a600... (bound from receipt dd2946805f790f99, 2026-08-04T01:16:09Z). A receipt records that named checking layers accepted a build: (module, compiled-artifact SHA-256, environment SHA-256, checker layers), minted when the checking gate ran; the store receipts attesting the bound build are listed with the layers each run credited. Nothing here asks the reader to trust the store: every layer is an independently runnable program over the quoted sources — rebuild the module and re-run the checkers to reproduce the verdict. Receipts attesting superseded builds credit no layer and are omitted from this rendering (the count of omissions, if any, is noted below).

#### gate-layer coverage of the bound build:

build (lake build (elaboration)) current

replay (leanchecker (official kernel replay)) current

hardened (safe\_verify (hardened screen)) current

decorrelated (lean4export + nanoda (decorrelated kernel)) current

**comparator:** none no fixture in the three-implementation comparator harness (compiled / kernel-interpreted / reference-interpreted) exercises this rule.

## HOL4 statement

### NO HOL STATEMENT YET

Absent, and honestly so at two levels. The HOL4 development's object is the base-kernel checker cone — the first-order computational surface of the sequent-stratum certificate contract (dtype factorization, exact rational arithmetic, the catalogue check functions) — and the satisfaction-judgment stratum this rule concludes in has no HOL twin: no Morse-family or judgment-stratum definition exists in the ported scripts (verified against the port's definition inventory). The base leaves this rule consumes — facet-sign, containment, and decrease rows — ARE covered by the ported checker; what has no HOL counterpart is the judgment-stratum soundness development itself, which today is Lean-only. A port would be new assurance surface over the semiflow stratum, not a translation of existing checker code.

## HOL verifier receipts

**NONE**

no HOL verification receipt exists for this rule.

**Proof**

Genre: core rule (tier 1) — an ordinary mathematical proof at Putnam-exam-solution detail; the largest mechanized lemma set in this book. The rule’s mechanization is *conditional*: the soundness theorem is proved with a ledger of four named hypothesis families, of which one is discharged outright below, two are reduced to transit-certificate form, and the fourth — the order clause — is carried as an explicit hypothesis by the discharged-floor theorem and discharged by the separately bound assembly legs (ledger remark). The ledger remark near the end states each as mathematics. Every hypothesis is used and remarked on; the formal-anchor table maps each step to the Lean declaration that carries it.

**Setting.** Fix a forward semiflow  $\varphi$  on a metric state space  $X$  ( $\Phi_0 = \text{id}$ ,  $\Phi_{s+t} = \Phi_t \circ \Phi_s$ ), and a compact forward-invariant arena  $D \subseteq X$ . Four standard notions, exactly as the mechanized statements carry them:

(complete orbits)  $\gamma : \mathbb{R} \rightarrow X$  is a complete orbit when  $\gamma(s+t) = \Phi_t(\gamma(s))$  for all  $s \in \mathbb{R}$ ,  $t \geq 0$  — a two-sided trajectory compatible with the forward flow.

(maximal invariant part) for  $C \subseteq X$ ,

$$\text{Inv}(C) := \{x : \exists \gamma \text{ complete orbit, } \gamma(0) = x, \text{ range } \gamma \subseteq C\}.$$

An *invariant set*  $S$  (the sense fit for a semiflow) is one that is forward-invariant and satisfies  $S \subseteq \text{Inv}(S)$  — every point rides a complete orbit inside.

(limit sets)  $\omega(\gamma) := \bigcap_T \text{cl } \gamma([T, \infty))$  and  $\alpha(\gamma) := \bigcap_T \text{cl } \gamma((-\infty, T])$ .

(chains) an  $(\varepsilon, T)$ -chain from  $x$  to  $y$  inside  $D$  is a finite concatenation of orbit segments of duration  $\geq T$  with jumps of size  $< \varepsilon$  at points of  $D$  (generated by: a single step  $x, y \in D$ ,  $t \geq T$ ,  $\text{dist}(\Phi_t x, y) < \varepsilon$ ; and transitivity). A point is *chain-recurrent* in  $D$  when for every  $\varepsilon > 0$  and  $T$  there is an  $(\varepsilon, T)$ -chain from  $x$  to itself.

**The judgment.**  $\mathcal{M} \models \text{Morse}(D, G, \rho)$  holds when some family  $\{M(v)\}_{v \in V(G)}$  — indexed by the poset the graph  $G$  presents by reachability — satisfies: each  $M(v)$  compact and invariant; the family pairwise disjoint; (location)  $M(v) \subseteq \rho(v)$ ; (completeness of the cover) every chain-recurrent point of  $\varphi|_D$  lies in some  $M(v)$ ; and (order) every complete orbit in  $D$  contained in no single  $M(v)$  has  $\alpha(\gamma) \subseteq M(v)$  and  $\omega(\gamma) \subseteq M(w)$  for some  $w < v$ . The order runs source-to-sink:  $w < v$  means connecting orbits may run from  $M(v)$  down to  $M(w)$ , so the  $\alpha$ -side vertex is the higher one. Empty  $M(v)$  are permitted — the judgment is an “at most this structure” claim (recurrence confined to the  $\rho(v)$ , transitions confined to the order), never an existence claim; the existence half is a separately priced annotation tier (Conley indices, connection matrices), deliberately absent here.

**The rule’s data and the checker’s recompute.** The certificate supplies: the family object — a finite lattice of box-union blocks over one declared rational grid, each internal facet carrying a strictly-inward sign row (the `QBLOCKINV` section’s row species; the same rows serve both rules); a cell map  $h$  from the lattice’s cells to  $V(G) \sqcup \{\text{transit}\}$ ; per vertex cell a containment row  $T(b) \subseteq \rho(h(b))$ ; per transit cell a polynomial  $V$  with decrease rows  $\mathcal{A}V + \varepsilon \leq 0$ ; and well-formedness rows for  $\rho$ . The checker *recomputes*, rather than trusts, the lattice readout: closure under union and grid-level intersection, the join-irreducible members  $b$  with unique lower covers  $b^-$ , the cells  $T(b) := \text{cl}(b \setminus b^-)$ , the induced cell order, convexity of  $h$ ’s fibres and monotonicity of  $h$  on vertex cells, and acyclicity of  $G$ . Writing  $\text{fib}(v) := \bigcup_{h(b)=v} T(b)$  for the fibre’s cell-union, the witness the rule assembles is

$$M(v) := \text{Inv}(\text{fib}(v))$$

— the invariant part of the fibre’s cell-union, not the union of per-cell invariant parts. The distinction is load-bearing (Remark R70.11).

**Lemma R70.1** (Inv is located and invariant). (i)  $\text{Inv}(C) \subseteq C$ . (ii)  $\text{Inv}(C)$  is an invariant set.

*Proof.* (i) The witnessing orbit passes through  $x$  at time 0 with range in  $C$ . (ii) Two facts, both by time-shifting: shifting a complete orbit by any  $s$  ( $u \mapsto \gamma(u+s)$ ) is again a complete orbit, and every point  $\gamma(s)$  of an orbit with range in  $C$  therefore lies in  $\text{Inv}(C)$  with the shifted orbit as witness. Forward invariance: for  $x \in \text{Inv}(C)$  with orbit  $\gamma$ ,  $\Phi_t x = \gamma(0+t)$  is such a point. The complete-orbit-through clause: the same statement at every shift shows  $\text{range } \gamma \subseteq \text{Inv}(C)$ , so the witnessing orbit itself runs inside  $\text{Inv}(C)$ .  $\square$

**Lemma R70.2** (location). Under the containment rows,  $\text{fib}(v) \subseteq \rho(v)$ , hence  $M(v) \subseteq \rho(v)$  by Lemma R70.1(i).

*Proof.* A union of cells each inside  $\rho(v)$  is inside  $\rho(v)$ .  $\square$

**Lemma R70.3** (forward confinement). If  $x \in \text{Inv}(C)$  then  $\Phi_t x \in C$  for every  $t \geq 0$ .

*Proof.* The witnessing orbit’s forward half is the forward orbit:  $\Phi_t x = \Phi_t(\gamma(0)) = \gamma(t) \in C$ . This one-line lemma is the section’s quiet workhorse: a semiflow is deterministic *forward*, so membership in an Inv set constrains the actual forward trajectory — and nothing here assumes backward uniqueness (a semiflow may branch backward; complete orbits through a point need not be unique). The disjointness reduction below survives precisely because it only ever uses forward halves.  $\square$

**Lemma R70.4** (transit certificates kill invariance). Call  $C$  transit-certified when there are  $V : X \rightarrow \mathbb{R}$  and  $\varepsilon > 0$  with  $V$  bounded below on  $C$  and, along every forward trajectory confined to  $C$ ,  $V(\Phi_t x) \leq V(x) - \varepsilon t$ . Then no point is forward-confined to  $C$ ; in particular  $\text{Inv}(C) = \emptyset$ .

*Proof.* Suppose  $\Phi_t x \in C$  for all  $t$ , and let  $m$  bound  $V$  below on  $C$ . By the Archimedean property choose  $n$  with  $n\varepsilon > V(x) - m$ ; the decrease clause at horizon  $n$  gives  $V(\Phi_n x) \leq V(x) - \varepsilon n < m$ , contradicting  $\Phi_n x \in C$ . The Inv statement follows by Lemma R70.3. (The certified rows are pointwise  $-\mathcal{A}V + \varepsilon \leq 0$  on the cell, for the deterministic generator  $\mathcal{A} = f \cdot \nabla$  — and reach the integrated clause used here by integrating the derivative along the trajectory; that bridge is ledger item G2 in Remark R70.10, stated once and consumed by every certificate-shaped hypothesis in this section.)  $\square$

**Lemma R70.5** (disjointness from overlap certificates). *If  $C_1 \cap C_2$  is transit-certified, then  $\text{Inv}(C_1)$  and  $\text{Inv}(C_2)$  are disjoint.*

*Proof.* A common point is forward-confined to  $C_1$  and to  $C_2$  (Lemma R70.3 twice), hence to  $C_1 \cap C_2$  — which Lemma R70.4 forbids. No backward uniqueness, no injectivity of the flow maps.  $\square$

*Remark R70.6* (why the certificate sits on the overlap — “strictness pays a second time”). Distinct fibres’ cell-unions intersect only in shared boundary faces (cell interiors are disjoint by the readout’s construction — generically facets, but possibly lower-dimensional: two cells may meet in an edge or a corner alone). On a certified facet incident to a shared face, the facet polynomial supplies the observable — oriented to decrease: the rows certify inward growth of  $\ell$ , so the transit observable Lemma R70.4 consumes is  $V = -\ell$ , bounded below on the compact overlap, with the certified strict rate as its  $\varepsilon$ ; the shared face lies in  $\ell$ ’s zero set, and confinement to the face would force  $\ell \equiv 0$ . Where the overlap is a union of several faces, one signed observable per face does not by itself assemble into a single global certificate — the row-shaped assembly is per-cell-pair crossing certificates on shared facets, the development’s G4 sharpening, bound in this edition (anchor table) — and the hypothesis Theorem R70.9 takes is the assembled overlap certificate. The strict margin of the QBLOCKINV rows is thus consumed a second time, as the transit raw material for facet regions. One might hope to weaken the hypothesis to per-piece certificates — each  $C_i$  separately transit-certified — and conclude something about the union; that is false. On the circle rotation, two overlapping closed arcs each carry a monotone angular observable (a transit certificate for the arc), yet the union is the whole circle, every point recurrent: certificates on pieces do not compose across an overlapping union, because no global observable exists. The overlap form is the correct, and certifiable, hypothesis.

**Lemma R70.7** (compactness of the invariant parts). *Suppose  $X$  is Hausdorff, each flow map  $\Phi_t : X \rightarrow X$  is continuous, and  $C$  is compact. Then  $\text{Inv}(C)$  is compact. Consequently each  $\text{fib}(v)$ , a finite union of compact cells, has compact invariant part.*

*Proof.* Let  $K \subseteq X^{\mathbb{R}}$  (product topology) be the set of complete orbits with range in  $C$ :

$$K = \left( \bigcap_{s \in \mathbb{R}, t \geq 0} \{ \gamma : \gamma(s+t) = \Phi_t(\gamma(s)) \} \right) \cap \prod_{r \in \mathbb{R}} C.$$

Each orbit constraint is the equalizer of two continuous maps — evaluation at  $s+t$ , and  $\Phi_t \circ$  (evaluation at  $s$ ) — hence closed,  $X$  being Hausdorff; the product  $\prod_{\mathbb{R}} C$  is compact by Tychonoff (the one genuinely infinitary step of this section); a closed subset of a compact set is compact. And  $\text{Inv}(C)$  is exactly the image of  $K$  under evaluation at 0, a continuous map, hence compact. The fibre statement: a finite union of compact cells is compact, and the above applies to it.  $\square$

**Lemma R70.8** (the cover assembles from the cell level). *Suppose (cell-level cover) every chain-recurrent point of  $\varphi|_D$  lies in  $\text{Inv}(T(b))$  for some cell  $b$ , and (transit rows) every transit cell is transit-certified. Then every chain-recurrent point of  $\varphi|_D$  lies in some  $M(v) = \text{Inv}(\text{fib}(v))$ .*

*Proof.* Let  $x$  be chain-recurrent,  $x \in \text{Inv}(T(b))$ . If  $h(b) = \text{transit}$ , Lemma R70.4 makes  $\text{Inv}(T(b))$  empty — contradiction; so  $h(b)$  is a vertex  $v$ . Then  $T(b) \subseteq \text{fib}(v)$ , and  $\text{Inv}$  is monotone in its region (a complete orbit inside the cell is inside the fibre’s union), so  $x \in \text{Inv}(\text{fib}(v))$ .  $\square$

**Theorem R70.9** (soundness of QMORSEDISCHARGE, at the discharged floor). *Suppose: (model class)  $X$  is a Hausdorff metric space, each flow map  $\Phi_t$  is continuous, and every cell is compact; (containment rows)  $T(b) \subseteq \rho(h(b))$  for every vertex cell; (overlap certificates) for  $v \neq w$ , the overlap  $\text{fib}(v) \cap \text{fib}(w)$  is transit-certified; (cell-level cover) every chain-recurrent point of  $\varphi|_D$  lies in some cell’s invariant part; (transit rows) every transit cell is transit-certified; and (order clause) every complete orbit in  $D$  contained in no single  $M(v)$  connects a strictly higher fibre’s invariant part to a strictly lower one, in the sense of the judgment’s order clause with  $M(v) = \text{Inv}(\text{fib}(v))$ . Then  $\mathcal{M} \models \text{Morse}(D, G, \rho)$ .*

*Proof.* Take the family  $M(v) := \text{Inv}(\text{fib}(v))$  and check the witness clauses. *Location:* Lemma R70.2. *Invariance:* Lemma R70.1(ii). *Compactness:* Lemma R70.7 under the model-class facts. *Disjointness:* Lemma R70.5 applied to the overlap certificates. *Cover:* Lemma R70.8 from the cell-level cover and the transit rows. *Order:* the hypothesis, verbatim. All six clauses hold, so the family witnesses the judgment.  $\square$

*Remark R70.10* (the gap ledger, as mathematics). The rule was first mechanized as the bare witness assembly: location and invariance proved outright, and four clauses — labelled G3–G6 in the development, the labels this book adopts as the rule’s hypothesis names — taken as opaque interface hypotheses. The discharge stratum bound by this section moves the ledger to the state Theorem R70.9 exhibits:

G3 (compactness of the invariant parts): *proven*. Lemma R70.7 derives it from model-class facts alone — Hausdorff state space, spacewise-continuous flow, compact cells. No compactness hypothesis survives at the fibre level.

G4 (disjointness of distinct fibres’ invariant parts): *reduced, and sharpened to rows*. Lemma R70.5 trades it for transit certificates on pairwise overlaps; the residue is the overlap observable of Remark R70.6 — shared-facet functionals whose certified strict signs are the raw material — together with the G2 bridge below; and the row-shaped assembly (per-cell-pair crossing certificates on shared facets in place of whole-overlap certificates) is mechanized and bound (qMorseDischarge\_sound\_cellCover, anchor table).

G5 (completeness of the chain-recurrence cover): *reduced*. Lemma R70.8 trades the fibre-level cover for the cell-level one. The residue is the margin argument: a chain-recurrent point’s chains stay within its own cell, because the strict facet margin is a uniform

bound on admissible chain jumps near facets — an  $\varepsilon$ -chain with  $\varepsilon$  below the margin can no more exit a block than an orbit can. The classical home of this containment is Conley’s theory [47]; its algorithmic form is the chain-recurrence algorithm of Kalies–Mischaikow–van der Vorst [130].

*G6 (the order clause): a hypothesis of Theorem R70.9, discharged by the bound assembly legs.* Its mathematical content is the orbit combinatorics of the block lattice: the *eventual member* of a forward orbit — the minimal lattice member containing a forward tail, well-defined because the tail-containing family is finite, closed under the lattice meet, and nonempty: the arena sits inside the top member’s realization (one of the combinatorial interface rows the assembly legs consume), so the top member contains every forward tail — descends the cell order and stabilizes, giving every complete orbit in  $D$  extreme cells  $b_\omega \leq b_\alpha$  that bracket every visited cell; the fibre-convexity case analysis then converts bracketing into the witness’s order clause (the extremes are not transit, by Lemma R70.4 against their nonempty invariant limit sets; a same-fibre pair traps the whole orbit in its fibre by convexity, contradicting the “no single  $M(v)$ ” hypothesis; distinct fibres yield the strict order by monotonicity of  $h$ ). The development’s assembly legs mechanize exactly this — the cell order entering as theorem-interface data, the eventual-member construction proved against combinatorial row hypotheses — and are bound in this edition (qMorseDischarge\_sound\_orderAssembled, \_eventualMember; anchor table), so nothing of G6 survives under its own name: the residue is the R1-recompute combinatorial rows and strict-inwardness shadows those legs consume, plus the G2-class profile identifications below. Theorem R70.9 is stated at the discharged floor and takes the clause as an explicit hypothesis there; the rule’s conditional badge is judged against the full bound set.

*G2 (the pointwise-to-integrated bridge), named for completeness:* every “transit-certified” hypothesis above is the integrated semantic shadow of pointwise rows  $AV + \varepsilon \leq 0$ ; the bridge is one-variable calculus along trajectories, and its surviving analytic content is the identification of the certified polynomial rate with the trajectory-wise derivative on the region — the same model-class profile warrant as ledger item (a) of the QBLOCKINV section, whose G1 (block invariance) completes the shared ledger.

*Remark R70.11 (the witness is Inv of the union, not the union of Invs).* Define instead  $M'(v) := \bigcup_{h(b)=v} \text{Inv}(T(b))$  and the order clause fails: a complete orbit crossing between two cells of the *same* fibre lies in no per-cell invariant part (its range is in neither cell alone), so it belongs to no  $M'(v)$  while also connecting nothing strictly ordered — the “orbit contained in no Morse set” case triggers with no higher/lower pair to name. The correct definition absorbs such orbits into their fibre’s  $M(v)$ , which is exactly the role of fibre convexity: every cell between the orbit’s extremes maps to the same vertex, so the whole orbit lies in the fibre’s union and hence in its invariant part. Without convexity the judgment could assert a strict order the certificate does not enforce — convexity of  $h$ ’s fibres is well-formedness, not a nicety, and the checker recomputes it.

*Remark R70.12 (relation to the literature).* The judgment is Conley’s Morse decomposition [47] in certified form: a decomposition indexed by a two-element order is an attractor–repeller pair, and the general form is the lattice-refined iteration of that idea; the completeness clause is the containment of chain recurrence in the Morse sets, and the certified staircase of lattice members is a finite shard of a complete Lyapunov function (Conley’s fundamental theorem). The block-lattice route — attracting blocks closed under union and intersection, join-irreducibles, the tessellation into cells  $T(b)$ , and Birkhoff duality [22] between the attractor lattice and the Morse-graph poset — is the program of Kalies–Mischaikow–van der Vorst’s lattice series [131, 132]; the chain-recurrence cover’s algorithmic form is their earlier chain-recurrence algorithm [130]; and the computational tradition of certifying global dynamics by index machinery is surveyed in Mischaikow–Mrozek [183]. What the rule adds to that tradition is the artefact discipline: those pipelines end in trusted computation, while here every analytic claim rides certified sign rows — base kernel sequents in exact  $\mathbb{Q}$  — plus combinatorics the checker recomputes, with the semantic warrant being the lemma chain above.

## Rule 71. QMORSEPRODUCT (core rule)

### The rule (Steele metanotation)

as realized in the mechanized development; source row: QTSL-rules.toml — *QMorseProduct*. The metanotation statement is typeset by hand for notational quality; its mechanized ground truth is the Lean statement below, extracted from the sources at every build of this book and hash-bound. The rule *roster* is machine-checked (every mechanized rule tag round-trips to exactly one catalogue row); the statement *text* is editorial, checked by eye against the extracted Lean beside it.

$$\frac{\mathcal{M}_1 \models \text{Morse}(D_1, G_1, \rho_1) \quad \mathcal{M}_2 \models \text{Morse}(D_2, G_2, \rho_2) \quad L_1, L_2 : \text{QBlockLattice (the factor lattices)}}{\mathcal{M}_1 \times \mathcal{M}_2 \models \text{Morse}(D_1 \times D_2, G_1 \times G_2, \rho_1 \times \rho_2)}$$

the two factor judgments enter as derivation premises (judgment-kind edges); the factor lattices enter as certificate data (shared references — the premise judgments' own certificates impose their claims), consulted by the checker's product tie.

QMORSEPRODUCT composes two global judgments along the state-space axis: disjoint variable sets, product arena, product spec graph, product regions. A producer reaches for it exactly where global structure is engineered compositionally — certify each factor subsystem's Morse graph, then take the product — because the alternative (re-discharging the composite through QMORSEDISCHARGE on the composite lattice) recomputes an exponentially larger readout and re-derives the cell map.

The rule is fenced to the deterministic-flow class, and the fence is the rule's own mathematical content: the composite certificate's readout — join-irreducibles, cells, cell order — must be the product of the factor readouts, and for flows that is a theorem (the attractor lattice of a product flow is the coproduct of the factor attractor lattices), while for maps it is false: products of maps exhibit emergent, phase-locked attractors outside the coproduct, so a composite readout computed from factor certificates would misrepresent the product's global structure. For maps the rule must not be derived at all.

What the checker recomputes: wire-disjointness of the factors, the product surgery on graphs and regions, and — on the certificate route — the composite lattice's readout. Facet and transit rows ride along by citation: every composite facet is normal to one factor's axis and its inwardness polynomial is that factor's, the other factor's coordinates entering as free box variables; a factor transit observable still decreases on cell  $\times$  anything, the other factor's drift differentiating it to zero.

The witness-level lemma chain is mechanized in full: the product construction on the semiflow stratum (Semiflow.prod), the factoring lemmas for orbits, limit sets, and chains, the six-clause witness transport (MorseWitness.prod), and the soundness theorem (qMorseProduct\_sound) — unconditional, with no interface hypotheses: from the two factor judgments, the product judgment, on the product arena, product order, and product regions. The bound statements consume neither compactness nor invariance of the arenas (the proof never needed them), and Hausdorffness exactly where the transport says “compact, hence closed.”

**notes** The proof section separates two strata deliberately: the witness-transport argument (compactness, invariance, location, disjointness, cover, order — all coordinate-wise) is elementary and does not consume continuity of time, while the readout-transport theorem that warrants the certificate route is flow-specific. The fence binds the rule as catalogued; the decomposition is recorded so the mechanization and any map-side successor judgment know where the flow hypothesis actually bites. The mechanization respects the split exactly: the bound statements carry the witness-level entailment in full and import nothing of Kalies–Wehbe — the fence's warrant remains at literature strength, where it belongs, since it certifies the canonicity of the certificate-route composite readout rather than the satisfaction-level soundness bound here.

### Lean statement

BernsteinLogic.QtslProduct . qMorseProduct\_sound

statement bound

```
-- QMorseProduct soundness, witness level (thm:qmp-sound; the bind
target). From the two factor judgments — the rule's E1 premises `left,
right : QMorse` — conclude the product judgment on the product arena,
product reachability order, and product regions. UNCONDITIONAL: no
interface hypotheses (contrast the `dcond` family); the analytic
content is the witness transport above. The E2 lattice premises and the
`flows_only` fence's readout-transport warrant (Kalies–Wehbe) live at
the certificate stratum and are deliberately not consumed — see the
module header and the book page's fence remark. -/
theorem qMorseProduct_sound
  (h1 : MorseSat ϕ1 D1 ρ1) (h2 : MorseSat ϕ2 D2 ρ2) :
  MorseSat (ϕ1.prod ϕ2) (D1 ×s D2)
  (fun p : Vtx1 × Vtx2 => ρ1 p.1 ×s ρ2 p.2)
```

BernsteinLogic.QtslProduct . MorseWitness.prod

statement bound

```

/-- Witness transport (lem:qmp-transport): the product family
`M(v, w) := M1(v) × M2(w)`, indexed by the product order, witnesses the
product judgment. Six clauses, each the book paragraph:

* compactness – a product of compacts is compact;
* invariance – coordinate-wise forward invariance, and a product point
rides the pairing of the factor witnesses' complete orbits;
* location – the product of the factor locations;
* disjointness – distinct product vertices differ in some coordinate,
and that factor's disjointness kills the intersection;
* cover – a chain-recurrent product point has chain-recurrent
coordinates (§4), each covered by its factor family;
* order – a product orbit contained in no `M(v, w)` has an uncontained
coordinate; three cases (both uncontained / first only / second
only), the contained coordinate handled by compact-hence-closed and
the closure bound (§3), the  $\alpha$ -side vertex strictly higher in the
product order exactly as the source-to-sink convention demands. -/

## gate-layer coverage of the bound build:

build (lake build (elaboration)) current  
 replay (leanchecker (official kernel replay)) current  
 hardened (safe\_verify (hardened screen)) current

decorrelated (lean4export + nanoda (decorrelated kernel)) current

comparator: none no fixture in the three-implementation comparator harness (compiled / kernel-interpreted / reference-interpreted) exercises this rule.

## HOL4 statement

### NO HOL STATEMENT YET

Absent at the judgment stratum: the HOL4 development's object is the base-kernel checker cone, and no Morse-family definition exists in the ported scripts (verified against the port's definition inventory) — so the satisfaction-judgment semantics this rule's soundness is stated in has no HOL twin to mirror the now-complete Lean mechanization into. A future port has its interface fixed twice over: the witness clauses quoted in the QMORSEDISCHARGE section and the product lemma chain bound here.

## HOL verifier receipts

### NONE

no HOL verification receipt exists for this rule.

## Proof

Genre: core rule (tier 1) — an ordinary mathematical proof at Putnam-exam-solution detail, mechanized *in full*: the accompanying development proves the product construction, the factoring lemmas, the witness transport, and the soundness theorem with no interface hypotheses (contrast the QMORSEDISCHARGE ledger; within the Morse family only QBASIN shares this fully-proved status). The lemma chain below fixed the mechanization's interface in advance, and the formal-anchor table maps each step to the declaration that carries it. The readout-transport theorem of the fence remark is deliberately *not* mechanized: it warrants the canonicity of the certificate-route composite readout, not the witness-level entailment proved here, and remains at literature strength.

**Setting and claim.** Let  $\varphi_1, \varphi_2$  be forward semiflows on Hausdorff metric state spaces  $X_1, X_2$ , with compact forward-invariant arenas  $D_1, D_2$ . The *product semiflow*  $\varphi_1 \times \varphi_2$  on  $X_1 \times X_2$  (with the max metric) flows coordinate-wise:  $\Phi_t(x_1, x_2) = (\Phi_t^1 x_1, \Phi_t^2 x_2)$ ; the semiflow laws hold coordinate-wise. The rule: from  $\mathcal{M}_1 \models \text{Morse}(D_1, G_1, \rho_1)$  and  $\mathcal{M}_2 \models \text{Morse}(D_2, G_2, \rho_2)$ , with disjoint variable sets, conclude

$$\mathcal{M}_1 \times \mathcal{M}_2 \models \text{Morse}(D_1 \times D_2, G_1 \times G_2, \rho_1 \times \rho_2),$$

where  $G_1 \times G_2$  presents the product order  $((v_1, v_2) \geq (w_1, w_2) \text{ iff } v_i \geq w_i \text{ in both coordinates})$  and  $(\rho_1 \times \rho_2)(v_1, v_2) := \rho_1(v_1) \times \rho_2(v_2)$ .

**Lemma R71.1** (orbits, limit sets, and chains factor). (i)  $\gamma = (\gamma_1, \gamma_2)$  is a complete orbit of  $\varphi_1 \times \varphi_2$  iff each  $\gamma_i$  is a complete orbit of  $\varphi_i$ . (ii)  $\omega(\gamma) \subseteq \omega(\gamma_1) \times \omega(\gamma_2)$ , and likewise for  $\alpha$ . (iii) the projection of an  $(\varepsilon, T)$ -chain inside  $D_1 \times D_2$  is an  $(\varepsilon, T)$ -chain inside  $D_i$ ; hence a point chain-recurrent in  $D_1 \times D_2$  has both coordinates chain-recurrent in their arenas.

*Proof.* (i) is the coordinate-wise flow law read in both directions. (ii):  $\gamma([T, \infty)) \subseteq \gamma_1([T, \infty)) \times \gamma_2([T, \infty))$ ; closure of a product is the product of closures; and an intersection of product sets is the product of the intersections — pointwise,  $(x_1, x_2)$  lies in every  $A_T \times B_T$  iff each  $x_i$  lies in every factor set. (iii): under the max metric, factor distance is  $\leq$  product distance, so a single chain step projects to a chain step (jump points project into  $D_i$ , durations are unchanged), and concatenations project to concatenations.  $\square$

**Lemma R71.2** (witness transport). Let  $\{M_1(v)\}_{v \in V(G_1)}$  and  $\{M_2(w)\}_{w \in V(G_2)}$  witness the factor judgments. Then the product family

$$M(v, w) := M_1(v) \times M_2(w),$$

indexed by the product order, witnesses the product judgment.

*Proof.* Six clauses.

**Compactness:** a product of two compact sets is compact.

**Invariance:** forward invariance holds coordinate-wise; and a point  $(x_1, x_2)$  of the product rides the pairing of the factor witnesses' complete orbits through  $x_1$  and  $x_2$  (Lemma R71.1(i)), which stays inside the product set.

**Location:**  $M_1(v) \times M_2(w) \subseteq \rho_1(v) \times \rho_2(w)$ , the product of the factor locations.

**Disjointness:** if  $(v, w) \neq (v', w')$  they differ in some coordinate, say  $v \neq v'$ ; then  $M_1(v) \cap M_1(v') = \emptyset$  makes the products disjoint regardless of the other coordinate.

**Cover:** let  $(x_1, x_2)$  be chain-recurrent in  $D_1 \times D_2$ . By Lemma R71.1(iii) each  $x_i$  is chain-recurrent in  $D_i$ , hence covered by its factor family:  $x_1 \in M_1(v)$ ,  $x_2 \in M_2(w)$  for some  $v, w$ ; so  $(x_1, x_2) \in M(v, w)$ .

**Order:** let  $\gamma = (\gamma_1, \gamma_2)$  be a complete orbit in  $D_1 \times D_2$  contained in no single  $M(v, w)$ . Containment in a product set is coordinate-wise, so — negating “some  $(v, w)$  contains  $\gamma$ ” — either  $\gamma_1$  is contained in no  $M_1(v)$ , or  $\gamma_2$  in no  $M_2(w)$ . Three cases. (both uncontained): the factor order clauses give  $v > v'$  with  $\alpha(\gamma_1) \subseteq M_1(v)$ ,  $\omega(\gamma_1) \subseteq M_1(v')$ , and  $w > w'$  likewise for  $\gamma_2$ ; by Lemma R71.1(ii),  $\alpha(\gamma) \subseteq M(v, w)$  and  $\omega(\gamma) \subseteq M(v', w')$ , with  $(v, w) > (v', w')$  strictly in the product order. ( $\gamma_1$  uncontained,  $\gamma_2 \subseteq M_2(w_0)$ ): the first factor gives  $v > v'$  as above; for the second, range  $\gamma_2 \subseteq M_2(w_0)$  with  $M_2(w_0)$  compact in a Hausdorff space, hence closed, gives  $\alpha(\gamma_2), \omega(\gamma_2) \subseteq \text{cl}(\text{range } \gamma_2) \subseteq M_2(w_0)$ ; so  $\alpha(\gamma) \subseteq M(v, w_0)$ ,  $\omega(\gamma) \subseteq M(v', w_0)$ , and  $(v, w_0) > (v', w_0)$  strictly. (the symmetric case): exchange the roles of the factors. In each case the  $\alpha$ -side vertex is the strictly higher one, as the source-to-sink convention demands.  $\square$

**Theorem R71.3** (soundness of QMORSEPRODUCT, witness level). *If both factor judgments hold, the product judgment holds.*

*Proof.* Choose factor witnesses and apply Lemma R71.2. □

*Remark R71.4* (where the flow hypothesis actually binds — the rule’s fence). Nothing in Lemmas R71.1–R71.2 consumes continuity of time: read over  $\mathbb{N}$ -time systems, the same six clauses transport verbatim, at the same “at most” polarity. The rule is nonetheless fenced to the deterministic-*flow* class, for reasons that live above the witness stratum. The certificate-level discharge route does not consume semantic witnesses: it composes the factor *lattices* (the join-closure of the products of factor blocks, every composite facet’s inwardness polynomial being a factor’s with the other factor’s coordinates riding along as free box variables) and must know that the composite lattice’s recomputed readout — its join-irreducibles, cells, and cell order — is the product of the factor readouts, so that the composite tessellation represents the product dynamics at the resolution the factors certified. For flows this is a theorem: the attractor lattice of a product flow is the coproduct of the factor attractor lattices (Kalies–Wehbe [133]), whose Birkhoff dual [22] is exactly “composite Morse graph = product of factor graphs.” For maps it is false: products of maps exhibit emergent, phase-locked attractors outside the coproduct (Kalies–Wehbe’s counterexample — already visible in the product of two period-two orbits, whose diagonal and anti-diagonal are attractors of the product generated by no product of factor attractors), so a composite readout computed from factor certificates would silently misrepresent the product’s global structure, and the judgment’s ecosystem — which reads a certified Morse graph as the canonical decomposition at the declared resolution — would be poisoned at exactly the canonicity it relies on. Hence the fence: for maps the rule must not be derived at all; for flows the readout-transport theorem is the rule’s semantic import, and it is the reason this core rule carries its own lemma rather than reducing to lattice combinatorics.

*Remark R71.5* (what rides along for free). Two certificate-level transports cost nothing beyond citation, and are worth recording with the rule even though the witness-level proof above does not touch them. *Facet rows*: every internal facet of a composite block is normal to one factor’s axis, and its inwardness polynomial *is* that factor’s facet polynomial — the other factor’s coordinates enter as free box variables, so the composite row’s enclosure data is the factor’s, replicated along the free coordinates. *Transit rows*: if  $\mathcal{A}_1 V \leq -\varepsilon$  on a factor cell, the same  $V$  read on the product satisfies  $\mathcal{A}_{1 \times 2} V = \mathcal{A}_1 V \leq -\varepsilon$  on cell  $\times$  anything — the other factor’s drift differentiates  $V$  to zero. Both ride the same disjointness of the variable sets — the facet rows by weakening alone, the transit rows by weakening plus the product-generator identity  $\mathcal{A}_{1 \times 2}(V \circ \pi_i) = (\mathcal{A}_i V) \circ \pi_i$ , which is the precise content of “differentiates  $V$  to zero.”

*Remark R71.6* (the mechanization consumes no arena hypotheses). The setting above posits compact forward-invariant arenas because that is what arenas are in this catalogue’s ecosystem; the transport itself never uses either property, and the mechanized statements quantify over bare sets  $D_1, D_2$  — strictly more general, and faithful to the witness clauses, which constrain the arena only through the judgments. Hausdorffness is consumed exactly once, where the proof of Lemma R71.2 says “compact in a Hausdorff space, hence closed”; the mechanization takes it as a topological hypothesis over a pseudometric base, which every metric state space satisfies.

*Remark R71.7* (relation to the literature). The rule is the certified face of compositionality results for global dynamics: Kalies–Wehbe [133] prove the attractor-lattice coproduct isomorphism for product flows and delimit it (maps fail; skew products degrade to one-way results), inside the lattice-theoretic program of Kalies–Mischaikow–van der Vorst [131, 132]. The witness-level transport (Lemma R71.2) is elementary Conley theory [47] over products; the observation that its “at most” clauses survive even where the canonical readout does not (Remark R71.4) is exactly why the judgment’s fence is stated at the rule, not at the witness.

## Rule 72. QBLOCKINV (core rule)

### The rule (Steele metanotation)

as realized in the mechanized development; source row: QTSL-rules.toml — *QBlockInv*. The metanotation statement is typeset by hand for notational quality; its mechanized ground truth is the Lean statement below, extracted from the sources at every build of this book and hash-bound. The rule *roster* is machine-checked (every mechanized rule tag round-trips to exactly one catalogue row); the statement *text* is editorial, checked by eye against the extracted Lean beside it.

$$\frac{\begin{array}{c} N : \text{QRegionAtom (the block)} \\ \{F_f \vdash \mathcal{A}\ell_f \geq \varepsilon_f\}_{f \in \text{facets}(N)}, \quad \varepsilon_f \in \mathbb{Q}_{>0} \text{ } (\ell_f \text{ the facet's inward affine coordinate; } F_f \text{ its facet region}) \\ \text{FacetBridge}(\mathcal{M}, D, N, (F_f, \varepsilon_f)_f) \text{ (the bridge package, defined below)} \quad \vdash X_0 \subseteq N \text{ (init\_containment, a single BL leaf)} \end{array}}{\mathcal{M} \models \text{QInvScope}(N, X_0)}$$

each facet-inward row bounds the flow derivative of the facet's inward coordinate ( $\ell_f$ : affine, vanishing on the facet hyperplane, nonnegative on the block's side) below by a strictly positive rational margin, on the facet region  $F_f$ . The displayed **FacetBridge** package comprises: the block realized closed in its arena; each facet region a neighbourhood of its entire facet box, corners included (tangential margin, not merely normal thickening); the per-facet wedge test (one-directional by design); arena invariance ( $N \subseteq D$ ,  $D$  invariant); trajectory continuity and the pointwise-to-integrated row bridge — checker-recomputed or interface-carried per profile (model-class).

**QBLOCKINV** concludes the invariance-scope judgment: the block  $N$  is forward-invariant and encloses the declared initial region. It is the Morse family's workhorse producer — the judgment it mints is consumed by **QBASIN**'s safety factory, by scope-restriction of reach obligations, and as the arena warrant of nested certificates — and its premise kit is minimal: per internal facet of the box-union block, one strictly-inward sign row with explicit positive rational margin (facets on the arena boundary owe nothing), plus one containment row  $X_0 \subseteq N$ .

What the checker recomputes: the block's grid geometry — that the bitmap realizes a closed box-union inside its arena, and the facet-list well-formedness — plus the replay of every row through the base kernel. What would break without each hypothesis: without the sign rows, exit through a facet; without strictness-by-margin, a strict field sign could not be certified through the non-strict enclosure predicates of exact- $\mathbb{Q}$  arithmetic (and the Morse rules that cite the same rows would lose the arguments where strictness is genuinely load-bearing); without the containment row, a start outside the block; without closedness of the realization, the first-exit argument's sup-time step fails.

The mechanization is conditional at a named interface: the bound theorems descend the invariance obligation through a first-exit skeleton (closed block, continuous trajectories, boundary dwell) and a facet-row bridge (integrated growth of the facet observables through a one-directional wedge test), leaving exactly three hypothesis families — the integrated row clause (reachable from the pointwise rows through a mean-value bridge whose surviving content is the profile-level identification of the certified rate with the trajectory-wise derivative), the grid facts of the box-union, and arena invariance (nested citation or model-class warrant, terminating at the whole space). The proof section states the ledger, and why the wedge test must be one-directional (reentrant corners of box-unions).

**notes** The same facet rows serve three consumers — this rule, the lattice membership of the family object, and the Morse discharge's facet arguments — which is the design reason strict margins are mandatory here even though this rule's own conclusion would survive non-strict signs (the proof section's strictness remark).

### Lean statement

BernsteinLogic.QtslSoundness.qBlockInv\_sound

statement bound

```
-- QBlockInv soundness, the M(i) corollary (roster: "2 lines"). The
-- facet rows deliver `hInv` through Lemma M(i) — strict facet-inwardness
-- of the compact box-union block implies forward invariance (gap G1, tier
-- A prose); `init_containment` delivers `hInit`. The rule-level content is
-- the assembly of the `QInvScope` claim. -/
theorem qBlockInv_sound {φ : Semiflow X} {N X0 : Set X}
  (hInv : φ.Invariant N) (hInit : X0 ⊆ N) :
  φ.InvScopeSat N X0
```

BernsteinLogic.QtslDischarge.qBlockInv\_sound\_of\_dwell

statement bound

```
-- QBlockInv soundness with G1 at its residue: the interface fact
-- drops from "the block is invariant" to "boundary points dwell"
-- (G1b — the facet-row bridge). -/
```

```

theorem qBlockInv_sound_of_dwell {φ : Semiflow X} {N X0 : Set X}
  (hN : IsClosed N)
  (htraj : ∀ x, Continuous fun t : ℝ≥0 => φ.flow t x)
  (hdwell : ∀ x ∈ N, x ∈ frontier N →
    ∃ δ : ℝ≥0, 0 < δ ∧ ∀ s ≤ δ, φ.flow s x ∈ N)
  (hInit : X0 ⊆ N) : φ.InvScopeSat N X0

```

BernsteinLogic.QtslDischarge.invariant\_of\_boundaryDwell

statement bound

-- G1's tier-A "first-exit argument", mechanized. A closed region with continuous trajectories is forward-invariant as soon as every BOUNDARY point dwells (stays in the region for some positive time) – interior points dwell by continuity alone. The residue G1b (certified strict facet-inward sign rows  $\Rightarrow$  the boundary dwell) is the polynomial-field bridge, prose tier A, same class as G2.

Proof shape = the note's first-exit: the set of times whose whole prefix stays in `N` is nonempty, closed under the sup (closedness + continuity), and extends past its sup by the dwell at the sup point – so it is unbounded, i.e. all of  $\mathbb{R}_{\geq 0}$ . -/

```

theorem invariant_of_boundaryDwell {φ : Semiflow X} {N : Set X}
  (hN : IsClosed N)
  (htraj : ∀ x, Continuous fun t : ℝ≥0 => φ.flow t x)
  (hdwell : ∀ x ∈ N, x ∈ frontier N →
    ∃ δ : ℝ≥0, 0 < δ ∧ ∀ s ≤ δ, φ.flow s x ∈ N) :
  φ.Invariant N

```

BernsteinLogic.QtslDischarge.HasFacetRows.boundaryDwell

statement bound

-- G1b mechanized at its honest stratum: facet rows + block-in-arena + a forward-invariant arena  $\Rightarrow$  the boundary dwell that `invariant\_of\_boundaryDwell` consumes. Proof shape = the entry half of the interior-entry argument ("interior entry is the same sign fact read forward"): at a boundary point, trajectory continuity confines a short prefix to the wedge neighborhood and every active certified region at once (finitely many); on that prefix each active observable grows from  $\emptyset$  at rate  $\varepsilon_i$  – nonnegative – arena invariance supplies the  $\mathcal{D}$  conjunct, and the wedge test re-admits every prefix point. Inactive facets never appear: the wedge test quotes only active ones. -/

```

theorem HasFacetRows.boundaryDwell {φ : Semiflow X} {D N : Set X}
  (h : φ.HasFacetRows D N) (hND : N ⊆ D) (hD : φ.Invariant D)
  (htraj : ∀ x, Continuous fun t : ℝ≥0 => φ.flow t x) :
  ∀ x ∈ N, x ∈ frontier N →
    ∃ δ : ℝ≥0, 0 < δ ∧ ∀ s ≤ δ, φ.flow s x ∈ N

```

BernsteinLogic.QtslDischarge.qBlockInv\_sound\_of\_facetRows

statement bound

-- QBlockInv soundness from the certificate's facet rows – the composed G1 corollary at the current floor. Standing interface facts, each at its named honest stratum (module header, G1 entry): `hN` and `hND` are grid facts of the block (compact box-union in its arena), `hD` is the model-class arena fact (`invariant\_univ` when the block has no  $\partial D$ -faces), `hrows` carries the G2-class integrated row residue and the R1-class wedge geometry, `htraj` is flow continuity (G3's model-class clause). -/

```

theorem qBlockInv_sound_of_facetRows {φ : Semiflow X} {D N X0 : Set X}
  (hN : IsClosed N)
  (htraj : ∀ x, Continuous fun t : ℝ≥0 => φ.flow t x)
  (hND : N ⊆ D) (hD : φ.Invariant D) (hrows : φ.HasFacetRows D N)
  (hInit : X0 ⊆ N) : φ.InvScopeSat N X0

```

BernsteinLogic.QtslMeanValue.qBlockInv\_sound\_of\_rows

statement bound

-- QBlockInv soundness from pointwise rows – G1's chain at its new floor: per-facet row bounds + profile + wedge geometry + arena invariance + model-class regularity  $\Rightarrow$  `InvScopeSat`. Composes

```

`hasFacetRows_of_rows` into `qBlockInv_sound_of_facetRows`; every
hypothesis is now either R1-recomputable grid geometry, a model-class
fact, exact row arithmetic, or the profile identification. -/
theorem qBlockInv_sound_of_rows {φ : Semiflow X} {D N X0 : Set X}

## Correspondence (Steele display ↔ Lean)

**a bound Lean statement CHANGED since certification — re-review and re-certify** The dictionary below is a reviewer-certified statement of how the mechanized statements above interpret the displayed rule: display metavariable  $\mapsto$  Lean binder, each display hypothesis  $\mapsto$  the premise or side condition carrying it, the display conclusion  $\mapsto$  the goal — with any deliberate difference in width between display and mechanization named outright. Certification is recorded as a hash triple over (the displayed cell, the extracted statement texts, this dictionary's own text); if any of the three changes, this block turns amber until a reviewer re-certifies. The correspondence claim itself remains editorial — reviewer-grade, not machine-checked; its machine-checked successor types each soundness statement against the rule as a structured object, and supersedes this block per rule as it lands.

The displayed judgment  $\mathcal{M} \models \text{QInvScope}(N, X_0) \mapsto$  the goal  $\text{InvScopeSat } N \ X_0 = \emptyset. \text{Invariant } N \wedge X_0 \subseteq N$  — the claim record's denotation verbatim. The five bound statements form one discharge chain: `qBlockInv_sound` (the roster's “two lines”: invariance + containment  $\Rightarrow$  the claim,  $M(i)$  as hypothesis), `_of_dwell` riding `invariant_of_boundaryDwell` (G1 mechanized: closed block + trajectory continuity + boundary dwell  $\Rightarrow$  invariance, the first-exit sup-time argument), and `_of_facetRows` riding `HasFacetRows.boundaryDwell`, the deepest bound form, whose kit is the honest ledger:

- the block  $N : \text{QRegionAtom} \mapsto$  an abstract  $N : \text{Set } X$  with  $hN : \text{IsClosed } N$ : the grid stratum (bitmap realizes a closed box-union in its arena; facet-list well-formedness) is checker-side recompute, and closedness is the one grid fact the bound statements consume — as an explicit hypothesis, not a derived fact.
- facet-inward sign rows  $\mapsto$  `hrows :  $\emptyset. \text{HasFacetRows } D \ N$` : finitely many facet observables  $\ell_i$  with explicit positive margins ( $\forall i, 0 < \varepsilon_i$  — the display's strictness-by-margin, carried exactly), each growing at *integrated* rate  $\geq \varepsilon_i$  along confined prefixes — the pointwise row  $\mathcal{A} \ell \geq \varepsilon$  reaches that form through the G2-class mean-value bridge, outside this bound set — plus the local wedge test, one-directional by design (reentrant corners of box-unions defeat the  $\leftrightarrow$  form), with “ $\partial D$ -faces owe nothing” landing as the wedge test's  $y \in D$  conjunct.
- `init_containment`  $\mapsto$  `hInit :  $X_0 \subseteq N$` , one-to-one, unchanged at every link of the chain.
- the displayed `FacetBridge` package (its contents defined in the flavor text)  $\mapsto$  `htraj` (trajectory continuity — model-class), and the arena pair `hND :  $N \subseteq D + hD : \emptyset. \text{Invariant } D$`  — the certified statement makes the invariance regress explicit (the roster witness names its termination at `invariant_univ`, which is in the module but not this bound set).

Width note: the conditional flag's three named families are visible verbatim in the facet-row statement's binders — the integrated row clause (inside `HasFacetRows`), the grid facts (`hN`, plus the wedge-test geometry carried *inside* `hrows` rather than discharged), and arena invariance (`hD`). The bound set extends past the two-line core (the two blocks below): the row-to-shadow discharge `qBlockInv_sound_of_rows` (module `QtslMeanValue` — pointwise rows reach the integrated shadow form through the interval mean-value bridge, leaving the profile identification `hW` as the sole analytic remainder of the G1 chain), the grid-model discharge `qBlockInv_sound_of_grid` (module `QtslGridGeometry` — grid geometry discharged outright, residues exactly the arena interface and the integrated row clause), and the capstone `qBlockInv_sound_of_pointwiseRows` (grid block + pointwise rows through `FlowDerivOn` to the judgment) are hash-bound, so the conditional residue shrinks to the profile identification plus the arena-invariance interface (its reduction theorems terminate at `invariant_univ`), the facet-neighbourhood interface clause (each certified region  $F_i$  a neighbourhood of every point of its facet box, corners included — the capstone consumes it as an explicit hypothesis) and model-class regularity. One deliberate width inversion: the display's conclusion tie is an unconditional judgment about the model, while `qBlockInv_sound` alone is wider than the rule (any invariant set qualifies); the facet-row form narrows back to certificate-shaped input. No hypothesis in the bound set demands the block be a box-union — the geometry enters only through what the wedge test can actually be discharged for.

## Lean verifier receipts

module `BernsteinLogic.QtslSoundness`; bound build 77005991d61d... (bound from receipt 8130a7a679cef4, 2026-08-04T01:16:06Z). A receipt records that named checking layers accepted a build: (module, compiled-artifact SHA-256, environment SHA-256, checker layers), minted when the checking gate ran; the store receipts attesting the bound build are listed with the layers each run credited. Nothing here asks the reader to trust the store: every layer is an independently runnable program over the quoted sources — rebuild the module and re-run the checkers to reproduce the verdict. Receipts attesting superseded builds credit no layer and are omitted from this rendering (the count of omissions, if any, is noted below).

## HOL verifier receipts

**documentary** hol-strict CLEAN: theory bern\_tr\_t5qdyn, 22 theorems, 0 cheat-tagged, 0 nonstandard axioms (whitelist: DISK\_THM; the four bool axioms) — verification run of 2026-07-22 on an isolated build host, against a content-addressed checkout of the exact sources cited here (git blob d64e1954...); an independent acceptance host ran the same build green at the porting seating (2026-07-21). What is ported is the semiflow-stratum root: the flow law, the invariance and invariance-scope-satisfaction predicates, and the root soundness theorem concluding the scope judgment from invariance plus containment — the exact root the Lean development's satisfaction stratum supplies for this rule. The facet-row bridge (the first-exit skeleton and integrated-growth descent that discharge invariance from the certificate's sign rows) and the grid-geometry recomputation remain Lean-side; the conditional reading of this section's mechanization carries over to the HOL twin unchanged. The facet-sign and containment rows the rule consumes are covered by the ported base checker as before.

HOL receipts are documentary: quoted results of hol-strict runs and census rows from the HOL4 development's build evidence, not minted receipt artefacts. A HOL receipt store (the Lean store's twin) is named future work.

## Proof

Genre: core rule (tier 1) — an ordinary mathematical proof at Putnam-exam-solution detail. The rule's mechanization is *conditional*: the section descends the invariance obligation from an opaque interface fact to three named hypothesis families — integrated facet-row clauses, grid geometry of the block, arena invariance — and the ledger remark at the end states exactly what remains and why. Every hypothesis is used and remarked on; the formal-anchor table maps each step to the Lean declaration that carries it.

**Setting and claim.** Fix a forward semiflow  $\varphi$  on a state space  $X$  ( $\Phi_0 = \text{id}$ ,  $\Phi_{s+t} = \Phi_t \circ \Phi_s$ ; the QBASIN section's setting, which also fixes the QInvScope denotation:  $S$  forward-invariant and  $X_0 \subseteq S$ ). The rule's data: a *block*  $N$  — the realization of a box-union over the certificate's declared rational grid, a compact closed set — sitting in an *arena*  $D \supseteq N$ ; per internal facet of  $N$ , one strictly-inward sign row of the base calculus (a BERNCONe-family sequent asserting the field's normal component points into the block, with an explicit positive rational margin; facets on  $\partial D$  owe nothing); and one containment row  $X_0 \subseteq N$ . The claim: these data warrant  $\text{QInvScope}(N, X_0)$  — established below at the discharged floor, conditional on the named ledger of [Remark R72.9](#).

**Lemma R72.1** (rule-level assembly). *If  $N$  is forward-invariant and  $X_0 \subseteq N$ , then  $\text{QInvScope}(N, X_0)$  holds.*

*Proof.* The judgment is that conjunction. The lemma is stated to fix where the rule-level content ends: everything below descends the invariance conjunct toward the certificate's rows.  $\square$

**Lemma R72.2** (the first-exit skeleton: closed + continuous + boundary dwell  $\Rightarrow$  invariant). *Suppose  $N$  is closed, every trajectory  $t \mapsto \Phi_t x$  is continuous, and every boundary point dwells: for each  $x \in N \cap \partial N$  there is  $\delta > 0$  with  $\Phi_s x \in N$  for all  $0 \leq s \leq \delta$ . Then  $N$  is forward-invariant.*

*Proof.* First, every point of  $N$  dwells: an interior point  $x$  has  $\Phi_0 x = x \in \text{int } N$ , so continuity of the trajectory at time 0 confines a short prefix to  $\text{int } N$  — the dwell hypothesis is needed only at the frontier, which is where the certificate's rows live.

Now fix  $x \in N$  and  $t \geq 0$ , and suppose toward a contradiction that  $\Phi_t x \notin N$ . Consider the set of *prefix-confined times*

$$S := \{u \geq 0 : \Phi_s x \in N \text{ for all } s \leq u\}.$$

$S$  contains 0, and every element of  $S$  is  $\leq t$  (an element  $> t$  would confine time  $t$  itself); throughout, times  $s, u$  range over  $[0, \infty)$ . Let  $T := \sup S \leq t$ . Every time  $s < T$  is confined (it is below some element of  $S$ ). The sup itself is confined: for  $T > 0$  the preimage of  $N$  under the continuous trajectory is closed and contains  $[0, T)$ , hence contains  $T \in \text{cl } [0, T)$ ; for  $T = 0$  it is the hypothesis  $x \in N$ . So  $T \in S$ . But now the dwell at the point  $\Phi_T x \in N$  supplies  $\delta > 0$  with  $\Phi_s(\Phi_T x) \in N$  for  $0 \leq s \leq \delta$ , i.e. (semiflow law)  $\Phi_u x \in N$  for  $T \leq u \leq T + \delta$ ; combined with  $T \in S$  this puts  $T + \delta \in S$ , contradicting  $T = \sup S$  with  $\delta > 0$ .  $\square$

**Remark R72.3** (each skeleton hypothesis is load-bearing). *Closedness*: on  $X = \mathbb{R}$  with  $\Phi_t x = x + t$  and the half-open  $N = [0, 1)$ , every point of  $N$  dwells (interior points by continuity; the one frontier point of  $N$ , namely 0, dwells since  $\Phi_s 0 = s \in [0, 1)$  for small  $s$  — the other frontier point 1 is not in  $N$ ), yet the trajectory from 0 exits: the proof fails exactly at “the sup itself is confined”, which is where closedness is consumed. *Trajectory continuity*: with a discontinuous time-dependence the preimage argument dies and a trajectory may jump across the frontier without ever presenting a boundary point to the dwell hypothesis; in this stratum continuity is a model-class fact (polynomial-drift flows), not a theorem. *Dwell at the frontier*: dropping it re-opens exit through the boundary — it is precisely the obligation the facet rows discharge (next lemma).

**Lemma R72.4** (the facet-row bridge: certified rows  $\Rightarrow$  boundary dwell). *Suppose the certificate supplies, for block  $N$  in arena  $D$ : finitely many facet observables  $\ell_1, \dots, \ell_n : X \rightarrow \mathbb{R}$  (the affine facet polynomials), margins  $\varepsilon_i > 0$ , and certified regions  $F_i$  (boxes around the facets, thickened to full dimension with tangential margin: each  $F_i$  must be a neighbourhood of every point of its facet, corners included — a box thickened only in the normal direction is a neighbourhood of no corner point, and the wedge test below demands one), such that*

(row, integrated form) *along any trajectory segment confined to  $F_i$ ,  $\ell_i$  grows at rate at least  $\varepsilon_i$ : if  $\Phi_s x \in F_i$  for all  $s \leq t$ , then  $\ell_i(\Phi_t x) \geq \ell_i(x) + \varepsilon_i t$ ; and*

(local wedge test) *every frontier point  $x$  of  $N$  has an active set  $A \subseteq \{1, \dots, n\}$  — each active observable vanishing at  $x$ , each active  $F_i$  a neighbourhood of  $x$  — and a neighbourhood  $U$  of  $x$  such that every  $y \in U$  with  $y \in D$  and  $\ell_i(y) \geq 0$  for all  $i \in A$  lies in  $N$ .*

*If moreover  $N \subseteq D$ ,  $D$  is forward-invariant, and trajectories are continuous, then every boundary point of  $N$  dwells.*

*Proof.* Fix  $x \in N \cap \partial N$  with active set  $A$  and wedge neighbourhood  $U$ . The set  $U \cap \bigcap_{i \in A} F_i$  is a finite intersection of neighbourhoods of  $x$ , hence a neighbourhood; continuity of the trajectory at time 0 (where it sits at  $x$ ) confines a prefix  $[0, \delta]$  to it, some  $\delta > 0$ . Now take any  $0 \leq s \leq \delta$  and check the wedge test’s three conditions at  $y = \Phi_s x$ : membership in  $U$  is the confinement; membership in  $D$  is arena invariance applied to  $x \in N \subseteq D$ ; and for each active  $i$ , the whole prefix up to  $s$  is confined to  $F_i$ , so the integrated row gives  $\ell_i(\Phi_s x) \geq \ell_i(x) + \varepsilon_i s = 0 + \varepsilon_i s \geq 0$ , using exactly the activation fact  $\ell_i(x) = 0$ . The wedge test re-admits  $\Phi_s x \in N$ . Inactive facets never appear: the test quotes only active ones.  $\square$

**Theorem R72.5** (soundness of QBLOCKINV, at the discharged floor). *Suppose:  $N$  is closed with  $N \subseteq D$ ;  $D$  is forward-invariant; trajectories are continuous; the certificate’s facet rows satisfy Lemma R72.4’s two clauses; and  $X_0 \subseteq N$ . Then  $\text{QInvScope}(N, X_0)$  holds.*

*Proof.* Lemma R72.4 delivers the boundary dwell; Lemma R72.2 converts it to forward invariance of  $N$ ; Lemma R72.1 assembles the judgment with the containment row.  $\square$

**Remark R72.6** (the wedge test is one-directional by design). At a *reentrant* corner of a box-union block — an inner corner of an L-shape — the block is locally the *union* of two half-spaces  $\{\ell_1 \geq 0\} \cup \{\ell_2 \geq 0\}$ , while the wedge test’s hypothesis set is their *intersection*: the implication “both  $\ell_i \geq 0 \Rightarrow y \in N$ ” holds (the intersection sits inside the union), but its converse is false there — points of  $N$  with one active observable negative exist on the other branch. The biconditional form of the test would therefore be unsatisfiable at reentrant corners, while the one-directional form is exactly what the first-exit argument consumes (Lemma R72.4 never needs to *characterize* the frontier, only to re-admit prefix points). A certificate whose rows are jointly unsatisfiable at a boundary point — checkerboard blocks touching at a corner and demanding opposite strict signs there — simply makes the bridge’s hypotheses unfulfillable: soundness only consumes what is given.

**Remark R72.7** ( $\partial D$ -faces owe nothing; the arena regress terminates). Facets of  $N$  on the arena boundary carry no rows: in Lemma R72.4 they enter only through the conjunct  $y \in D$ , which arena invariance supplies. The arena’s own invariance is either a nested QInvScope citation (a chart sub-block certified by its own facet rows — this same rule, one level up) or the model-class fact that a chart’s denotation confines trajectories to its domain; the regress terminates at the whole space, which is invariant vacuously.

**Remark R72.8** (strictness of the margins: where it is and is not consumed). The invariance conclusion of this section survives  $\varepsilon_i = 0$ : the integrated clause then says  $\ell_i$  is non-decreasing along confined segments, and growth-from-zero still yields  $\ell_i \geq 0$  — consistent with the classical invariance theorem (Nagumo [187]), which needs only subtangentiality. The explicit positive rational margin is nonetheless mandatory in the certificate convention, for two reasons that live outside this section. First, exactness: a *strict* field sign cannot be certified directly by the non-strict enclosure predicates of the base calculus; “non-strict row on  $\mathcal{A}\ell - \varepsilon$  with explicit  $\varepsilon > 0$ ” is how strictness becomes checkable in exact  $\mathbb{Q}$ . Second, the same rows are consumed by the Morse-family rules, where strictness is genuinely load-bearing — no orbit rides a facet, distinct fibres’ invariant parts are disjoint, and the facet margin bounds admissible chain jumps (“strictness pays a second time”; see the QMORSEDISCHARGE section’s ledger). A margin quietly dropped to zero would leave this rule’s conclusion intact and break those.

**Remark R72.9** (the hypothesis ledger — what remains, named). The chain above discharges the rule’s invariance obligation down to three hypothesis families, and the rule’s Lean column renders with the hypothesis-flavoured check because of exactly these:

(a) *the integrated row clause: discharged, and bound.* The certificate’s rows are pointwise: per facet box, a base-calculus sequent bounding the field’s certified rate,  $\mathcal{A}\ell_i \geq \varepsilon_i$  (the generator  $\mathcal{A} = f \cdot \nabla$  of the deterministic model class). Lemma R72.4 consumes the *integrated* clause along trajectory segments. The bridge between them is one-variable calculus — a mean-value argument along the trajectory, mechanized and bound in this edition (anchor table) — and its surviving analytic content is the identification of the certified polynomial rate with the trajectory-wise derivative on the region: a model-class profile warrant (for smooth flows the identification is literal; switched and hybrid profiles replace it by one-sided derivative bounds, which is their own seam, deliberately not this section’s).

(b) *grid geometry of the block: closed for grid blocks, and bound — except one interface clause.* Closedness of  $N$ ,  $N \subseteq D$ , the vanishing of each facet observable on its facet box, and the wedge re-admission implication are finite geometry of the box-union over its declared rational grid — recomputable combinatorics, proved outright for grid blocks in the grid-geometry module and bound in this edition (anchor table), end-to-end through the capstone that takes grid block plus pointwise row bounds to the concluded judgment. The one geometric clause that stays interface-level even there: each certified region  $F_i$  must be a neighbourhood of every point of its facet box, corners included — the tangential-margin requirement of Lemma R72.4 — which the capstone consumes as a hypothesis on the certificate’s regions rather than proving from the boxes. The interface-level theorems above remain stated with (b) as hypotheses, which is what the general (non-grid) reading consumes.

(c) *arena invariance.* As in the regress remark: nested citation, or model-class warrant, terminating at the whole space.

None of the three is an opaque dynamical assumption; each names a specific fact with a specific owner — (a) the profile stratum, (b) the checker’s recompute (and the grid module), (c) the arena’s own certificate. That is the sense in which this core rule is *conditionally* mechanized: the cited theorems are sorry-free, and their hypotheses are the ledger above.

**Remark R72.10** (relation to the literature). The block-with-inward-facets certificate is the exact-arithmetic descendant of Conley theory’s isolating blocks [48]: compact sets whose boundary behaviour is transverse, so that dynamical claims reduce to boundary sign checks. The invariance argument itself is Nagumo’s theorem [187] in first-exit form, specialized to polyhedral sets, where the subtangentiality condition becomes finitely many polynomial sign rows — the form set-invariance control has long exploited [23]. What the certificate stratum adds is the discipline: strict signs via non-strict predicates with exact rational margins (Remark R72.8), and a one-directional wedge test chosen so that box-union (nonconvex) blocks are admissible without any frontier characterization (Remark R72.6).

## Rule 73. QLATTICEINV (alias for QBLOCKINV)

### The rule (Steele metanotation)

as realized in the mechanized development; source row: QTSL-rules.toml — *QLatticeInv*. The metanotation statement is typeset by hand for notational quality; its mechanized ground truth is the Lean statement below, extracted from the sources at every build of this book and hash-bound. The rule *roster* is machine-checked (every mechanized rule tag round-trips to exactly one catalogue row); the statement *text* is editorial, checked by eye against the extracted Lean beside it.

$$\frac{L : \text{QBlockLattice} \quad C \text{ (downset, a cell-set; membership and down-closedness recomputed)} \quad \mathcal{M} \models \text{QInvScope}(\bigcup_{i \in C} \text{blocks}(\text{emb } i), X_0) \text{ (the cited QBLOCKINV conclusion)} \quad \vdash X_0 \subseteq \bigcup \downarrow C \text{ (init\_containment)}}{\mathcal{M} \models \text{QInvScope}(\bigcup \downarrow C, X_0)}$$

QLATTICEINV is the family object's invariance alias: any down-closed cell-set  $C$  of the recomputed readout names an invariant region  $\bigcup \downarrow C$ , and the rule concludes its invariance-scope judgment by citation — the unpacking is a single QBLOCKINV application whose block is the lattice member realizing the down-set (existence by join-closure) and whose facet rows are that member's own, already present in the family object. No row is re-proven; the producer merely selects which down-set encloses the initial region away from the avoid sets.

What the checker recomputes: membership of the realization in the lattice, and down-closedness of  $C$  in the recomputed cell order — readout facts, not dynamics. What would break without them: a cell-set that is not down-closed names a region orbits can leave (an orbit descends the cell order out of it), and the exactness identity between the down-set's cell union and the member's realization fails — already on a two-member chain: the top member alone is not down-closed, and its cell omits everything the bottom member contributes.

Mechanization state, plainly: the bound statements below are the exactness identity and the soundness corollaries, at both semantic strata (module BernsteinLogic.QtslLatticeInv). *qLatticeInv\_exact* proves the identity that makes the respelling exact — for down-closed  $C$ , the union of  $C$ 's cells equals the union of its join-irreducible realizations — by the discharge chain's own well-founded descent through lower covers (*exists\_cellMem\_subset*, over the same descent rows the eventual-member interface consumes — rows that assume no distributivity, plus one row this alias adds: cell inside member, the readout closure half's set-level shadow). One sharp point, because the page's classical route consumes distributivity: the mechanized route consumes none, and the row pack does not encode join-primality — absorption-positive families satisfy every row, and the bound (union-form) identity holds in them regardless — because the descent runs inside a single witnessed member of  $C$  and never forms the join. The join-form reading (the union as the member  $N_C$ 's realization) costs exactly join-realizes-as-union, the checker's recomputed membership of the down-set's realization, strictly weaker than distributivity; that recompute is also what refuses the diamond-lattice witness when its top is realized past the atoms' union. The corollaries *Semiflow.qLatticeInv\_sound* / *Behavior.qLatticeInv\_sound* (and their *\_of\_blockInv* end-to-end forms) are  $\text{sound}_A = \text{sound}_T \circ \text{unpack}$  through the cited QBLOCKINV conclusion, delivered as judgment-level cargo. Unconditional: the lattice rows are the checker's recomputed readout facts entering as theorem parameters (R1 shadows), and join-closure membership of the down-set's realization is deliberately *not* consumed — with down-closedness consumed and the cited member judgment supplied, the entailment holds for the bare cell union, so the rule is sound a fortiori with the checker's extra side condition. The payload-level unpack elaborator is bound beside the corollaries (as with the sibling extension rules; module BernsteinLogic.QtslElaborators): *LatticeInvPayload* reifies the wire payload — the leg-7 row pack, the down-set, the containment row — *LatticeInvPayload.unpack* is the verified transport onto the QBLOCKINV payload (block := the down-set's realization; the containment row rewritten along the exactness identity; facets a citation, never payload data), and the *qLatticeInv\_sound\_elab* pair is  $\text{sound}_A = \text{sound}_T \circ \text{unpack}$  with *qBlockInv\_sound* as the literal  $\text{sound}_T$ , at both semantic strata. The tier is flagged, not forced: if registry-backed citation of the member's rows is ruled heavier than the alias criterion allows, the rule reclassifies as admissible with all machinery unchanged.

**notes** The warrant for the reading — once an orbit enters a lattice member it never leaves, so visited cells descend the cell order and down-sets are forward-invariant — is the same orbit combinatorics the Morse discharge's order clause rests on, consumed here at its easy end.

### Lean statement

BernsteinLogic.QtslLatticeInv . *qLatticeInv\_exact*

statement bound

```
-- **prop:qli-exact, the exactness identity.** For a down-closed cell-set
`C`, the union of the cells of `C` equals the union of the realizations of
`C`'s join-irreducible members — the realization of the display's member
`N_C = v C` (join = union in the union-closed family object). The  $\supseteq$  half
is leg 7's well-founded descent through lower covers
(`Semiflow.exists_cellMem_subset`): a member point lands in the cell of a
join-irreducible below it, and down-closedness (through `horder`) pins
that cell inside `C`. The  $\subseteq$  half is `hcellSub`, cell inside member. This
is what makes the alias's respelling exact rather than merely ` $\supseteq$ '. -/
```

## Correspondence (Steele display $\leftrightarrow$ Lean)

**reviewer-certified against the displayed texts** The dictionary below is a reviewer-certified statement of how the mechanized statements above interpret the displayed rule: display metavariable  $\mapsto$  Lean binder, each display hypothesis  $\mapsto$  the premise or side condition carrying it, the display conclusion  $\mapsto$  the goal — with any deliberate difference in width between display and mechanization named outright. Certification is recorded as a hash triple over (the displayed cell, the extracted statement texts, this dictionary's own text); if any of the three changes, this block turns amber until a reviewer re-certifies. The correspondence claim itself remains editorial — reviewer-grade, not machine-checked; its machine-checked successor types each soundness statement against the rule as a structured object, and supersedes this block per rule as it lands.

The displayed judgment  $\mathcal{M} \models \text{QInvScope}(\bigcup \downarrow C, X_0) \mapsto \text{InvScopeSat}(\bigcup i \in C, \text{cells } i) X_0$ , at BOTH semantic strata (Semiflow./Behavior.qLatticeInv\_sound — the exactness identity is dynamics-free, so the behavioural transport is verbatim). The alias's entire content is qLatticeInv\_exact: for down-closed  $C$  ( $\text{hdc} : \text{IsLowerSet } C$  — the R1 down-closedness recompute as a binder), the union of  $C$ 's cells EQUALS the union of its join-irreducible realizations — the member  $N_C$ 's realization exactly where the checker's membership recompute holds (join realizes as union; the bound statement is on the bare union and consumes no distributivity) — so the respelling is exact, not merely one-sided.

- the E2 lattice  $L \mapsto$  the Birkhoff row pack, abstract:  $\text{hJoin}$  (every block point lands in a join-irreducible below it),  $\text{hcover}$  (strict lower covers),  $\text{hcellsSup}$  ( $\text{cell} \supseteq \text{member}$  minus cover),  $\text{horder}$  (order reflects realization inclusion) — byte-identical to the Morse discharge's eventual-member interface: no lattice structure is minted, the rows ARE the interface — plus the one row new to this alias,  $\text{hcellSub}$  ( $\text{cell} \subseteq \text{member}$ : the readout closure half's set-level shadow).
- the cited QBlockInv premise  $\mapsto \text{hMember} : \text{InvScopeSat}(\bigcup i \in C, \text{blocks } (\text{emb } i)) X_0$  — judgment-level cargo on the member's realization (the qBasin\_sound precedent: facet rows live in the cited node, never here);  $\text{\_of\_blockInv}$  composes the target in end-to-end (its  $\text{hInv/hInit}$  pair is qBlockInv\_sound's kit, the containment row transported across the identity).
- $\text{init\_containment} \mapsto \text{hInit} : X_0 \subseteq \bigcup i \in C, \text{cells } i$ , stated on the alias's displayed region.
- $\text{member\_subset\_cells\_le}$  exposes the page's “cells tile members” fact at the principal down-set — bound because the proof section names it.

Width note: the module is topology-free and dynamics-free except through the cited judgment —  $\text{cells/blocks}$  arbitrary set families over an abstract ordered index; the grid realization of the lattice is R1 territory, strictly wider in the safe direction. Module row bound to an attested build (the receipt provenance is recorded in the bindings).

## Lean verifier receipts

module BernsteinLogic.QtslLatticeInv; bound build 467dc57e1c30... (bound from receipt 98755f4d8dbefb10, 2026-07-21T04:48:40Z). A receipt records that named checking layers accepted a build: (module, compiled-artifact SHA-256, environment SHA-256, checker layers), minted when the checking gate ran; the store receipts attesting the bound build are listed with the layers each run credited. Nothing here asks the reader to trust the store: every layer is an independently runnable program over the quoted sources — rebuild the module and re-run the checkers to reproduce the verdict. Receipts attesting superseded builds credit no layer and are omitted from this rendering (the count of omissions, if any, is noted below).

| receipt          | minted               | layers                             | status  |

### gate-layer coverage of the bound build:

build (lake build (elaboration)) **current**

replay (leanchecker (official kernel replay)) **current**

hardened (safe\_verify (hardened screen)) **current**

decorrelated (lean4export + nanoda (decorrelated kernel)) **current**

**comparator: none** no fixture in the three-implementation comparator harness (compiled / kernel-interpreted / reference-interpreted) exercises this rule.

## HOL4 statement

**NO HOL STATEMENT YET**

Absent at the judgment stratum: no judgment-stratum definition exists in the ported base-kernel checker scripts (verified against the port's definition inventory), so the satisfaction-level witnesses — now mechanized on the Lean side (module `QtslLatticeInv`, the entry's bound statements) — have no HOL twin to mirror them. The target rule's rows (facet signs, containment) ARE covered by the ported checker.

**HOL verifier receipts****NONE**

no HOL verification receipt exists for this rule.

**Proof**

Genre: alias rule (tier 3) — a respelling template. An alias owes the book five artefacts: the verified  $1 \rightarrow 1$  unpack function, the filled-in application of the target rule, the payload-transport table, the exact algebraic identity that makes the respelling correct, and the soundness corollary through the target rule's lemma. All five are present — the filled-in application, the transport table, the exactness identity and the soundness corollary mechanized and bound in the entry (`qLatticeInv_exact`, Proposition [R73.4](#); the `qLatticeInv_sound` family, Proposition [R73.6](#), at the semiflow *and* behavioural strata), and — now that the extension certificate schema exists — the verified payload-level unpack function itself, `LatticeInvPayload.unpack` with its factoring pair (the remark below names the bound functions). (Tier flag, carried honestly: the unpack cites facet rows through the checker's recomputed lattice readout — if registry-backed citation is ruled heavier than the alias criterion allows, the rule reclassifies as admissible with all machinery unchanged.)

*Remark R73.1* (the payload-level elaborator, mechanized). The *semantic* content of this page is bound in the entry: `qLatticeInv_exact` is Proposition [R73.4](#) (over the discharge chain's own Birkhoff rows — no lattice structure is minted), and the `qLatticeInv_sound` family is Proposition [R73.6](#) in both its through-the-target and end-to-end forms, at both semantic strata. The payload-level elaborator — previously this page's one absent artefact, held back until the extension certificate schema existed — is bound with it, as with the sibling extension rules: `LatticeInvPayload` (module `BernsteinLogic.QtslElaborators`) reifies the rule's wire payload — family object as the leg-7 row pack, down-set, containment row — and `LatticeInvPayload.unpack` takes it to the single `QBlockInv` payload of Recipe [R73.3](#) (`BlockInvPayload`: `block` := the down-set's realization, the containment row transported along Proposition [R73.4](#); facets are a citation, entering the factoring theorems as the cited node's invariance, never as payload data). The factoring pair `Semiflow.qLatticeInv_sound_elab / Behavior.qLatticeInv_sound_elab` is  $\text{sound}_A = \text{sound}_T \circ \text{unpack}$  with `qBlockInv_sound` as the literal  $\text{sound}_T$ , applied to the unpacked payload. The checker-side ingredients (membership of the down-set's realization in the lattice, down-closedness of the cell-set) are recomputed side conditions, already specified with the rule; the mechanization deliberately consumes the down-closedness and leaves the membership fact checker-side (with down-closedness consumed and the cited member judgment supplied, soundness holds for the bare cell union, a fortiori with the extra condition).

**Recipe R73.2** (the alias template). An alias rule  $A$  is warranted by a verified function  $\text{unpack} : \text{Step}_A \rightarrow \text{Step}_T$  into the payload of a *single* target node  $T$ , such that the  $A$ -node and its image conclude the same judgment from the same premises: one node  $\rightarrow$  one node, payload transported, nothing derived. Soundness is then a corollary,  $\text{sound}_A = \text{sound}_T \circ \text{unpack}$ .

**The rule.** The certificate supplies the family object (the block lattice of the `QMORSEDISCHARGE` section, with its recomputed readout: join-irreducible members  $b$ , lower covers  $b^-$ , cells  $T(b) := \text{cl}(b \setminus b^-)$ , the induced cell order), a cell-set  $C$  of join-irreducibles that is *down-closed* in the cell order, and one containment row  $X_0 \subseteq \bigcup \downarrow C$ . It concludes  $\text{QInvScope}(\bigcup \downarrow C, X_0)$ , writing  $\bigcup \downarrow C$  for the union of the cells of  $C$ .

**Recipe R73.3** (the filled-in application — `QLATTICEINV` rewritten *into* the `QBLOCKINV` instance). Let  $N_C := \bigvee_{b \in C} b$  — the lattice join of the down-set's members, itself a member of the family object by join-closure. The `QLATTICEINV` node rewrites to the single `QBLOCKINV` application

$$\frac{\begin{array}{l} N_C \text{ (the member: block data from the family object)} \\ \{ \vdash \text{ facet-inward sign rows of } N_C \} \text{ (cited from the family object, byte-identical)} \\ \vdash X_0 \subseteq N_C \text{ (the rule's own containment row, rewritten along Proposition \a href\#R73.4)} \end{array}}{\mathcal{M} \models \text{QInvScope}(N_C, X_0)} \quad \text{QBLOCKINV}$$

and the conclusion is the alias's conclusion *on the nose* by Proposition [R73.4](#):  $N_C = \bigcup \downarrow C$  as regions. Every internal facet of  $N_C$  already carries its sign row in the family object — membership of  $N_C$  in the lattice is exactly the checker's recomputed side condition, and no row is re-proven.

**Proposition R73.4** (the exactness identity). *For a down-closed set  $C$  of join-irreducibles,*

$$\bigcup_{b \in C} T(b) = \bigvee_{b \in C} b \quad (\text{equality of realizations}).$$

*Proof.* Two readout facts, one lattice fact. (*cells tile members*) Every member  $N$  of the lattice is the union of the cells of the join-irreducibles below it,  $N = \bigcup \{T(b) : b \in J, b \subseteq N\}$ : downward induction along lower covers —  $T(b)$  is by definition what  $b$  adds over  $b^-$ , so peeling cells descends through the lattice and exhausts  $N$ . (*Birkhoff exactness*) In a finite *distributive* lattice (a lattice

of regions closed under union and intersection — a ring of sets — qualifies) the map  $N \mapsto \{b \in J : b \subseteq N\}$  is an isomorphism onto down-closed sets of join-irreducibles [22]; for down-closed  $C$  the join  $N_C$  then satisfies  $\{b \in J : b \subseteq N_C\} = C$ . Distributivity — join-primality of the irreducibles — is what forbids the join from absorbing new join-irreducibles, and it is not decoration: in the diamond lattice  $M_3$ , two of the three atoms form a down-closed set of join-irreducibles whose join absorbs the third. Substituting the second fact into the first:  $N_C = \bigcup_{b \in C} T(b)$ . (Where each half lives: the tiling is the readout’s own construction, recomputed by the checker per certificate; the isomorphism is the one classical fact, and down-closedness of  $C$  is the recomputed side condition that makes the identity exact rather than merely  $\supseteq$ .) *Mechanization note, the honest disanalogy, adjudicated against the descent:* `qLatticeInv_exact` binds the identity in union form —  $\bigcup_{b \in C} T(b) = \bigcup_{b \in C} b$  as realizations, the right side the bare union over the down-set — and proves it from the row pack alone: *no distributivity hypothesis is consumed*, and none is encoded, since the rows are satisfiable in absorption-positive families. The route never forms the join: each point of the union arrives with a witnessing member  $b \in C$ ; the well-founded descent through lower covers (the discharge chain’s `exists_cellMem_subset`) runs *inside that one member*, landing the point in the cell of a join-irreducible  $b' \subseteq b$ ; and the pin-step is two rows — the induced-order binding `horder` turns  $b' \subseteq b$  into  $b' \leq b$  in the cell order, and down-closedness closes  $b' \in C$ . Join-primality forbids absorption below the join; the descent never visits the join, so the prohibition is sidestepped, not re-proven. What distributivity carries is therefore only the display seam — reading the bare union as the realization of the member  $N_C = \bigvee C$  — and the seam consumes less than the full hypothesis: it needs exactly join-realizes-as-union, which is the checker’s recomputed membership of the down-set’s realization (a member that is a union of members is their least upper bound), a consequence of the ring-of-sets structure strictly weaker than distributivity (union-closed absorption-positive families exist: there the identity holds in *both* forms while the classifying map still fails). The  $M_3$  witness above, realized as sets — atom realizations  $\{1\}, \{2\}, \{3\}$ , top  $\{1, 2, 3\}$ ,  $C$  the first two atoms — separates the strata cleanly: every row holds, the union form holds ( $\{1, 2\} = \{1, 2\}$ ), the join form fails ( $\{1, 2\} \neq \{1, 2, 3\}$ ), and it is the membership recompute that refuses. Nothing mechanized rests on the classical citation; it remains as warrant genealogy for this proof’s route.  $\square$

**Recipe R73.5** (payload transport — field for field).

| QLatticeInv payload                           | QBlockInv payload                                                                   |
|-----------------------------------------------|-------------------------------------------------------------------------------------|
| family object + down-set $C$<br>(no own rows) | block $N_C = \bigvee C$ (member, by join-closure)                                   |
| init_containment                              | facets := $N_C$ ’s rows, cited from the family object                               |
| conclusion region $\bigcup \downarrow C$      | init_containment (rewritten along Proposition R73.4: $\bigcup \downarrow C = N_C$ ) |
|                                               | conclusion region $N_C$ (Proposition R73.4)                                         |

The checker’s recomputed side conditions at the alias:  $C$  down-closed in the recomputed cell order, and  $N_C$  a member whose facet rows are all present — both facts about the readout, not about the dynamics.

**Proposition R73.6** (soundness corollary, through the target). *If the family object’s rows are valid and  $X_0 \subseteq \bigcup \downarrow C$ , then — under the QBlockInv section’s standing hypotheses (its conditional ledger, applied to the member  $N_C$ ) —  $\text{QInvScope}(\bigcup \downarrow C, X_0)$  holds.*

*Proof.* The member  $N_C$  is a strictly facet-inward compact block of the family object, so the QBlockInv section’s theorem chain applies to it verbatim (its rows *are* rows of the family object); the conclusion transports along Proposition R73.4. Mechanized, this proposition is one composition,  $\text{sound}_{\text{QLatticeInv}} = \text{sound}_{\text{QBlockInv}} \circ \text{unpack}$  — there is no other content, which is the alias genre working as intended: the through-the-target form (`Semiflow.qLatticeInv_sound / Behavior.qLatticeInv_sound`) takes the cited node’s `QInvScope` conclusion as judgment-level cargo and rewrites along the identity; the end-to-end form (`_of_blockInv`) composes through `qBlockInv_sound` verbatim. Both strata are covered because the identity is dynamics-free — the alias transports at every semantics for free.  $\square$

**Remark R73.7** (why the rule earns its keep). Down-closed cell-sets are the invariant enclosures the Morse readout offers for free: once an orbit enters a member it never leaves, so the sequence of cells it visits is non-increasing in the cell order, and the down-set of any initial cell-set is forward-invariant and encloses the reachable set. The alias turns each such enclosure into a one-node citation — the member’s rows already exist in the family object — where a direct proof would re-derive facet rows the certificate already carries. Downstream, the minted `QInvScope` judgment feeds QBASIN’s safety factory and scope-restriction of reach obligations, which is where the row-count payoff compounds.

| proof step                                    | formal anchor                                                                                                                                                                                                                                                          |

## Rule 74. QBASIN (core rule)

### The rule (Steele metanotation)

as realized in the mechanized development; source row: `QTSL-rules.toml` — *QBasin*. The metanotation statement is typeset by hand for notational quality; its mechanized ground truth is the Lean statement below, extracted from the sources at every build of this book and hash-bound. The rule *roster* is machine-checked (every mechanized rule tag round-trips to exactly one catalogue row); the statement *text* is editorial, checked by eye against the extracted Lean beside it.

$$\frac{\mathcal{M} \models \text{QInvScope}(S, X_0) \quad \{\vdash S \cap \llbracket \beta_j \rrbracket = \emptyset\}_j \text{ (avoid\_disjoint rows)}}{\mathcal{M}, x_0 \in X_0 \models \text{SProbGE}(1, \text{PAlways}(\text{SNot } \beta_j))}$$

the invariance premise is deliberately the `textsQInvScope` judgment and not the Morse-graph judgment: basin avoidance consumes invariance of  $S$  from  $X_0$  alone, and asking the stronger judgment would couple the rule to machinery its soundness never uses.

QBASIN is the campaign rule: safety atoms by citation. From one invariance-scope judgment and one disjointness fact per avoid region, it concludes the safety-shaped region judgment `SProbGE(1, PAlways(SNot  $\beta$ ))` (surface syntax  $P_{\geq 1}[G \neg \beta]$ ) on the scope's init region — the deterministic reading, with no probabilistic machinery: for the deterministic model class the certified claim is universal avoidance, and no supermartingale certificate is synthesized or needed. The economics are the point: the invariance judgment is proved once (typically by `QBLOCKINV` or `QLATTICEINV`, whose facet rows already live in the family object), and each additional avoid region costs exactly its own disjointness rows and nothing else — the invariance side is cited, never re-certified, even when the regions are taken jointly (the batch theorem).

What the checker recomputes: the conclusion tie (the cited judgment's region and init fields equal the rule's own), plus the per-box disjointness sign rows, or the grid bookkeeping when the avoid region is cell-aligned. What would break without each hypothesis: without invariance, a trajectory exits the scope and reaches the avoid set (the proof section's drift counterexample); without the containment, failure at time zero; without disjointness, failure at time zero inside the scope.

The premise is deliberately the invariance judgment and NOT the global Morse judgment: recurrence structure alone implies no enclosure of the init region — an orbit may transit the avoid set en route to its Morse set. Basin-minted and battery-minted safety atoms are type-identical conclusions, so downstream citations consume either producer indifferently; keying on provenance is forbidden by design.

This is the one Morse-family rule whose mechanization is unconditional: the cited theorems are proved outright, with no interface hypotheses.

**notes** The probability-one costume (`SProbGE(1, ·)`) matters for composition: the conclusion lands in the same judgment form the probabilistic batteries mint, so tower citations, boolean combination at the root, and the assume-guarantee spine consume deterministic and stochastic safety atoms through one interface.

### Lean statement

`BernsteinLogic.QtslSoundness.qBasin_sound`

statement bound

```
-- QBasin soundness (roster: "3 lines against the Morse note's lemma
corpus"; axioms note §3.5) — FULLY PROVED, no interface facts. Premises:
the cited `QInvScope` judgment (the E1 edge `QBasin/inv`) and the
avoid-disjointness fact (`QBasin/avoid_disjoint`'s rows). Conclusion:
the safety-shaped `QRegionSat` on the scope's init region. Note the
invariance premise arrives as judgment-level cargo — the certificate-
level fact `QInvScope` carries — which is why no dynamics beyond the
semiflow algebra is consumed here (the roster's §4.6 correction: the
premise is NOT the `QMorse` judgment). -/
theorem qBasin_sound {φ : Semiflow X} {S X0 B : Set X}
  (hscope : φ.InvScopeSat S X0) (hAvoid : S ∩ B = ∅) :
  φ.SafetySat X0 B
```

`BernsteinLogic.QtslSoundness.qBasin_batch`

statement bound

```
-- The batch-factory payoff, mechanized ("one family object, many
G-judgments, no new rows" — zero new rows per additional `β` after the
first containment): one invariant scope
discharges every avoid-region at the price of its own disjointness fact
alone — even jointly. -/
```

```

theorem qBasin_batch {φ : Semiflow X} {S X0 : Set X} {J : Type*}
  {B : J → Set X} (hscope : φ.InvScopeSat S X0)
  (hAvoid : ∀ j, S ∩ B j = ∅) :
  φ.SafetySat X0 (⋃ j, B j)

```

## Correspondence (Steele display ↔ Lean)

**a bound Lean statement CHANGED since certification — re-review and re-certify** The dictionary below is a reviewer-certified statement of how the mechanized statements above interpret the displayed rule: display metavariable  $\mapsto$  Lean binder, each display hypothesis  $\mapsto$  the premise or side condition carrying it, the display conclusion  $\mapsto$  the goal — with any deliberate difference in width between display and mechanization named outright. Certification is recorded as a hash triple over (the displayed cell, the extracted statement texts, this dictionary's own text); if any of the three changes, this block turns amber until a reviewer re-certifies. The correspondence claim itself remains editorial — reviewer-grade, not machine-checked; its machine-checked successor types each soundness statement against the rule as a structured object, and supersedes this block per rule as it lands.

Both statements are read against the abstract model class: the display's model  $\mathcal{M}$  is any forward semiflow  $\varphi$  (Semiflow X) on a bare state type; the v1 model class realizes it, and nothing in either statement consumes the realization.

- $S, X_0$  (the scope's region and init region)  $\mapsto$  the binders  $S \ X_0 : \text{Set } X$ ; the avoid predicate's extent  $\llbracket \beta_j \rrbracket \mapsto B : \text{Set } X$  in  $\text{qBasin\_sound}$ , and the indexed family  $B : J \rightarrow \text{Set } X$  in  $\text{qBasin\_batch}$  (the display's  $j$ -indexed premise row, taken jointly).
- premise  $\text{inv} : \text{QInvScope}(S, X_0) \mapsto \text{hscope} : \varphi.\text{InvScopeSat } S \ X_0$  — definitionally the conjunction of forward invariance of  $S$  and  $X_0 \subseteq S$ , the judgment's two clauses.
- each  $\text{avoid\_disjoint}$  row  $\vdash S \cap \llbracket \beta_j \rrbracket = \emptyset \mapsto \text{hAvoid} : S \cap B = \emptyset$  (batch:  $\forall j, S \cap B j = \emptyset$ ).
- conclusion  $\mathcal{M}, x_0 \in X_0 \models \text{SProbGE}(1, \text{PAlways}(\text{SNot } \beta_j)) \mapsto$  the goal  $\varphi.\text{SafetySat } X_0 \ B$ : every trajectory from  $X_0$  avoids  $B$  at every forward time — the deterministic probability-one reading of the displayed judgment.  $\text{qBasin\_batch}$  concludes  $\varphi.\text{SafetySat } X_0 (\bigcup_j B j)$ , which yields the displayed per- $j$  family of conclusions by monotonicity.

Width note: the display's E1 annotation, glossed by the flavor text (the premise is the invariance judgment, *not* the Morse judgment), is enforced by type rather than by hypothesis —  $\text{qBasin\_sound}$  consumes an  $\text{InvScopeSat}$  fact and nothing of Morse shape fits that premise slot. No hypothesis of either statement is unused, and neither statement is wider than the displayed rule.

## Lean verifier receipts

module BernsteinLogic.QtslSoundness; bound build 77005991d61d... (bound from receipt 8130a7a7a679cef4, 2026-08-04T01:16:06Z). A receipt records that named checking layers accepted a build: (module, compiled-artifact SHA-256, environment SHA-256, checker layers), minted when the checking gate ran; the store receipts attesting the bound build are listed with the layers each run credited. Nothing here asks the reader to trust the store: every layer is an independently runnable program over the quoted sources — rebuild the module and re-run the checkers to reproduce the verdict. Receipts attesting superseded builds credit no layer and are omitted from this rendering (the count of omissions, if any, is noted below).

| receipt          | minted               | layers             | status  |
|------------------|----------------------|--------------------|---------|
| 8130a7a7a679cef4 | 2026-08-04T01:16:06Z | build+decorrelated | current |
| 9eb3706354082144 | 2026-08-04T02:23:12Z | build+decorrelated | current |

5 further receipt(s) in the store attest superseded builds of this module and are omitted from this rendering.

### gate-layer coverage of the bound build:

build (lake build (elaboration)) current  
 replay (leanchecker (official kernel replay)) stale only  
 hardened (safe\_verify (hardened screen)) stale only  
 decorrelated (lean4export + nanoda (decorrelated kernel)) current

**comparator: none** no fixture in the three-implementation comparator harness (compiled / kernel-interpreted / reference-interpreted) exercises this rule.

## HOL4 statement

### NO HOL STATEMENT YET

Absent: the HOL4 development's object is the base-kernel checker cone, and the satisfaction-judgment stratum this rule concludes in has no HOL twin — no judgment-stratum definition exists in the ported scripts (verified against the port's definition inventory). The disjointness rows this rule consumes ARE covered by the ported checker; the three-line judgment-stratum soundness lemma is Lean-only today.

## HOL verifier receipts

### NONE

no HOL verification receipt exists for this rule.

## Proof

Genre: core rule (tier 1) — an ordinary mathematical proof at Putnam-exam-solution detail. Every hypothesis of the rule is used below and remarked on; the formal-anchor table maps each step to the Lean declaration that carries it. This rule concludes a judgment one stratum above the sequent calculus: premises typed  $\vdash$  are ordinary sequents the base kernel replays, and the rule's own soundness lives at the judgment stratum, over a dynamical model. Uniquely among the Morse-family rules in this book, its mechanization is *unconditional*: the cited theorems are proved outright, with no interface hypotheses.

**Setting and claim.** Fix a *forward semiflow*  $\varphi$  on a state space  $X$ : a map  $\Phi : \mathbb{R}_{\geq 0} \times X \rightarrow X$ , written  $\Phi_t$ , with  $\Phi_0 = \text{id}$  and  $\Phi_{s+t} = \Phi_s \circ \Phi_t$  (the abstract shadow of the model class: a deterministic polynomial-drift flow on its chart domains; the two semiflow laws are model-frame data — the proofs below consume only the rule premises (a)–(c)). Regions denote subsets of  $X$ . Two judgment forms participate:

(*invariance scope*)  $\text{QInvScope}(S, X_0)$  asserts the conjunction:  $S$  is forward-invariant ( $x \in S \Rightarrow \Phi_t x \in S$  for all  $t \geq 0$ ) and  $X_0 \subseteq S$ .

(*safety*) the region judgment  $\mathcal{M}, x_0 \in X_0 \vdash \text{SProbGE}(1, \text{PAlways}(\text{SNot } \beta))$  asserts, in the deterministic reading, that every point of  $X_0$  avoids  $B := \llbracket \beta \rrbracket$  at every forward time:  $\forall x \in X_0, \forall t \geq 0, \Phi_t x \notin B$ . The probability-one former  $\text{SProbGE}(1, \cdot)$  is the degenerate probabilistic costume of this universal statement — no measure, no stochastic machinery, and no supermartingale certificate participates anywhere in this section (the model-class fence: deterministic flows only).

The rule's premises: the cited invariance judgment (an internal edge — the claim is consumed, not its derivation), and one disjointness fact  $S \cap \llbracket \beta_j \rrbracket = \emptyset$  per avoid region, discharged by per-box sign rows of the base calculus (or by cell bookkeeping the checker recomputes, when  $\beta_j$  is aligned to the certificate's grid).

**Theorem R74.1** (soundness of QBASIN). *Let  $S, X_0, B \subseteq X$  with (a)  $S$  forward-invariant, (b)  $X_0 \subseteq S$  (jointly: the cited  $\text{QInvScope}(S, X_0)$  judgment), and (c)  $S \cap B = \emptyset$ . Then every  $x \in X_0$  satisfies  $\Phi_t x \notin B$  for all  $t \geq 0$ .*

*Proof.* Three sentences. By (b),  $x \in S$ ; by (a),  $\Phi_t x \in S$  for every  $t$ . Were  $\Phi_t x \in B$ , it would lie in  $S \cap B$ , which (c) declares empty. Hence  $\Phi_t x \notin B$ .  $\square$

**Proposition R74.2** (the batch form). *Let  $\{B_j\}_{j \in J}$  be any family of avoid regions with, for each  $j$ , the single fact  $S \cap B_j = \emptyset$ . Under (a) and (b) of Theorem R74.1, every  $x \in X_0$  avoids  $\bigcup_j B_j$  at every forward time — equivalently, each  $B_j$  separately, and all of them jointly.*

*Proof.* A point of the union lies in some  $B_j$ ; apply Theorem R74.1 to that  $j$ . Nothing about  $J$  is used — the index family may be infinite, though a certificate of course carries finitely many rows.  $\square$

**Remark R74.3** (each hypothesis is load-bearing). Drop (a), keeping (b) and (c): on  $X = \mathbb{R}$  with the unit-speed drift  $\Phi_t x = x + t$ , take  $S = X_0 = [0, 1]$  and  $B = [2, 3]$ . Then  $X_0 \subseteq S$  and  $S \cap B = \emptyset$ , yet the trajectory from  $x = 0$  enters  $B$  at  $t = 2$  — invariance is the entire dynamical content of the rule, and it arrives wholesale through the cited judgment. Drop (b): a point  $x \in X_0 \setminus S$  may sit in  $B$  already, violating the conclusion at  $t = 0$  — concretely, the identity flow with  $S = \{0\}$  and  $X_0 = B = \{1\}$ : (a) and (c) hold, and the start state is the violation. Drop (c): a point of  $S \cap B$  reachable from  $X_0$  (at worst a point of  $X_0 \cap B$  itself, again at  $t = 0$ ) violates it — concretely, the identity flow with  $X_0 = S = B = \{0\}$ : (a) and (b) hold, and the start state sits in the avoid set. The two set-theoretic hypotheses fail at time zero when dropped; the dynamical one fails at positive time — which is why (a) is a judgment with its own producing rules while (b) and (c) are single containment/disjointness rows.

**Remark R74.4** (the premise is the invariance judgment, not the Morse judgment). A natural mis-design would take the global Morse judgment as the premise: it is the stronger-looking claim. But  $\text{Morse}(G, \rho)$  alone implies no particular invariant enclosure of  $X_0$  — an orbit from  $X_0$  may transit  $\llbracket \beta \rrbracket$  en route to its Morse set (concretely:  $\dot{x} = 3 - x$  on  $\mathbb{R}$ , Morse structure the attractor  $\{3\}$ ,  $X_0 = \{0\}$ ,  $B = (1, 2)$  — the orbit crosses  $B$  on its way to the attractor), so recurrence structure without an enclosure proves no safety at all. The sound premise is the certificate-level invariance fact, and the Morse machinery contributes through the *factory* instead: every lattice member of the family object (and every down-closed cell-set, via  $\text{QLATTICEINV}$ ) yields a  $\text{QInvScope}$  judgment whose facet rows already exist in the family object. This rule then mints one safety atom per avoid region at the price of that region's own disjointness rows and *nothing else* — the invariance side is cited, never re-certified, so no invariance or facet row is ever added however many avoid regions arrive — which is the row-count payoff the batch form (Proposition R74.2) states as mathematics.

**Remark R74.5** (what the checker recomputes). At this rule the checker verifies: that the cited judgment's region and init fields equal the rule's own scope data (the conclusion tie), and the disjointness rows — per-box, per-atom sign sequents of the base calculus, or grid bookkeeping when  $\beta_j$  is cell-aligned. Nothing else: soundness is pure logic over the judgment's semantic content, which is why the mechanized statement is three lines and hypothesis-free. Basin-minted and battery-minted safety atoms are *type-identical* conclusions, deliberately: downstream citations consume the judgment and may not key on its producer.

**Remark R74.6** (relation to the literature). Safety-by-invariance is the classical frame of set-invariance control — Nagumo's subtangentiality theorem [187] is the ancestral invariance certificate, and Blanchini's survey [23] the modern map of the field — and of barrier certificates [201], which in their usual packaging synthesize one function per specification, coupling the invariance

argument to the safety argument. The rule’s point is the *decoupling*: invariance is certified once, as a judgment (by strictly inward facet rows, at QBLOCKINV), and each safety claim is thereafter a citation plus disjointness rows. The batch corollary is the certificate-side face of the elementary observation that one invariant set separates its contents from every disjoint avoid set at once.

| proof step                                               | formal anchor                                                                             |

## 15.9 Existence Certificates

### Rule 75. QZEROBYMIRANDA (core rule)

#### The rule (Steele metanotation)

as realized in the mechanized development; source row: QTSL-rules.toml — *QZeroByMiranda*. The metanotation statement is typeset by hand for notational quality; this rule cites no Lean statements yet (the absence is stated loudly below). The rule *roster* is machine-checked (every mechanized rule tag round-trips to exactly one catalogue row); the statement *text* is editorial.

$$\frac{b : \text{QMirandaBattery} \quad \text{qtsl\_miranda\_battery}(b, C, g, \Pi)}{\models \text{QZeroExists}(g, C)}$$

QZEROBYMIRANDA is Miranda's theorem as a certificate:  $2m$  face rows over an equidimensional polynomial view, each row a sign sequent claiming the signed component restricted to one face of the cell nonpositive on the lower face and nonnegative on the upper — and the theorem concludes a zero of the vector field inside the cell. Existence only: nothing in this family can conclude uniqueness, count, or non-existence. Face geometry is derived from each row's indices, never stored — a producer-supplied face would be a trusted row — and the face-restriction recompute (exact-rational substitution) is the walk's derived-sequent authority.

**notes** The battery walk checks completeness (each (axis, face) exactly once), per-axis component agreement, component bijectivity, and index ranges as decided-false violations; non-box atoms, non-canonical or over-wide polynomials, list ambiguity, and budget overruns refuse with no verdict. Entered at the roster census (baked, never catalogued); no Lean statement binds it yet.

#### Theory rows (geolog)

The rule's certificate content as it is declared in the geolog theory the checker loads — payload schema, side-condition demands, and axiom rows, quoted from the theory source at every build of this catalogue (a stale quotation cannot exist). Axiom modes: chase = the engine derives; report = a violation is a loud judgment; refuse = a violation gates admission. Side-condition relations are discharged by bounded evaluation at the engine's ground seam, never by derivation.

#### Lean statement

**not yet mechanized** this rule cites no Lean statements: nothing on this page is hash-bound for it, and its dashboard row shows the same absence across the statement, receipt, and correspondence columns.

#### HOL4 statement

##### NO HOL STATEMENT YET

No HOL development of the extension theory exists.

#### HOL verifier receipts

**NONE**

no HOL verification receipt exists for this rule.

## Proof

Genre: core rule (tier 1), existence group. This section states the rule’s soundness obligation exactly, per the catalogue’s completeness-over-polish charter (a rule that can only be named-and-gapped is still a row); the discharge is open debt on the mechanization column, and the schema quoted in the entry is the baked ground truth.

**Soundness obligation.** Miranda’s theorem, certified: if each signed component of the equidimensional polynomial view is nonpositive on its lower face and nonnegative on its upper face of the cell (the  $2m$  face rows, with face geometry derived from row indices and each restriction recomputed by exact-rational substitution), then the view has a zero in the cell — for every parameter point of the parameter cell. Existence only; uniqueness, count, and non-existence are outside the family by design.

*Remark* R75.1 (status). No Lean statement binds this node. Miranda’s theorem (Poincaré–Miranda) is classical; the mechanization route would state it over the boxed cell with the walk’s derived face restrictions as hypotheses.

## Rule 76. QEQUILIBRIUMFROMINWARD (admissible rule)

### The rule (Steele metanotation)

as realized in the mechanized development; source row: QTSL-rules.toml — *QEquilibriumFromInward*. The metanotation statement is typeset by hand for notational quality; this rule cites no Lean statements yet (the absence is stated loudly below). The rule *roster* is machine-checked (every mechanized rule tag round-trips to exactly one catalogue row); the statement *text* is editorial.

$$\frac{\text{inv} : \text{QBlockInv} \text{ (strictly-inward facets, box block)}}{\models \text{QEquilibriumExists}(f, C)}$$

QEQUILIBRIUMFROMINWARD is a derived rule: a strictly-inward facet battery on a box block — every facet's sign sequent points the field inward — is already the existence battery for the negated field with identity pairing, so an equilibrium inside the block follows by citation, with zero new oracle demand. The premises are the block-invariant evidence rows themselves; the unpacking instantiates the zero-existence obligation.

**notes** For fixed points the battery's subject is the map minus the identity; the elaboration recompute tying the two is a named deferral at the ground seam. Entered at the roster census (baked, never catalogued); no Lean statement binds it yet.

### Theory rows (geolog)

The rule's certificate content as it is declared in the geolog theory the checker loads — payload schema, side-condition demands, and axiom rows, quoted from the theory source at every build of this catalogue (a stale quotation cannot exist). Axiom modes: chase = the engine derives; report = a violation is a loud judgment; refuse = a violation gates admission. Side-condition relations are discharged by bounded evaluation at the engine's ground seam, never by derivation.

theory Qtsl . QEquilibriumFromInward

quoted from the theory source at render

| QEquilibriumFromInward : Set;

theory Qtsl . QEquilibriumFromInward/\*

quoted from the theory source at render

| QEquilibriumFromInward/proof : QEquilibriumFromInward -> QProof;  
| QEquilibriumFromInward/inv : QEquilibriumFromInward -> QBlockInv;

### Lean statement

**not yet mechanized** this rule cites no Lean statements: nothing on this page is hash-bound for it, and its dashboard row shows the same absence across the statement, receipt, and correspondence columns.

### HOL4 statement

**NO HOL STATEMENT YET**

No HOL development of the extension theory exists.

### HOL verifier receipts

**NONE**

no HOL verification receipt exists for this rule.

### Proof

Genre: admissible rule (tier 2), existence group. This section states the rule's soundness obligation exactly, per the catalogue's completeness-over-polish charter (a rule that can only be named-and-gapped is still a row); the discharge is open debt on the mechanization column, and the schema quoted in the entry is the baked ground truth.

**Soundness obligation.** A strictly-inward facet battery on a box block is the existence battery for the negated field with identity pairing: inwardness on every facet gives exactly the sign pattern Miranda's theorem demands for  $-f$ , so the unpacking cites the block-invariant evidence rows and instantiates the zero-existence obligation — premises by citation, zero new oracle demand. Soundness is therefore inherited from the zero-existence rule's obligation.

*Remark R76.1 (status).* No Lean statement binds this node; its obligation factors entirely through the zero-existence rule's. For fixed points the battery's subject is the map minus the identity, and the elaboration recompute tying the two is a named deferral at the ground seam.

## Rule 77. QCOVERBYMIRANDA (core rule)

### The rule (Steele metanotation)

as realized in the mechanized development; source row: QTSL-rules.toml — *QCoverByMiranda*. The metanotation statement is typeset by hand for notational quality; this rule cites no Lean statements yet (the absence is stated loudly below). The rule *roster* is machine-checked (every mechanized rule tag round-trips to exactly one catalogue row); the statement *text* is editorial.

$$\frac{b : \text{QMirandaBattery} \quad \text{qtsl\_miranda\_battery}(b, W, \sigma - \text{id}_Z, Z)}{\models Z \subseteq \sigma(W)}$$

QCOVERBYMIRANDA is the chart-image discharge at per-(patch cell, target cell) granularity: the battery's subject is chart minus target in joint variables, with the target cell as parameters — a certified zero of  $\sigma(w) - z$  in the patch cell for every  $z$  in the target cell is exactly the containment of the target cell in the chart image. Union to a region cover rides the existing cover machinery; a cover is never inferred from an image enclosure — enclosures bound images from outside, and only the zero-existence argument bounds them from inside.

notes Entered at the roster census (baked, never catalogued); no Lean statement binds it yet. The battery walk is shared with the zero-existence rule.

### Theory rows (geolog)

The rule's certificate content as it is declared in the geolog theory the checker loads — payload schema, side-condition demands, and axiom rows, quoted from the theory source at every build of this catalogue (a stale quotation cannot exist). Axiom modes: chase = the engine derives; report = a violation is a loud judgment; refuse = a violation gates admission. Side-condition relations are discharged by bounded evaluation at the engine's ground seam, never by derivation.

| QCoverByMiranda/battery : QCoverByMiranda -> QMirandaBattery;

### Lean statement

**not yet mechanized** this rule cites no Lean statements: nothing on this page is hash-bound for it, and its dashboard row shows the same absence across the statement, receipt, and correspondence columns.

### HOL4 statement

#### NO HOL STATEMENT YET

No HOL development of the extension theory exists.

### HOL verifier receipts

#### NONE

no HOL verification receipt exists for this rule.

### Proof

Genre: core rule (tier 1), existence group. This section states the rule's soundness obligation exactly, per the catalogue's completeness-over-polish charter (a rule that can only be named-and-gapped is still a row); the discharge is open debt on the mechanization column, and the schema quoted in the entry is the baked ground truth.

**Soundness obligation.** For each target point  $z$  of the target cell, the battery (subject: chart minus target in joint variables, parameters the target cell) certifies a zero of  $\sigma(w) - z$  in the patch cell — i.e. a preimage of  $z$  under the chart — so the target cell is contained in the chart image. Union to a region cover rides the existing cover machinery; a cover is never inferred from an image enclosure.

*Remark R77.1* (status). No Lean statement binds this node; the obligation factors through the zero-existence rule's, applied parametrically in the target point.

## 15.10 Composition and Aggregation

### Rule 78. QWIRECOMPOSE (core rule)

#### The rule (Steele metanotation)

as realized in the mechanized development; source row: QTSL-rules.toml — *QWireCompose*. The metanotation statement is typeset by hand for notational quality; its mechanized ground truth is the Lean statement below, extracted from the sources at every build of this book and hash-bound. The rule *roster* is machine-checked (every mechanized rule tag round-trips to exactly one catalogue row); the statement *text* is editorial, checked by eye against the extracted Lean beside it.

$\{\Sigma_i \models (I_i, \alpha_i, \gamma_i[\cdot, \kappa_i])\}_{i=1}^n$      $\text{QWireCert}(w, (\text{spec}_i)_i \Rightarrow \text{spec}_{\text{out}})$

$\text{rank} : \{1, \dots, n\} \rightarrow \mathbb{N}; \quad \{\text{rank}_i < \text{rank}_j\}_{(i \rightarrow j) \in w}$     (the causality certificate: one rank per component)

W0: the composite martingale problem admits a càdlàg strong-Markov solution, unique in law, from every initial state (stochastic mechanism)

W1: transition data factor through per-place colour multisets (SDCPN mechanisms; typing-)

W2: the within-instant immediate-jump relation is well-founded, of uniformity

W3: simultaneous enablings carry a declared serialization or a certified reset commutation (a.s.)

$\kappa_{\text{out}} := \bigoplus_{\text{legs}} \kappa_{\text{leg}}, \quad \kappa_a \oplus \kappa_b := \kappa_a + \kappa_b$  (slack addition along lens composition; check)

$\text{SysWire}(w, [\Sigma_1, \dots, \Sigma_n]) \models \text{spec}_{\text{out}}$

satisfaction of an interface-bearing spec is plain *QSat* — behaviours whose inputs conform to the assumption deliver the guarantee; closed  $\mathcal{M} \models s$  is the empty-interface instance (defined once at the judgment-kinds home; the former subscripted display  $\models_1$  and the *QSatI* sort are both dissolved). The first two premises are derivation edges (judgment-kind premises); the well-posedness families enter as proof leaves on the node's own well-posedness list, each owed only by the mechanism profiles that name it — W0 by stochastic profiles, W1 by SDCPN profiles, W2/W3 the syntactic class (their four-way recompute relation is not yet enacted; the leaves enter as posted proof rows) — and the causality ranks ride the node as one natural per component. The causality certificate and the slack composite are recomputed by the checker. Tier split derived from mechanism field-family population, never a stored tag: **admissible** where every mechanism derives ODE/discrete — the composite certificate  $\sum_i \lambda_i V_i$  is syntactically constructible and the node unpacks through the sequent-layer transport (PROMISE/SYZGY) — **core** where any mechanism is stochastic (SDE/GSHS): the warrant is the per-profile semantic theorems. This display is the acyclic  $n$ -ary form (the causality certificate makes a directed cycle unrepresentable); feedback rides the binary small-gain cells, sum-form and gauge-form.

QWIRECOMPOSE is the satisfaction-judgment stratum's composition rule — assume-guarantee transport over a structured system presentation. From interface-indexed satisfaction of each component (*QSatI*( $\Sigma_i, \text{spec}_i$ ): every behaviour of  $\Sigma_i$  whose inputs satisfy the assumption  $\alpha_i$  delivers the guarantee  $\gamma_i$ , with quantitative slack where declared) and a wiring certificate (the lens square transporting delivered guarantees into downstream assumptions, with slack  $\kappa \in \mathcal{K}_{\infty}^0$ ), it concludes satisfaction of the wired composite at the output spec. A producer uses it to certify a system of interacting components — each certified once, against its own datasheet — without ever building the monolithic certificate.

The soundness warrant factors, and the factorization organizes everything on this page:  $\text{sound} = (\text{transport arithmetic}) \circ (\text{semantic reading})$ . The transport half is profile-generic exact polynomial arithmetic — the  $(1, \lambda, 1, 1)$  cancellation of cross-supplies, the sequent-layer machinery of PROMISE and SYZGY — and consumes only linearity of the obligation operator over the wiring. The semantic half is per-profile, and it is where this entry's conditional check lives. What the cited theorems prove, per profile and shape: for general stochastic hybrid systems (GSHS), *series* composition (the conditioning tower, qualitative and product-bound forms, plus the certified pipeline through the maximal-inequality kernel), *parallel* composition (the weighted-sum supermartingale — the semantic face of the syzygy weights), and *feedback in sum-form* (the cancellation run under conditional expectation along the joint jump skeleton, with non-expansive boundary rows) are proven; the  $n$ -ary *acyclic* assembly is proven at any  $n$  by strong induction on the causality certificate, with union-bound slack composition; and the per-profile tier split is itself a proven, derived function of the presentation. *Feedback in gauge-form* (jumps that expand the certificate, repaid by flow decay) is partial: its reduction theorem and the max-form piecewise-deterministic instance are machine-checked end-to-end, while the finite-index price of the diffusion term and the admissible-window pinch remain open — with the diffusion cell's parking reason retired: within-segment decay for gauged certificates is now available at the martingale-problem profile, so the open part is the accounting, not the stochastic calculus. The deterministic-ODE row is at statement level; the discrete-kernel row's assembly is proven — B1  $n$ -ary acyclic, B2 parallel, and B3 sum-form small-gain, end-to-end over the trajectory kernel — while the sampled-data row remains stated, not yet assembled. The discrete row carries a substrate asymmetry worth stating with the grid: it consumes *no* interface hypothesis fields (contrast the GSHS cells' D0–D4 data — Dynkin, début sampling, skeleton adaptedness), because its execution semantics is mathlib's own `Kernel.traj`. The commentary states this grid plainly because the dashboard's conditional mark warrants exactly the proven cells, never the whole catalogued rule.

Two fences are part of the statement, not omissions. Undirected stochastic wire sharing (common noise) is out of scope: stochastic components sharing a wire need exactly one determining side, and the proven parallel cell covers directed coupling and disjoint tensor only. And the  $n$ -ary theorems are acyclic by construction — the presentation's causality certificate makes a directed cycle

unrepresentable — so feedback rides the binary small-gain cells, where the coupling of jump times between the two components is handled by the joint-skeleton argument.

What a checker recomputes, the rule's row sorts now baked: the causality certificate (a rank function strictly increasing along wires), the slack composite (lens composition plus slack addition, with the class membership rows discharged by `QWIRECERTDISCHARGE`), and the well-posedness row families for the stochastic profiles. The component satisfactions and the wiring squares are cited judgments and inherited sequent leaves — the rule adds no kernel arithmetic of its own.

**notes** The tier split is derived from mechanism field-family population, never stored as a tag: admissible where every mechanism in the presentation derives the ODE or discrete profile (the composite certificate  $\sum_i \lambda_i V_i$  is syntactically constructible and the node unpacks through the sequent-layer transport), core where any mechanism is stochastic (no unpacking exists; the semantic theorems are the warrant). One rule node either way. The judgment sorts the rule concludes into are baked in the extension theory; the checker chain that would consume them is not yet ported — the rule is proven ahead of being wireable, and the dashboard row shows exactly that state.

## Lean statement

/--! ## The admissible face's constructibility, pointwise

The composite certificate for the admissible tier is the weighted sum
 $\sum i, \lambda i \cdot V i$ ; its composite obligation row follows *pointwise* from the
component dissipation rows ( $e i \leq 0$  on the operating region) and the wiring
```

```

identification rows (`g k = 0` there), at nonnegative certificate weights and
free-sign wiring multipliers. This is the pointwise shadow of the landed
sequent-layer theorem (`sound_syzygy`, main package – the (T) layer of the
inventory §0 factorization); it lives here so that the tier definition's
"syntactically constructible" clause is a statement, not prose. -/
theorem admissible_construts {ι κIdx X : Type*} [Fintype ι] [Fintype κIdx]
  (R : Set X) (lam : ι → ℝ) (e : ι → X → ℝ) (nu : κIdx → ℝ) (g : κIdx → X → ℝ)
  (hlam : ∀ i, 0 ≤ lam i)
  (he : ∀ i, ∀ x ∈ R, e i x ≤ 0)
  (hg : ∀ k, ∀ x ∈ R, g k x = 0) :
  ∀ x ∈ R, (∑ i, lam i * e i x) + (∑ k, nu k * g k x) ≤ 0

```

BernsteinLogicAux.QtslCompose.AGCompose.**sat\_of\_conform**

statement bound

```

/-- **Conformance propagation** (pointwise core). If the wiring squares
transport external conformance + upstream deliveries into each component's
conformance, and each component delivers on conforming inputs (at this `ω`),
then every component delivers. Strong induction on the causality rank – the
presentation's causality certificate is exactly what makes this well-founded. -/
theorem sat_of_conform
  (hw : ∀ j, conformExt n (⋂ i ∈ S.upstream j, sat i) ⊆ conform j)
  {ω : Ω} (h : ∀ j, ω ∈ conform j → ω ∈ sat j)
  (hext : ω ∈ conformExt) : ∀ j, ω ∈ sat j

```

BernsteinLogicAux.QtslCompose.AGCompose.**qualitative**

statement bound

```

/-- **QWireCompose, qualitative form** (a.e.; the n-ary generalization of
`AGCompose.Series.qualitative`): component QSatI's as a.e. implications +
wiring squares yield the composite a.e. delivery of every guarantee, hence of
any output spec read from them (`hout`). -/
theorem qualitative [MeasurableSpace Ω] {μ : Measure Ω}
  (hw : ∀ j, conformExt n (⋂ i ∈ S.upstream j, sat i) ⊆ conform j)
  (h : ∀ j, ∀m ω ∂μ, ω ∈ conform j → ω ∈ sat j)
  {satOut : Set Ω} (hout : conformExt n (⋂ j, sat j) ⊆ satOut) :
  ∀m ω ∂μ, ω ∈ conformExt → ω ∈ satOut

```

  (hε : ∀ j, μ (conform j n (sat j)c) ≤ ε j) :
  μ (conformExt n satOutc) ≤ ∑ j, ε j

```

**The B-row (discrete-kernel) assembly.** The row the commentary's grid records as proven: B1  $n$ -ary acyclic union-bound composition through the first-failure device, B2 parallel weighted-sum on the product kernel, B3 sum-form small-gain cancellation — machine-checked end-to-end over Kernel.traj through the battery substrate, with no semantic hypothesis fields (the profile identification enters as the choice of substrate, which is the conditional mark's honest residue for this row).

BernsteinLogicAux.QtslCompose.AGComposeDiscrete . **firstFail**

statement bound

```
/-- The event that component `j` is a first violator: at some time the path
is in `j`'s violation set, no component's violation set having been visited
before. Distinct components' first-failure events may overlap (simultaneous
first violations); the union bound is indifferent. -/
def firstFail (bad : Fin m → Set S) (j : Fin m) : Set (ℕ → S)
```

BernsteinLogicAux.QtslCompose.AGComposeDiscrete . **reach\_subset\_iUnion\_firstFail**

statement bound

```
/-- The first-failure decomposition (the discrete-profile face of K4's event
decomposition; kin of the event-stratum `AGCompose.fail_subset`, with
time-minimality replacing rank-minimality): a path that ever visits any
violation set has a first violation, and that violation belongs to some
component. Pure path-set algebra. -/
theorem reach_subset_iUnion_firstFail (bad : Fin m → Set S) :
  {ω : ℕ → S | ∃ n, ω n ∈ ⋃ i, bad i} ⊆ ⋃ j, firstFail bad j
```

BernsteinLogicAux.QtslCompose.AGComposeDiscrete . **measure\_firstFail\_le**

statement bound

```
/-- The stopped-process device (inventory §3.B1), isolated: stopping the
composite chain at the first violation by any component, component `j`'s
certificate — with drift live off the joint violation set and barrier only
on `j`'s own violation set — bounds the probability that `j` fails first
by its initial value. K1 (Supermartingale.ville_ineq) at barrier `1`;
contrast `Battery.measure_reach_le`, whose barrier must cover the whole stop
set and which therefore cannot see a multi-component decomposition. -/
theorem measure_firstFail_le {bad : Fin m → Set S} {V : S → ℝ} {C : ℝ} {j : Fin m}
  (hA : MeasurableSet (⋃ i, bad i)) (hV : Measurable V)
  (hV0 : ∀ y, 0 ≤ V y) (hVC : ∀ y, V y ≤ C)
  (hbar : ∀ y ∈ bad j, 1 ≤ V y)

    ≤ ENNReal.ofReal (V1 x + lam * V2 x)

```

## Correspondence (Steele display ↔ Lean)

**a bound Lean statement CHANGED since certification — re-review and re-certify** The dictionary below is a reviewer-certified statement of how the mechanized statements above interpret the displayed rule: display metavariable  $\mapsto$  Lean binder, each display hypothesis  $\mapsto$  the premise or side condition carrying it, the display conclusion  $\mapsto$  the goal — with any deliberate difference in width between display and mechanization named outright. Certification is recorded as a hash triple over (the displayed cell, the extracted statement texts, this dictionary's own text); if any of the three changes, this block turns amber until a reviewer re-certifies. The correspondence claim itself remains editorial — reviewer-grade, not machine-checked; its machine-checked successor types each soundness statement against the rule as a structured object, and supersedes this block per rule as it lands.

The display is one  $n$ -ary rule; the bound set is a *grid*, and the dictionary's first duty is to say which display constituent lands in which theorem. All statements live over the compiled behaviour space ( $\Omega$ , the composite execution law's carrier), reached from the presentation through bridge hypotheses — the events conform  $j / \text{sat } j$  (component  $j$ 's input-conformance and guarantee-delivery, interpreted over composite behaviours: the I-bridge of the kernel-semantics interface) — so the certified statements quantify over exactly the Systems whose compilation discharges those bridges.

- the E1 premises  $\Sigma_i \models (\dots)$  (the QSatI judgments)  $\mapsto$ ,  $n$ -ary face:  $h : \forall j, \forall^\# \omega \partial \mu, \omega \in \text{conform } j \rightarrow \omega \in \text{sat } j$  (qualitative) and quantitatively  $h\epsilon : \mu (\text{conform } j \cap (\text{sat } j)^c) \leq \epsilon_j$  (fail\_bound) — per-component satisfaction as a.e. implication / failure-measure bound.
- the QWireCert premise  $\mapsto$   $hw : \forall j, \text{conformExt } n (\cap i \in S.\text{upstream } j, \text{sat } i) \subseteq \text{conform } j$ : the wiring squares with the  $\kappa$ -slack *folded into the predicates*. Consequence, stated plainly: the displayed  $\kappa_{\text{out}}$  recompute row has no counterpart in the  $n$ -ary bound statements — quantitative slack composition appears instead as the union-bound  $\sum_j \epsilon_j$  (fail\_bound\_out, the inventory's  $\sum_i (1 - p_i)$  display at any  $n$ ).

- the causality certificate  $\mapsto \text{System.rank} + \text{System.causality as data}$  (the structure is bound by display): rank strictly increasing along wires is a field, the induction of `sat_of_conform` runs on it, and a directed cycle is unrepresentable — the Lean face of “recomputed.”
- W0–W3 well-posedness rows  $\mapsto$  nothing bound — schema-stratum families, honestly absent.
- the conclusion  $\text{SysWire}(w, \vec{\Sigma}) \models \text{spec}_{\text{out}} \mapsto$  qualitative's goal (a.e. delivery of `satOut` on conforming inputs) and `fail_bound_out`'s (failure measure at the output spec), with hout the output reading of the delivered guarantees; `fail_subset` is the pure set-algebra localization engine (a composite failure localizes at a rank-minimal failing component, conforming there).
- the tier split (the display's admissible/core tier split, stated in the flavor text)  $\mapsto \text{System.qagTier}$ , a *derived function of the presentation* with both unfoldings proven (`qagTier_admissible_iff`: every chart ODE or discrete; `qagTier_core_iff`: some chart stochastic), and `admissible_constructs` making “syntactically constructible” a statement: composite row of  $\sum_i \lambda_i V_i$  from component dissipation rows + wiring identification rows, pointwise, at nonnegative certificate weights and free-sign wiring multipliers — the pointwise shadow of the main package's `sound_syzygy` (witness prose, package boundary).
- the binary GSHS cells, premise shapes as bound: `Series.certified` consumes two supermartingale certificates (Supermartingale  $Y_1 \otimes \mu$ , nonneg, positive barriers, floor-row transport `hbar_1`, violation-witness inclusions `hwit_1`) + one wiring square `conform_1 n sat_1  $\subseteq$  conform_2`, concluding the composite failure bound with certificate-valued  $\varepsilon$ 's (initial mass over barrier, per component); `Parallel.certified / certified_pair` conclude the avoid bound for the weighted-sum certificate (the semantic face of the syzygy weights); `FeedbackSum.supermartingale / avoid_bound` operate on the bundled `SumFormFeedback` structure — and its binder rows carry a width find: `soundness` consumes only  $0 \leq \text{lambda}$ ,  $0 \leq \text{theta}$ ; the rule-level ranges  $\lambda > 0$ ,  $\theta \in (0, 1)$  are well-formedness, never hypotheses — with the  $(1, \lambda, 1, 1)$  cancellation entering as the two integrated a.e. membership rows `mem_1/mem_2`; `sound_GSHS_safety_barrier` is the  $\kappa = 0$  max-form PDMP instance at a general positive floor `m`, consuming measurability, kernel instances, Dynkin/non-expansion data, and a global bound `C` on the certificate.
- the B-row (discrete-kernel) assembly (`AGComposeDiscrete`; end-to-end over `Kernel.traj` through the battery substrate, with *no* D-layer hypothesis fields — the semantic hypotheses of the GSHS cells above have no counterpart here because the discrete substrate is in Lean): the E1 premises  $\mapsto$  per-component bounded certificates  $V_j$  with datasheet drift on `conf j` and barrier  $1 \leq V_j$  on `bad j` (state-level); the `QWireCert` premise  $\mapsto \text{hw} : \bigcap i \in \text{upstream } j, (\text{bad } i)^c \subseteq \text{conf } j$  — the square pre-folded at the state stratum, while rank and causality stay event-stratum: time-minimality (the first-failure device, `firstFail / measure_firstFail_le`, the K1-consumption primitive the multi-component setting needs) replaces the rank induction, so `System.rank/causality` are honestly unused in `fail_bound_wired`; the conclusion  $\mapsto$  the failure-measure bound  $\sum_j \text{ofReal}(V_j x)$ , the  $\varepsilon$ 's of the event-stratum `fail_bound established` rather than assumed. K2 (optional stopping) is consumed transitively — it is bridge step 1 inside `ville_ineq` — and no direct optional-stopping consumption is needed for avoid-shaped conclusions. B2/B3 transpose the binary GSHS cells to the kernel level: `drift_parallelComp / avoid_parallelComp` (the weighted-sum row on  $K_1 \parallel K_2$ , the discrete face of the parallel cell) and `smallGain_drift / avoid_smallGain` (the  $(1, \lambda, 1, 1)$  cancellation, consuming only  $0 \leq \text{lam}$  and  $0 \leq \text{theta}$  — the sum-form cell's width find reproduced at this stratum).

Width note: the conditional mark's content is the grid-vs-rule gap the commentary already states (the deterministic-ODE row at statement level, the sampled-data row stated but not yet assembled, feedback in gauge-form partial; the discrete-kernel row's assembly is discharged, so the gap is one row lighter) — the dictionary adds that within the *proven* cells the mappings above are exact, that the  $n$ -ary statements are acyclic by type (not by side condition), and that no bound statement consumes the  $\mathcal{K}_\infty^0$  structure of  $\kappa$  itself (that lives in `QWIRECERTDISCHARGE`'s bound set; here slack is pre-folded or union-bounded).

## Lean verifier receipts

module `BernsteinLogicAux.AGCompose.GshsSeries`; bound build `ff5cb858ef68...` (bound from receipt `911818331ed966fc`, 2026-07-20T01:42:13Z). A receipt records that named checking layers accepted a build: (module, compiled-artifact SHA-256, environment SHA-256, checker layers), minted when the checking gate ran; the store receipts attesting the bound build are listed with the layers each run credited. Nothing here asks the reader to trust the store: every layer is an independently runnable program over the quoted sources — rebuild the module and re-run the checkers to reproduce the verdict. Receipts attesting superseded builds credit no layer and are omitted from this rendering (the count of omissions, if any, is noted below).

| receipt          | minted               | layers                             | status  |

gate-layer coverage of the bound build:

- build (lake build (elaboration)) current
- replay (leanchecker (official kernel replay)) current
- hardened (safe\_verify (hardened screen)) current
- decorrelated (lean4export + nanoda (decorrelated kernel)) current

comparator: none no fixture in the three-implementation comparator harness (compiled / kernel-interpreted / reference-interpreted) exercises this rule.

HOL4 statement

NO HOL STATEMENT YET

The satisfaction-judgment extension postdates the HOL4 port entirely: the ported cone is the base calculus's first-order check-function surface (theory bern\_catalogue, stopping before even the base proof-object layer), and no extension-theory definition exists anywhere in the HOL development. A HOL statement of this rule presupposes a HOL port of the satisfaction stratum, which is its own campaign; until then this box is the honest state of the edifice.

HOL verifier receipts

NONE

no HOL verification receipt exists for this rule.

## Proof

Genre: core rule (tier 1), with a per-profile tier split derived from the presentation. The coverage is deliberately conditional: this section proves the cells the mechanization proves, names the bridge hypotheses under which they apply, and states what remains open — never claiming past the mechanized grid.

**Setting and claim.** A system is a structured presentation: finitely many *mechanisms* (primitive dynamics declarations — drift, diffusion, jump, and guard–reset field families over typed wires), plus *wirings* (variable identifications) carrying a *causality certificate* — a rank function strictly increasing along wires, so a directed cycle is unrepresentable in the assembled structure. Each mechanism’s *doctrine profile* is derived from which field families are populated: drift only = ODE; +diffusion = SDE; +real-time jumps = general stochastic hybrid (GSHS); counter-time jumps only = discrete kernel. An interface-indexed satisfaction judgment  $\text{QSatl}(\Sigma, (I, \alpha, \gamma[\cdot, \kappa]))$  asserts: every behaviour of  $\Sigma$  whose input trajectory satisfies the assumption  $\alpha$  pointwise delivers the guarantee  $\gamma$  (with quantitative margin per the slack  $\kappa$  where declared). A wiring certificate  $\text{QWireCert}(w, (spec_i \Rightarrow spec_{out}, \kappa))$  asserts the lens square [37]: delivered upstream guarantees, degraded by at most  $\kappa$ , imply downstream assumptions through  $w$ , and the output spec reads off the delivered guarantees (the square’s discharge is  $\text{QWIRECERTDISCHARGE}$ ’s business). The rule: from  $\Sigma_i \models spec_i$  for  $i = 1, \dots, n$  and the wiring certificate, conclude  $\text{SysWire}(w, [\Sigma_1, \dots, \Sigma_n]) \models spec_{out}$ .

The warrant factors as  $\text{sound} = (T) \circ (S)$ : *transport arithmetic* — that composite obligation rows follow from component rows plus wiring rows — which is profile-generic exact polynomial arithmetic; and the *semantic reading* — that the checked row family implies the behavioural claim — which is per-profile, and is where the tier split and every open cell live.

**Lemma R78.1** (transport is profile-silent). *With residuals  $e_i := \mathcal{L}_i V_i + \alpha_i - \sigma_i$  and membership rows  $m_1 := \lambda \sigma_2 - (1-\theta)\alpha_1$ ,  $m_2 := \sigma_1 - \lambda(1-\theta)\alpha_2$ ,*

$$e_1 + \lambda e_2 + m_1 + m_2 = \mathcal{L}(V_1 + \lambda V_2) + \theta(\alpha_1 + \lambda \alpha_2),$$

*an identity of polynomials — the cross-supplies cancel by construction of the multipliers. More generally, for nonnegative certificate weights  $\lambda_i$  and free-sign wiring multipliers  $\nu_k$ : if each  $e_i \leq 0$  and each wiring identity  $g_k = 0$  holds on the operating region, then  $\sum_i \lambda_i e_i + \sum_k \nu_k g_k \leq 0$  there.*

*Proof.* The displayed identity is a two-line expansion; the only property of the obligation operator  $\mathcal{L}$  it consumes is *linearity over the wiring* — which every profile’s operator has:  $\nabla(\cdot) \cdot f$  for ODE, one-step conditional expectation minus identity for kernels, and the extended generator’s interior terms for GSHS. The pointwise fold is *admissible\_constructs*: each  $\lambda_i e_i \leq 0$  (nonnegative times nonpositive), each  $\nu_k g_k = 0$  regardless of sign, finite sums of nonpositives are nonpositive. At the sequent layer this is the PROMISE/SYZGYV machinery, and the small-gain instance is exactly the  $(1, \lambda, 1, 1)$ -weighted SYZGYV node — which is why the split of Remark R78.6 can define “admissible” as *syntactically constructible*: the composite certificate for the non-stochastic profiles is  $\sum_i \lambda_i V_i$ , and its row is this lemma. The break in uniformity, wherever it appears below, is never here: GSHS forced jumps contribute boundary rows, not  $\mathcal{L}$ -terms, so part of the composite obligation family bypasses linearity entirely and must be handled semantically.  $\square$

**Lemma R78.2** (conformance propagation — the acyclic engine). *Let a system presentation  $S$  have  $n$  components, and work in the composite behaviour space. Write  $\text{conform}_j$  for the event that component  $j$ ’s inputs conform to  $\alpha_j$ ,  $\text{sat}_j$  for delivery of  $\gamma_j$ , and  $\text{ext}$  for external-input conformance. Suppose the wiring squares transport, pointwise:  $\text{ext} \cap \bigcap_{i \in \text{upstream}(j)} \text{sat}_i \subseteq \text{conform}_j$  for every  $j$ . If at a behaviour  $\omega \in \text{ext}$  every component delivers on conformance ( $\omega \in \text{conform}_j \Rightarrow \omega \in \text{sat}_j$ ), then every component delivers at  $\omega$ .*

*Proof.* Strong induction on the causality rank ( $\text{sat\_of\_conform}$ ): if every component of rank  $< N$  delivers, then for  $j$  of rank  $< N+1$  all of  $j$ ’s upstream components have strictly smaller rank (the causality certificate), hence deliver; the wiring square then puts  $\omega \in \text{conform}_j$ , and the per-component implication closes. The causality certificate is precisely what makes the induction well-founded, and its necessity is a two-component counterexample: components in a cycle, each delivering *only if* the other does, satisfy every wiring square while both fail — the implication chain has no base case. That failure is the classical unsoundness of naive circular assume–guarantee [2, 177]; this calculus fences it structurally (cycles unrepresentable here) and readmits feedback only through the guarded small-gain cells of Lemma R78.4, where the well-foundedness device is the  $\theta$ -margin.  $\square$

**Lemma R78.3** (failure decomposition and slack composition). *Under Lemma R78.2’s wiring hypothesis, a composite failure under conforming external inputs localizes at some component that failed while conforming:*

$$\text{ext} \cap \left( \bigcap_j \text{sat}_j \right)^c \subseteq \bigcup_j (\text{conform}_j \cap \text{sat}_j^c),$$

*hence for any measure with per-component conforming-failure bounds  $\mu(\text{conform}_j \cap \text{sat}_j^c) \leq \varepsilon_j$ , the composite fails with mass at most  $\sum_j \varepsilon_j$  — the  $\sum_j (1 - p_j)$  display, at any  $n$ .*

*Proof.* Pick a rank-minimal failing component  $j_m$  (finitely many components; the failing set is nonempty). Every upstream component of  $j_m$  has strictly smaller rank, hence delivers (minimality), so the wiring square puts  $\omega \in \text{conform}_{j_m}$ : a conforming failure ( $\text{fail\_subset}$ ). Monotonicity and finite subadditivity of the measure close ( $\text{fail\_bound}$ ; read at an output spec,  $\text{fail\_bound\_out}$ ). The per-component event  $\text{conform}_j \cap \text{sat}_j^c$  — not bare failure — is forced: component  $j$ ’s certificate priced failure *only under conforming inputs*; charging it for non-conforming failures would demand a guarantee nobody certified, and the rank-minimality argument is exactly what shows the composite never needs one.  $\square$

**Lemma R78.4** (the stochastic-hybrid cells: series, parallel, feedback sum-form). *Over the composite execution law of a GSHS composite, with component certificates entering as nonnegative supermartingales along the (stopped) joint jump skeleton, with barrier values on*

their bad sets and violation-witness inclusions: (i, series) the conditioning tower composes — qualitatively, delivery a.e. on conforming inputs chains through the wiring square; quantitatively, an upstream success mass  $\geq p_1$  and a downstream conditional success probability  $\geq p_2$  — the conditional bound holding almost everywhere on the upstream success event, itself measurable in the conditioning  $\sigma$ -algebra — compose to composite success mass  $\geq p_2 \cdot p_1$  (stronger than the union-bound shape by exactly  $(1 - p_1)(1 - p_2) \geq 0$ ); and the certified pipeline bounds the composite conforming-failure mass by  $\int Y_1(0)/a_1 + \int Y_2(0)/a_2$  through the maximal inequality. (ii, parallel) for nonnegative weights, the weighted sum  $\sum_i \lambda_i V_i$  of supermartingales w.r.t. one (joint) filtration is a supermartingale — the semantic face of the syzygy weights — and the composite avoid bound follows through the same maximal inequality. (iii, feedback, sum-form) for two components in feedback whose certificates satisfy, along the joint skeleton, the between-jumps conditional decrease (pre-jump value plus integrated assumption-minus-supply increment conditionally below the current value) and non-expansive jump accounting (post-jump value a.e. at most pre-jump value), with the integrated membership rows of the small-gain pair at  $\lambda, \theta \geq 0$ : the composite  $W = V_1 + \lambda V_2$  is a nonnegative supermartingale for the joint-skeleton filtration, with the  $\theta$ -margin banked by the compensated process, and the composite avoid bound follows.

*Proof.* (i) is AGCompose.Series: the qualitative form is an a.e. implication chain through the pointwise wiring square (qualitative); the product form integrates the downstream conditional bound over the upstream event — the set-integral of the conditional expectation of the indicator over an upstream-measurable set is the joint mass (tower\_step, tower); the certified form (certified) converts each certificate to a failure bound via the maximal inequality for nonnegative supermartingales (Ville’s inequality, mechanized in the accompanying development) and composes by the failure decomposition. Exogeneity is where acyclicity earns its keep semantically: in a cascade each component’s input process is measurable w.r.t. upstream trajectories, so the component’s certificate argument runs pathwise in its input.

(ii) is AGCompose.Parallel: induction on the finite index set, scalar-multiple and sum closure of supermartingales (supermartingale\_weighted\_sum), then the barrier argument as in (i) (certified, certified\_pair).

(iii) is the file quoted above (SumFormFeedback): folding jump non-expansion into the between-jumps decrease gives the per-component skeleton step; the weighted combination of the two steps cancels the cross-supplies *under conditional expectation* — Lemma R78.1 run pointwise inside the conditional — leaving the  $\theta$ -weighted assumption margin (drift); nonnegativity and the supermartingale property assemble (supermartingale), and the avoid bound is the maximal inequality again (avoid\_bound, with the continuous-time reading conditional on the début-sampling inclusion, debut\_avoid\_bound). Two hypotheses deserve their remark. *The joint skeleton is not a convenience*: in feedback no component’s input is exogenous — the jump chain interleaves both components’ guard hits, each component’s between-jumps argument is valid only between joint jumps, and forced jumps, having no intensity, enter only through the jump-accounting field at those times. *Non-expansion is the sum-form’s load-bearing wall*: only  $\lambda, \theta \geq 0$  and the non-expansive accounting are consumed — no dwell-time or schedule hypothesis appears anywhere in the descent, which is a checkable structural fact about the statements — and the rule-level ranges  $\lambda > 0, \theta \in (0, 1)$  are well-formedness backing the published guard-modulus reading, not soundness needs.  $\square$

**Theorem R78.5** (the  $n$ -ary acyclic assembly). *Let  $S$  be an acyclic system presentation with wiring squares transporting pointwise as in Lemma R78.2. If each component delivers a.e. on conformance, the composite delivers its output spec a.e. on external conformance (QtslCompose.qualitative); and with per-component conforming-failure bounds  $\varepsilon_j$ , the composite output-spec failure mass is at most  $\sum_j \varepsilon_j$  (fail\_bound\_out) — at any  $n$ , by Lemmas R78.2 and R78.3.*

*Proof.* Immediate from the two lemmas: the a.e. form collects the countable family of per-component a.e. implications, applies the pointwise propagation on the common full-measure set, and reads the output spec off the delivered guarantees; the probabilistic form is the failure decomposition plus subadditivity. The per-profile content enters entirely through the *bridge hypotheses* — that the component-certificate events and their bounds exist over the composite law is the per-profile discharge of Lemma R78.4 (GSHS acyclic cells) or its lighter analogues; this theorem is the profile-generic event algebra on top.  $\square$

**Remark R78.6** (the tier split, derived — never a stored tag). The rule node’s tier is a function of the presentation (System.qagTier): *admissible* iff every mechanism’s derived profile admits a syntactically constructible composite certificate — proven equivalent to “every mechanism derives ODE or discrete” (qagTier\_admissible\_iff) — and *core* iff some mechanism is stochastic (qagTier\_core\_iff). On the admissible face the node unpacks: the composite certificate is  $\sum_i \lambda_i V_i$  (Lemma R78.1), transported at the sequent layer by the PROMISE/SYZYGY machinery, and the rule adds no semantic content. On the core face no unpacking exists — the warrant is Lemmas R78.2–R78.4 — which is the taxonomy’s definition of core applied honestly, one rule node either way. Deriving the tier from field-family population (rather than storing a system-level tag) is forced by mixed composites: a sampled-data plant-plus-controller would be ill-typed across its own components under any stored per-system tag.

**Remark R78.7** (what is *not* proven — the open cells, loud). The conditional mark on this rule’s dashboard row warrants exactly the cells above, and the honest remainder is: (a) the deterministic-ODE row’s semantic reading is at statement level (its literature anchor is the certified-lens composition theorem [37]; the classical comparison argument is standard but not yet written in-house); (b) the discrete-kernel row’s assembly is discharged —  $n$ -ary acyclic union-bound, parallel weighted-sum, and sum-form small-gain, end-to-end over the trajectory kernel (the width note’s dictionary names the statements) — with the *sampled-data* row the one still stated, not yet assembled (item (d)); (c) feedback in *gauge-form* — jumps that expand the certificate ( $V(g(x)) \leq cV(x)$ ,  $c > 1$ ), repaid by flow decay under schedule hypotheses — is partial: the gauge-then-sum reduction and the machine-checked max-form piecewise-deterministic instance are landed sorry-free, while the finite-index price of the diffusion term and the admissible-window pinch remain open research — though the reason the diffusion cell was *parked* is retired: within-segment supermartingale decay for gauged certificates is now available at the continuous-time martingale-problem profile (the battery family’s discharge), so what remains is the finite-index accounting and the window pinch themselves, not a missing stochastic calculus; sum-form composites provably do not cover this regime, which is exactly why the core tier exists. Non-expansive-reset models live entirely in Lemma R78.4(iii), so nothing below gates on (c); (d) the mixed sampled-data row is stated, not proven — deterministic throughout, the natural first boundary-row exercise; (e) undirected stochastic wire sharing (common noise) is *fenced*, not missing: stochastic

components sharing a wire need one determining side, and for fenced models no discharge of the joint-filtration hypothesis exists — the lemmas are correctly unusable there; (f) the  $n$ -ary *product-form* (tower) composition is binary only — its  $n$ -ary form needs a filtration chain along the wiring order and is real further work; (g) the judgment sorts the rule concludes into are not yet staged in the certificate schema, so no end-to-end checkable certificate exercises the rule yet. Each bridge hypothesis (the interface layers carrying a component certificate onto the composite law) is a named hypothesis discharged per model class — parameters, never silent assumptions.

*Remark R78.8* (relation to the literature). The acyclic discipline is the composing-specifications tradition [2], with circularity readmitted only under a well-foundedness device [177] — here the  $\theta$ -margin of the small-gain pair, whose Lyapunov formulation descends from the nonlinear small-gain theorems [125, 126]. The parallel cell is compositional dissipativity [184, 239] run at the satisfaction layer — the weighted-sum supermartingale is the stochastic face of the storage-function sum. The wiring square, its slack algebra, and the certified-lens composition law are [37]. What the mechanized grid adds over all of these is the certificate form: exact-arithmetic transport rows plus per-profile semantic lemmas with their hypotheses reified as checkable data, rather than a metatheorem quantified over models nobody replays.

## Rule 79. QWIRECERTDISCHARGE (core rule)

### The rule (Steele metanotation)

as realized in the mechanized development; source row: QTSL-rules.toml — *QWireCertDischarge*. The metanotation statement is typeset by hand for notational quality; its mechanized ground truth is the Lean statement below, extracted from the sources at every build of this book and hash-bound. The rule *roster* is machine-checked (every mechanized rule tag round-trips to exactly one catalogue row); the statement *text* is editorial, checked by eye against the extracted Lean beside it.

$$\frac{\begin{array}{l} \{R_\ell, \varphi(s) \wedge \alpha(v(s), a) \vdash \text{Lift}_s \varphi(u(s, a))\}_\ell, \{R_\ell, \varphi(s) \vdash \gamma(v(s))\}_\ell \text{ (mechanism-certification legs; } s \text{ a mechanism state, } a \text{ an admissible input)} \\ \{R_\ell \vdash \alpha_2(w(o_1), a_2) + \kappa(\gamma_1(o_1)) \geq \alpha_1(w^\#(o_1, a_2))\}_\ell \text{ (assumption legs)} \\ \{R_\ell \vdash \gamma_1(o_1) \geq \gamma_2(w(o_1))\}_\ell \text{ (guarantee legs)} \quad \vdash \kappa(0) = 0 \text{ (closed evaluation)} \\ [0, \infty) \vdash \kappa' \geq 0 \text{ (derivative-nonnegativity row)} \quad \vdash \deg \kappa > 0, \text{lead}(\kappa) \geq 0 \text{ (leading-coefficient row)} \end{array}}{\text{QWireCert}(w, (\text{spec}_i) \Rightarrow \text{spec}_{\text{out}}, \kappa)}$$

every leg family indexes over its posted proof leaves  $\ell$ , and each leaf binds its own region  $R_\ell$  as the antecedent of its sequent; the three arithmetic rows certify  $\kappa \in \mathcal{K}_\infty^0$  (zero at zero, monotone on the ray, unbounded).

$\mathcal{K}_\infty^0$  is the class under which slacks add and lenses compose; the premises are pointwise implications over polynomial data, one inherited BL sequent per posted leaf, the leaf's antecedent carrying its region — no region cover is stored on the node, and the obligation that the posted regions jointly cover the consuming composition's interface domain lives one row up, at the consumption site. The two Capucci-Myers condition families are the mechanism-certification legs (né chart certification) and the wiring-lens legs. No new checker machinery: the rule is leaf assembly, and its semantic content lives one row up in the composition rule.

QWIRECERTDISCHARGE is the wiring-certificate judgment's own discharge: it assembles a QWireCert — the license QWIRECOMPOSE consumes — entirely from inherited BL sequent leaves. Four condition families are checked, each indexing over its posted proof leaves  $\ell$ , and each leaf binds its own region  $R_\ell$  as the antecedent of its own sequent. The two *mechanism-certification legs* certify the component's contract at its mechanism:  $R_\ell, \varphi(s) \wedge \alpha(v(s), a) \vdash \text{Lift}_s \varphi(u(s, a))$  — the certified invariant, together with the assumption evaluated at the mechanism's readout and an admissible input, is preserved by the update — and  $R_\ell, \varphi(s) \vdash \gamma(v(s))$  — the invariant delivers the guarantee at the readout — where  $s$  ranges over the mechanism's state carrier and  $a$  over its admissible input carrier. The two *lens legs* certify the wiring square: the *assumption leg* (delivered upstream guarantees, degraded by at most the slack  $\kappa$ , imply the downstream assumption through the wiring map) and the *guarantee leg* (the upstream guarantee dominates the composite's output reading). For polynomial data all four are pointwise implications — ordinary sequents the base calculus already checks. Three further arithmetic rows certify the slack's class membership,  $\kappa \in \mathcal{K}_\infty^0$ : the constant coefficient is zero (closed evaluation), the derivative is nonnegative on the ray (a derivative-nonnegativity row), and the leading coefficient is positive at positive degree.

What the cited theorems warrant — and the scope of this entry's conditional check: that the three row families genuinely certify class membership (a polynomial passing them is zero at zero, monotone on  $[0, \infty)$ , and unbounded), and that the class supports the composition rule's slack algebra — slacks are closed under pointwise sum, closed under composition, the two-slack contract chain composes to the summed slack, and the guarantee legs chain along a cascade. That algebra is the quantitative content of “compose by lens composition and by addition of the slacks”.

Each membership row is load-bearing for the algebra. Drop zero-at-zero and a constant slack certifies a square that degrades even exact guarantee delivery — and the nonnegativity that anchors the additive algebra (a class slack is nonnegative on the ray *because* it is zero at zero and monotone) fails with it. Drop monotonicity and composition of slacks fails outright: the outer slack of a two-lens cascade need no longer bound the chained degradation, since a non-monotone  $\kappa_1$  can reward a worse input. Drop unboundedness and bounded candidates enter ( $\kappa \equiv 0$  passes the other two rows): the discharge then certifies membership in a class the slack does not belong to, and the published reading of  $\kappa$  as a reusable comparison-function-style gain is lost. The proof section walks each closure with the field it consumes.

**notes** Core-as-glue: the rule is leaf assembly, and the semantic content of what a wiring certificate *buys* lives one row up, in QWIRECOMPOSE's semantic reading. The non-strict monotone reading of the class follows the catalogue's own row roster (a derivative-nonnegativity row certifies monotone, not strictly increasing); the zero slack is thereby not a member — a slack-free square is a square with the  $\kappa$ -term absent, not with  $\kappa = 0$ . The judgment sort itself is baked in the extension theory; the mechanized warrant was proven ahead of the bake, and the square leaves are landed main-package sequent machinery, cited rather than re-bound here.

### Lean statement

**The slack class, bound by display.** `IsClassK0Inf` is the catalogue's  $\mathcal{K}_\infty^0$ : zero at zero, monotone on the nonnegative ray, unbounded at infinity. Its closure theorems (`add` — slacks add; `comp` — lenses compose) are proven in the same module inside the class namespace; `polynomial_discharge` maps the three checked row families onto the three fields, and `slack_triangle/guarantee_leg_comp` are the quantitative and guarantee-side composition faces.

BernsteinLogicAux.QtslCompose.WireCertDischarge . **polynomial\_discharge**

statement bound

```

/-- **The polynomial discharge** – the rule note's three membership rows, each
mapped to the class field it certifies:
1. zero-at-zero = closed evaluation ( $\text{'p.coeff } 0 = 0$ ', checked by evaluating);
2. monotone = the derivative-nonnegativity row ( $\text{'p' } \geq 0$  on the ray);
3. unbounded = positive leading coefficient (with positive degree).
A polynomial passing the three BL row families is genuinely a  $\mathcal{H}^0$  slack. -/
theorem polynomial_discharge (p : Polynomial  $\mathbb{R}$ )
  (h0 : p.coeff 0 = 0)
  (hderiv :  $\forall x : \mathbb{R}, 0 \leq x \rightarrow 0 \leq \text{p.derivative.eval } x$ )
  (hdeg :  $0 < \text{p.degree}$ ) (hlead :  $0 \leq \text{p.leadingCoeff}$ ) :
  IsClassK0Inf (fun x => p.eval x)

```

BernsteinLogicAux.QtslCompose.WireCertDischarge . **slack\_triangle**

statement bound

```

/-- **The additive slack triangle** (the quantitative face of "compose by
lens composition and by addition of the slacks"): two contract inequalities
with slack compose to one with the summed slack. Stated pointwise over an
arbitrary interface carrier – the per-region reading is  $\text{'X'}$  = the region. -/
theorem slack_triangle {X : Type*} {f g h : X  $\rightarrow \mathbb{R}$ } {c1 c2 :  $\mathbb{R}$ }
  (h1 :  $\forall x, f x \leq g x + c1$ ) (h2 :  $\forall x, g x \leq h x + c2$ ) :
   $\forall x, f x \leq h x + (c1 + c2)$ 

```

BernsteinLogicAux.QtslCompose.WireCertDischarge . **guarantee\_leg\_comp**

statement bound

```

/-- The guarantee-side lens leg composes (the  $\kappa$ -free leg of the CM square:
 $\gamma_1 \geq \gamma_2 \circ w$  chains along a cascade). -/
theorem guarantee_leg_comp {A B C : Type*} {w1 : A  $\rightarrow$  B} {w2 : B  $\rightarrow$  C}
  { $\gamma_1 : A \rightarrow \mathbb{R}$ } { $\gamma_2 : B \rightarrow \mathbb{R}$ } { $\gamma_3 : C \rightarrow \mathbb{R}$ }
  (h1 :  $\forall a, \gamma_2 (w1 a) \leq \gamma_1 a$ ) (h2 :  $\forall b, \gamma_3 (w2 b) \leq \gamma_2 b$ ) :
   $\forall a, \gamma_3 (w2 (w1 a)) \leq \gamma_1 a$ 

```

BernsteinLogicAux.QtslCompose.WireCertDischarge . **nonneg**

statement bound

```

/-- A  $\mathcal{H}^0$  slack is nonnegative on the nonnegative ray. -/
theorem nonneg (h : IsClassK0Inf  $\kappa$ ) {x :  $\mathbb{R}$ } (hx :  $0 \leq x$ ) :  $0 \leq \kappa x$ 

```

BernsteinLogicAux.QtslCompose.WireCertDischarge . **add**

statement bound

```

/-- **Slacks add** ("by addition of the slacks"): the class is closed under
pointwise sum. -/
theorem add (h1 : IsClassK0Inf  $\kappa_1$ ) (h2 : IsClassK0Inf  $\kappa_2$ ) :
  IsClassK0Inf (fun x =>  $\kappa_1 x + \kappa_2 x$ )

```

BernsteinLogicAux.QtslCompose.WireCertDischarge . **comp**

statement bound

```

/-- **Lenses compose** : the class is closed under composition (the slack of a
two-lens cascade). -/
theorem comp (h1 : IsClassK0Inf  $\kappa_1$ ) (h2 : IsClassK0Inf  $\kappa_2$ ) :
  IsClassK0Inf ( $\kappa_1 \circ \kappa_2$ )

```

BernsteinLogicAux.QtslCompose.WireCertDischarge . **IsClassK0Inf**

definition bound

```

/-- Class  $\mathcal{H}^0$  membership (the  $\text{'QWireCert'}$  slack class): zero at zero,
monotone on the nonnegative ray, unbounded at infinity. -/
structure IsClassK0Inf ( $\kappa : \mathbb{R} \rightarrow \mathbb{R}$ ) : Prop where
  zero_at_zero :  $\kappa 0 = 0$ 
  mono : MonotoneOn  $\kappa$  (Ici 0)
  unbounded : Tendsto  $\kappa$  atTop atTop

```

## Correspondence (Steele display $\leftrightarrow$ Lean)

**reviewer-certified against the displayed texts** The dictionary below is a reviewer-certified statement of how the mechanized statements above interpret the displayed rule: display metavariable  $\mapsto$  Lean binder, each display hypothesis  $\mapsto$  the premise or side condition carrying it, the display conclusion  $\mapsto$  the goal — with any deliberate difference in width between display and mechanization named outright. Certification is recorded as a hash triple over (the displayed cell, the extracted statement texts, this dictionary's own text); if any of the three changes, this block turns amber

until a reviewer re-certifies. The correspondence claim itself remains editorial — reviewer-grade, not machine-checked; its machine-checked successor types each soundness statement against the rule as a structured object, and supersedes this block per rule as it lands.

The displayed conclusion  $\text{QWireCert}(w, (\text{spec}_i) \Rightarrow \text{spec}_{\text{out}}, \kappa)$  is concluded by *no* bound statement — deliberately: the judgment sort lives theory-side (the note), the square leaves are landed sequent machinery cited as witness prose, and what this bound set certifies is the *semantic warrant behind the arithmetic rows* plus the class algebra the rule's composition claims lean on. The class itself is bound by display:  $\text{IsClassK0Inf} = \text{zero-at-zero} + \text{Monotone0n } \kappa \text{ (Ici } 0) + \text{Tendsto } \kappa \text{ atTop atTop} \text{ — } \mathcal{K}_{\infty}^0$  as the catalogue reads it, non-strict monotone (the note's ruling, visible in the field type).

- the three membership rows  $\mapsto$  `polynomial_discharge`, one hypothesis per row per field: closed evaluation  $\mapsto$  `p.coeff 0 = 0  $\Rightarrow$  zero_at_zero`; derivative-nonnegativity on the ray  $\mapsto$  `hderiv  $\Rightarrow$  mono` (through the mean-value machinery `monotone0n_of_deriv_nonneg`); leading-coefficient row  $\mapsto$  `0 < p.degree + 0  $\leq$  p.leadingCoeff  $\Rightarrow$  unbounded`. The displayed row asks only `lead( $\kappa$ )  $\geq$  0` and so does the statement — nonstrict suffices because a degree-witnessing leading coefficient is nonzero by definition; the commentary's “positive” is the derived fact, not an extra demand.
- “slacks add, lenses compose”  $\mapsto$  `slack_triangle` (two contract inequalities chain to the summed slack, stated pointwise over an arbitrary carrier — the per-region reading is the carrier choice) and `guarantee_leg_comp` (the  $\kappa$ -free guarantee leg chains along a cascade). The class *closure* lemmas `IsClassK0Inf.add` and `IsClassK0Inf.comp` (with the nonnegativity anchor `IsClassK0Inf.nonneg`) are bound with the entry and carry the commentary's closure claims (sum, composition), alongside the triangle and the guarantee leg.
- polynomiality of  $\kappa \mapsto$  `p : Polynomial  $\mathbb{R}$`  in the discharge theorem only; the class and its algebra are stated for arbitrary  $\mathbb{R} \rightarrow \mathbb{R}$  functions — wider than the display's polynomial slacks, safe direction.

Width note: the four leaf families of the display map onto the baked node's two proof lists — the mechanism-certification legs (both shapes) ride `QWireCertDischarge/mech_rows`, and the assumption and guarantee lens legs ride `QWireCertDischarge/lens_rows` — with every leaf's own  $R_{\ell}$  as its sequent's antecedent. In the bound set the lens legs appear only through their compositional shadows (`slack_triangle`, `guarantee_leg_comp`); the per-leaf discharge of all four families is inherited BL sequents, main package, outside this page's bindings — the package-boundary rule, stated in the module header.

## Lean verifier receipts

module BernsteinLogicAux.QtslCompose.WireCertDischarge; bound build cec5cc1749e1... (bound from receipt 90dcbae3ace744d7, 2026-07-19T18:24:58Z). A receipt records that named checking layers accepted a build: (module, compiled-artifact SHA-256, environment SHA-256, checker layers), minted when the checking gate ran; the store receipts attesting the bound build are listed with the layers each run credited. Nothing here asks the reader to trust the store: every layer is an independently runnable program over the quoted sources — rebuild the module and re-run the checkers to reproduce the verdict. Receipts attesting superseded builds credit no layer and are omitted from this rendering (the count of omissions, if any, is noted below).

## HOL4 statement

**NO HOL STATEMENT YET**

The satisfaction-judgment extension postdates the HOL4 port entirely: the ported cone is the base calculus's check-function surface (theory `bern_catalogue`), and no extension-theory definition exists in the HOL development — in particular nothing shaped like a wiring-certificate discharge. The rule's sequent *leaves* would already be expressible in the ported vocabulary, but the judgment they assemble would not; the box waits on a HOL port of the satisfaction stratum.

**HOL verifier receipts****NONE**

no HOL verification receipt exists for this rule.

**Proof**

Genre: core rule (tier 1), core-as-glue — the rule assembles inherited sequent leaves into the wiring-certificate judgment, and its own mathematical content is deliberately thin: that the checked arithmetic rows genuinely certify slack-class membership, and that the class supports the composition algebra the composition rule recomputes. The section proves exactly that and marks the assembly gap loudly.

**Setting and claim.** A wiring certificate  $\text{QWireCert}(w, (\text{spec}_i \Rightarrow \text{spec}_{\text{out}}, \kappa)$  carries two per-region families of pointwise implications — the lens square's assumption  $\text{leg } \alpha_2(w(o_1), a_2) + \kappa(\gamma_1(o_1)) \geq \alpha_1(w^\sharp(o_1, a_2))$  and guarantee  $\text{leg } \gamma_1(o_1) \geq \gamma_2(w(o_1))$  [37] — which for polynomial data are ordinary sequents the base calculus checks, plus a slack  $\kappa \in \mathcal{K}_\infty^0$ : zero at zero, monotone on  $[0, \infty)$ , unbounded at infinity (the `IsClassK0Inf` structure quoted above; the non-strict monotone reading is the catalogued one). The rule's own obligations, proven here: the three checked rows certify membership for polynomial slacks (Lemma R79.1), and the class supports “compose by lens composition and by addition of the slacks” (Lemma R79.2).

**Lemma R79.1** (the polynomial discharge). *Let  $p$  be a real polynomial with (R1) constant coefficient zero, (R2) derivative nonnegative on  $[0, \infty)$ , and (R3) positive degree with nonnegative leading coefficient. Then  $x \mapsto p(x)$  is in  $\mathcal{K}_\infty^0$ .*

*Proof.* (`polynomial_discharge`.) Zero at zero:  $p(0)$  is the constant coefficient, so (R1) is the field it certifies — and note the checker's form of (R1) is one closed exact evaluation, the ground-fact pattern. Monotone:  $[0, \infty)$  is convex and  $p$  is everywhere continuous and differentiable, so nonnegativity of  $p'$  on the interior gives monotonicity on the ray (the mean-value inequality); (R2) is a single-variable nonnegativity row of exactly the calculus's cone-checkable shape. Unbounded: a polynomial of positive degree with nonnegative leading coefficient tends to  $+\infty$  — (R3) is one syntactic degree check plus one sign row. Each row maps onto exactly one class field; none is spare.  $\square$

**Lemma R79.2** (the slack algebra).  *$\mathcal{K}_\infty^0$  is closed under pointwise sum and under composition; two contract inequalities with constant slacks chain to one with the summed slack ( $f \leq g + c_1$  and  $g \leq h + c_2$  pointwise give  $f \leq h + (c_1 + c_2)$ ); and guarantee legs chain along a cascade ( $\gamma_2 \circ w_1 \leq \gamma_1$  and  $\gamma_3 \circ w_2 \leq \gamma_2$  give  $\gamma_3 \circ w_2 \circ w_1 \leq \gamma_1$ ).*

*Proof.* Sum (`IsClassK0Inf.add`): zeros add; monotonicity is termwise; for unboundedness, eventually the second summand is non-negative (it tends to infinity), so the sum eventually dominates the first, which tends to infinity. Composition (`IsClassK0Inf.comp`):  $\kappa_1(\kappa_2(0)) = \kappa_1(0) = 0$ ; monotone-composed-monotone is monotone *provided the inner map lands in the outer's domain of monotonicity* — which is where nonnegativity of a class slack on the ray (zero at zero plus monotone) is consumed, not decoration; unbounded-composed-unbounded is unbounded. The triangle (`slack_triangle`) and the guarantee chain (`guarantee_leg_comp`) are one-line pointwise transitivity, stated over an arbitrary interface carrier so the per-region reading is instantiation, not generalization. In application the “constants” are the slack values at the delivered guarantees — the triangle is applied pointwise per region — while composing the slack *functions* of a cascade is the closure pair's job.  $\square$

**Remark R79.3** (why each membership row is load-bearing). Drop (R1) and  $\kappa(x) = x + 1$  enters the class candidates: a wiring square then certifies with degradation even on *exact* upstream delivery ( $\kappa(0) = 1$ ); and the anchor of the algebra — nonnegativity of a class slack on the ray, proved from zero-at-zero plus monotonicity — fails too, witness  $\kappa(x) = x - 1$ . Drop (R2) and  $\kappa(x) = x^2 - x$  enters (zero at zero, positive degree, positive lead): negative on  $(0, 1)$ , so the nonnegativity anchor fails, and non-monotone, so composition closure fails at the monotonicity step (Lemma R79.2's proof consumes it twice: once as the outer map's field, once through inner-map nonnegativity), and the quantitative reading — a weaker delivered guarantee never *shrinks* the licensed degradation — inverts. Drop (R3) and bounded slacks enter ( $\kappa \equiv 0$  passes (R1)–(R2) alone); the discharge then no longer certifies unboundedness, and  $\kappa$  loses its comparison-function-style gain reading. The zero polynomial is excluded by (R3) deliberately: a slack-free square is a square with the  $\kappa$ -term *absent*, never one with  $\kappa = 0$ , so the additive algebra needs no zero element.

**Remark R79.4** (the assembly gap, loud). What this section does *not* contain: the square leaves themselves (landed sequent machinery of the base calculus, cited by the certificate — pointwise polynomial implications per region, checked by the cone machinery), and the end-to-end assembly of the judgment object, which awaits the staging of the judgment sort in the certificate schema. The dashboard's conditional mark scopes the warrant to exactly Lemmas R79.1 and R79.2: the arithmetic rows mean what they claim, and the class composes. The semantic content of what a wiring certificate *buys* a composite is deliberately not here — it is the composition rule's semantic reading, one section over.

## Rule 80. QWIRECOMPOSEMARKS (core rule)

### The rule (Steele metanotation)

as realized in the mechanized development; source row: QTSL-rules.toml — *QWireComposeMarks*. The metanotation statement is typeset by hand for notational quality; its mechanized ground truth is the Lean statement below, extracted from the sources at every build of this book and hash-bound. The rule *roster* is machine-checked (every mechanized rule tag round-trips to exactly one catalogue row); the statement *text* is editorial, checked by eye against the extracted Lean beside it.

$$\{\Sigma_i \models (I_i, A_i, E_i)\}_{i=1}^n \quad \text{where } A_i \equiv \bigwedge_{j \in \text{in}(i)} \text{ev}(g_j) \text{ PathPred}, \quad E_i \equiv g_i \\ \{\ell_i \text{ latency rows}\}_{i=1}^n \quad (\text{each premise ships its } \text{QWireCert}(w, (\text{spec}_i)_i \Rightarrow \text{spec}_{\text{out}}, -))$$

MarkFlow( $w, (t_k)_k, (P_k)_{k \in \text{cyc}_0(w)}$ ) (the schedule walk, two columns: stage rows — difference-constraint feasibility at the labels; carve rows — W0 (composite properness — the existing family; the

SysWire( $u$

the  $\exists$ -face sibling of QWIRECOMPOSE: same wiring premise vocabulary, opposite polarity economics. **No causality certificate, no ranks, no guard column** — a dip under a mark survives every extension, so a cyclic wiring conspires *for* the conclusion, and the well-foundedness kit appears precisely in the rule whose conclusion face is ForallSpec, never here. In its place, one composite-level ingredient in two columns: the MarkFlow walk — the  $\exists$ -dual of the causality walk, same arithmetic species (difference constraints over the declaration closure, bounded recompute), opposite verdict role: the  $\forall$ -walk demands strict increase along every wire, refusing all cycles; this walk demands *consistency*, admitting every cycle whose schedule closes and refusing time-travel. Its stage arithmetic forces every dependency cycle to total lag zero with one shared label — so the cycles the rule admits are exactly the instantaneous self-supporting loops, and there the walk's carve column takes over: producer-supplied *carves* (one predicate per cycle mark, presented as a scalar-codomain gate hypernet cited by digest — its sign-fiber the carve; a plated aggregate gate for token-population members; never a trace, and never a bare point of a continuous state space) checked by containment arithmetic, carved-delivery citations, and one diagonal certificate per cycle asserting the instant loop closes jointly *inside* the carve product — the discriminant carve-invariance alone provably misses. Exact value pins survive as the degenerate diagonal species, honest exactly where states are finitely presentable. Off the cycles no carve is needed: the  $\forall\exists$  premises chain deliveries in topological order, producer-side — and the premises themselves are the maximal-carve rows, so the whole column is the rule's own premise form run at tighter predicates. The conclusion is root satisfaction with the demanded marks in the record's ExistsSpec list — one turnstile, no subscript; the face lives in the argument. The joint witness (record, joint law, PDE solution) is constructed once, inside the soundness metatheorem, and never appears on the wire. Guarded premises are not exempt: the composition consumer eliminates each component guard at consumption — initial membership discharged before the premise is read as a guarantee — exactly as at QWIRECOMPOSE (the mirrored elimination row).

QWIRECOMPOSEMARKS is the satisfaction stratum's composition rule for cyclic wiring at the liveness face — the polarity complement of QWIRECOMPOSE, whose causality certificate makes a directed cycle unrepresentable. The polarity fact underneath: a safety violation and a mark realization are both finite-stage events with opposite persistence. A violation poisons every extension, so circular reasoning about guarantees-as-floors needs a well-foundedness device; a dip under a mark survives every extension, so a cycle's self-support is productive — the two-relay loop that refutes the unguarded circular safety rule is, read at the mark face, exactly the witness that realizes “both outputs hit 1.” Accordingly this rule carries *no causality certificate, no ranks, no guards*: from per-component conditional-delivery judgments (every admitted resolution whose interface conforms to the assumed in-neighbour marks admits some resolution through it realizing the own mark — with a properness presupposition on the conforming sub-body), their latency rows, the wiring plumbing, one mark-entailment sequent, the MarkFlow walk, and the properness family, it concludes satisfaction of the wired composite at an output spec whose demanded content is its record's ExistsSpec list.

The one composite-level ingredient is the walk, and it runs in two columns of the same arithmetic species — bounded recompute over the declaration closure, never chase derivation, no well-foundedness anywhere. The *stage column* is the causality walk's  $\exists$ -dual: producer-supplied stage labels per mark, checked against the difference-constraint system the latency rows induce — where the  $\forall$ -walk demands strict increase along every wire (refusing all cycles), this walk demands consistency, admitting every cycle whose schedule closes and refusing time-travel (a relay against an initialized unit delay demands  $t_x = t_y$  and  $t_y = t_x + 1$  at once). Its own arithmetic forces every admitted cycle to total lag zero and one shared label — so the admitted cycles are precisely the instantaneous self-supporting loops. There the *carve column* takes over: producer-supplied carves — one *predicate* per cycle mark, presented as a scalar-codomain gate hypernet cited by digest, its sign-fiber the carve; a plated aggregate gate where the members are token-population systems; never a trace, and never a bare point of a continuous state space — checked by three row families: containment (the carve refines its mark), carved-delivery citations of the very premises the rule already holds (instantiated at the carve events), and one *diagonal* certificate per cycle, asserting the instant loop closes jointly inside the carve product. The diagonal is the load-bearing novelty: carve-invariance alone provably misses it, and exact value pins survive as its degenerate species — honest exactly where states are finitely presentable, which is the reason the column generalized. The premises themselves are the maximal-carve rows (machine-checked as an equivalence), so the whole column is the rule's own premise form run at tighter predicates — a dial from the sketch's judgments down to points. The proof section derives both columns from countermodels:

delete the stage column and the relay-delay loop concludes falsely; delete the diagonal and the swap loop with a swap-closed mark — the relay loop's evil twin, distinguishable by delivered content alone — concludes falsely while every premise holds, *including carve-invariance at every carve*. Both refutations, the refuse/admit pairs, the discriminant pair, and the subsumption of pins by carves are machine-checked.

The soundness warrant is a metatheorem whose joint object — record, joint law, or solution, per profile — is constructed once in the proof and never appears on the wire. The mechanized instance is the discrete-relational tier: the assembly engine in carved form (carve rows + schedule + seriality + diagonal closure produce a joint run realizing every mark at its label, by stage recursion — the walk's rows align every in-neighbour of a marked component at its own label, where the carve-at-label invariant holds, so the carved-delivery rows discharge the marked constraints; the pinned engine is re-derived through it at singleton carves), and the chaining bridge at both ends of the dial (on acyclic-instant networks the conditional-delivery premises alone conclude — via derived points, and equally via the maximal carve with no diagonal presented — so the carve column enters the wire only where a cycle genuinely closed). The diagonal's per-species discharge splits the labor the way the stochastic tier already does: the checker verifies finite species rows (a witness point, a bounded enumeration, Lipschitz/gain rows with cycle product below one, convexity or order-interval flags), and the fixpoint theorem that converts them into joint solvability — exhaustion, Banach, Kakutani, Tarski — lives in the metatheorem, per profile, proved once. Properness earns a tier note: the liveness construction consumes *stepwise* properness (the composite stays live at every stage, given the schedule's pins), because bare nonemptiness of the behaviour set is witnessed by runs the construction cannot use — blocking components and pin-sensitive instant subsystems are the countermodels, named in the proof section.

Two fences are part of the statement. Marks are single-dip graded-reach demands — finitely realizable, extension-persistent; recurrence-shaped liveness (Streett-class acceptance around cycles) stays outside both cyclic variants. And the rule deliberately trades completeness for finite presentation: a component delivering only on its favourite conforming input can witness a joint behaviour that no conditional-delivery premise certifies — certifying such composites without presenting behaviours is the strategy form, future work.

**notes** The classical anchors sit on the safety side: circular assume-guarantee is unsound for safety without a well-foundedness device [2], and the standard repairs induct over time [177]. This rule is the observation that the liveness-mark fragment of the specification language needs no such device at all — greatest-fixpoint territory, where the walk replaces the ranking: schedules must close around cycles (and deliveries must agree around the instantaneous ones — agreement certified over carved predicates, with exact values as the degenerate species) rather than cycles being forbidden to close. The certificate carries judgments, stage labels, gate-hypernet digests with their containment, delivery, and diagonal rows, and one sequent; nothing behaviour-sized. Mechanization posture, stated loudly: the discrete-relational tier is proven end-to-end in carved form with the pinned form subsumed (the Lean cells below, sorry-free, standard axiom closures); stochastic and PDE instances of the metatheorem, the per-species diagonal devices at continuous tiers (Banach for the contraction species, Kakutani for the convex, Tarski for the order-theoretic), the history-dependent mechanism tier, and the general difference-constraint walk are open, and the schema realization (an additive sibling node kind beside the acyclic rule's, carrying premise citations, latency rows, the two-column walk as a side condition, and the reused properness family) is staged for the extension theory's next revision, which is why this entry's dashboard row shows a catalogued rule ahead of its wire format.

## Lean statement

**The discrete-relational tier, bound whole.** The engine, the chaining bridge, and the battery — the hypotheses-necessity refutations are first-class bound statements, not test scaffolding: the rule's two walk columns each carry their forcing countermodel in the same module that proves the repaired kit sound.

BernsteinLogicAux.QtslCompose.AGComposeMarks . marks\_of\_pinned\_delivery

statement bound

```
/-- **The assembly engine** (the soundness metatheorem's discrete-relational
instance, pinned form): pin rows + schedule walk + seriality + schedule-relative
instant closure produce a joint run realizing every mark at its label. The
joint behaviour exists only under this conclusion's binder. -/
theorem marks_of_pinned_delivery (hser : Serial N) (hfeas : MarkFlowFeasible N t)
  (hpin : PinnedDelivery N mark a) (hclose : InstantClosure N a t) :

## Correspondence (Steele display ↔ Lean)

the Steele display and a bound Lean statement and the dictionary text **CHANGED** since certification — re-review and re-certify The dictionary below is a reviewer-certified statement of how the mechanized statements above interpret the displayed rule: display metavariable  $\mapsto$  Lean binder, each display hypothesis  $\mapsto$  the premise or side condition carrying it, the display conclusion  $\mapsto$  the goal — with any deliberate difference in width between display and mechanization named outright. Certification is recorded as a hash triple over (the displayed cell, the extracted statement texts, this dictionary's own text); if any of the three changes, this block turns amber until a reviewer re-certifies. The correspondence claim itself remains editorial — reviewer-grade, not machine-checked; its machine-checked successor types each soundness statement against the rule as a structured object, and supersedes this block per rule as it lands.

The display is the rule at the satisfaction stratum; the bound set is its soundness metatheorem's discrete-relational instance, over an explicit network model ('MarkNet': in-neighbour sets, per-component delivery lags, memoryless admitted-output relations over wire snapshots, initial segments; 'JointRun' the per-stage constraint satisfaction). The dictionary, display constituent by bound statement:

- the conditional-delivery premises  $\Sigma_i \models (I_i, A_i, E_i) \mapsto \text{ConditionalDelivery}$  (every mark-conforming snapshot admits an own-mark output through it) — the memoryless instantiation; the latency rows' seriality obligation  $\mapsto \text{Serial}$ ; dep-locality (a component reads only its declared in-neighbours)  $\mapsto \text{DepLocal}$ .
- the MarkFlow stage column  $\mapsto \text{MarkFlowFeasible}$  — the walk's Lean *specification* at the exact-lag row shape ( $t_i = t_j + \text{lag}_i$  per in-edge,  $\text{lag}_i \leq t_i$ ); the general difference-constraint species (windows, rational stages) is the wire format's and is honestly absent here.
- the carve column's row families  $\mapsto \text{CarvedDelivery}$  (containment + carved delivery: every snapshot with in-neighbour reads inside the carves admits an output in the own carve) and  $\text{CarveClosure}$  (the diagonal: at every stage, for every carve-conforming base, the instant subsystem closes jointly with labeled coordinates in-carve and admitted) — the latter consumed *abstractly*: its per-species certificate dischargers are the wire format's, its fixpoint devices the metatheorem's. The r4 value column  $\mapsto \text{PinnedDelivery} + \text{InstantClosure}$ , subsumed as the singleton case by  $\text{carvedDelivery\_of\_pinned} / \text{carveClosure\_of\_pinned} / \text{marks\_of\_pinned\_delivery\_via\_carve}$ ; the premises themselves are the maximal-carve rows,  $\text{carvedDelivery\_mark\_iff\_conditional}$ .
- the W0-species rows  $\mapsto \text{InstantClosure} / \text{CarveClosure}$  (schedule-relative stepwise properness) — deliberately STRONGER than bare nonemptiness, the tier discharge the construction consumes; the unpinned form  $\text{W0Serial}$  appears only in the refuted premise-only statements, to make those refutations as strong as possible.
- the conclusion  $\mapsto$  the existential in  $\text{marks\_of\_carved\_delivery} \text{ (engine)} / \text{marks\_of\_conditional\_delivery\_acyclic} + \text{marks\_acyclic\_via\_maximal\_carve}$  (both dial ends of the acyclic case): some  $\text{JointRun}$  realizes every mark at its label (the joint witness under the binder, never a hypothesis).
- the countermodel battery, as prereg'd mutants:  $\text{z1\_refutes\_walkless} / \text{z1\_refutes\_walkless\_carve}$  (stage column deleted, at value and carve level),  $\text{z5\_refutes\_pinless} / \text{z5\_refutes\_closureless}$  (pin/diagonal column deleted — against kits with  $\text{W0Serial}$  and composite nonemptiness granted), the discriminant pair  $\text{z5\_carvedDelivery\_mark}$  (invariance holds on the swap loop) /  $\text{z5\_no\_carve\_closure}$  (no carve inside the marks closes its diagonal),  $\text{z5\_no\_pin}$  (its singleton shadow),  $\text{z1\_walk\_infeasible} / \text{allOnes\_walk\_feasible}$  (the walk's refuse/admit pair),  $\text{allOnes\_marks\_realized}$  (positive control through the pinned engine) +  $\text{allOnes\_direct}$  (independent witness) +  $\text{fatCarve\_marks\_realized}$  (positive control through the carved engine at a non-singleton carve — no hypothesis names a value).

Width note: the conditional mark's content is the tier gap stated in the commentary — within the mechanized tier the mappings above are exact, the engine is proven at general lags, and the mark-entailment sequent is consumed at its identity instance (the conclusion realizes the premises' own marks; the cut against a distinct output-spec mark list is sequent-layer machinery, not this module's).

## Lean verifier receipts

module BernsteinLogicAux.QtslCompose.AGComposeMarks; no attested build yet; source-bound only. The statements above are hash-bound to the source file, but no build attestation exists for this module yet, so no receipt can be judged to attest the quoted build.

**NO ATTESTED BUILD BOUND for this module** 7 receipt(s) in the store attest superseded builds of this module and are omitted from this rendering. module BernsteinLogicAux.QtslCompose.AGComposeCarves; no attested build yet; source-bound only. **NO ATTESTED BUILD BOUND for this module** 6 receipt(s) in the store attest superseded builds of this module and are omitted from this rendering.

gate-layer coverage of the bound build:

build (lake build (elaboration)) **stale only**  
 replay (leanchecker (official kernel replay)) **none**  
 hardened (safe\_verify (hardened screen)) **none**  
 decorrelated (lean4export + nanoda (decorrelated kernel)) **stale only**

**comparator: none** no fixture in the three-implementation comparator harness (compiled / kernel-interpreted / reference-interpreted) exercises this rule.

## HOL4 statement

### NO HOL STATEMENT YET

The satisfaction-judgment extension postdates the HOL4 port entirely (the ported cone is the base calculus's first-order check-function surface), and this rule's wire format is itself staged ahead of the schema — there is no wire checker for a HOL statement to mirror yet. The box inherits QWIRECOMPOSE's honest state one rule further out.

## HOL verifier receipts

### NONE

no HOL verification receipt exists for this rule.

## Proof

Genre: core rule (tier 1). The soundness warrant is a metatheorem whose joint witness never appears on the wire; this section proves it at the discrete-relational tier — the tier the mechanization proves — and derives every certificate row from a countermodel that breaks the rule without it. Per-profile instances beyond this tier are stated as open, never claimed.

**Setting and claim.** The acyclic composition rule's causality certificate makes a directed cycle unrepresentable; this rule is its polarity complement, existing precisely to admit cyclic wiring — for *liveness marks only*. The polarity fact that makes this sound where the safety analogue fails: a safety violation and a mark realization are both finite-stage events with opposite persistence. A violation of a prefix-closed guarantee poisons every extension, so under a  $\forall$ -reading a cyclic wiring can conspire to admit a bad behaviour and a well-foundedness device is mandatory. A dip under a mark survives every extension, so under an  $\exists$ -reading the same conspiracy works for the conclusion: circular self-support is a post-fixpoint, productive rather than vicious. The rule concludes  $\text{SysWire}(w, [\Sigma_1, \dots, \Sigma_n]) \models \text{spec}_{\text{out}}$  where the output spec's demanded content is its record's ExistsSpec list — one turnstile, no subscript: the face lives in the argument. Premises: per-component *conditional delivery* (for every admitted resolution whose interface conforms to the assumed in-neighbour marks, some admitted resolution through it realizes the own mark — the  $\forall$ -conforming- $\exists$ -delivering reading, with a properness presupposition on the conforming sub-body), each shipping its *latency row* (delivery-stage arithmetic at its own profile tier); the wiring certificate's plumbing; one mark-entailment sequent  $\Lambda_i g_i \vdash \text{marks}(\text{spec}_{\text{out}})$ ; the MarkFlow walk in two columns (below); and the W0-species properness rows.

*Remark R80.1* (the walk, stage column: what breaks without it). Take a relay (out  $\equiv$  in, instantaneous) closed against a unit delay initialized to 0, marks “hits 1” on both wires. Both conditional-delivery premises are true — a relay fed a trace hitting 1 emits one; a delay shifts a hit by one stage — and the composite is proper. But its unique behaviour is all-zeros: the initialization propagates around the cycle forever, and the conclusion is false. Premise shape alone is therefore unsound; something composite-level is forced. The forced ingredient is *schedule arithmetic*: the producer supplies one stage label  $t_k$  per mark, and the checker verifies the finite difference-constraint system assembled from the latency rows — label equality across instantaneous wires, shifts through delay media. The relay-delay loop is refused exactly here: its rows demand  $t_x = t_y$  and  $t_y = t_x + 1$ , infeasible — while the loop of two relays passes at the shared label 0. This is the  $\exists$ -dual of the causality walk: the same arithmetic species (difference constraints over the declaration closure, bounded recompute, never chase derivation), the opposite verdict role — the  $\forall$ -walk demands strict increase along every wire, refusing all cycles; this walk demands consistency, admitting every cycle whose schedule closes. Feasibility of difference constraints is a Bellman-Ford-class check, not an induction device: no well-foundedness enters. Mechanized: `z1_refutes_walkless` (every other hypothesis of the pinned engine true, conclusion false), with the refuse/admit pair `z1_walk_infeasible / allOnes_walk_feasible`.

*Remark R80.2* (the walk, value column: what breaks without it). The stage column has a blind spot, and it is exactly where this rule lives. Around any dependency cycle the latency rows sum, so a feasible schedule forces every cycle to total lag zero and one shared label: the admitted cycles are the instantaneous self-supporting loops, whose marks all land at one instant. There the  $\exists$ -chosen delivery *values* must agree around the loop — and no stage arithmetic can see values. Witness: a pointwise swap

gate over  $\{0, 1, 1'\}$  ( $1 \mapsto 1', 1' \mapsto 1, 0 \mapsto 0$ ) closed against a relay, with mark “hits  $\{1, 1'\}$ ” on both wires — a mark set closed under the swap. Every remaining hypothesis holds: both conditional deliveries (the swap maps the mark set into itself; the relay copies it), the schedule ( $t_x = t_y = 0$ ), properness (all-zeros — 0 is the swap’s fixpoint), even joint instant seriality. But every joint run satisfies  $x = \text{swap}(x)$  around the loop, hence is all-zeros, and the conclusion is false: the swap loop is the relay loop’s evil twin, distinguished by values alone. The forced repair is the walk’s *value column*: on each zero-lag cycle the producer supplies a *pin*  $\alpha_k$  per mark — the delivered value, spec-representable and label-sized, the value analogue of  $t_k$ , never a trace — and the checker verifies mark membership per pinned wire plus *pointed delivery*: each pinned component’s conditional-delivery judgment cited at the pins (through every conforming input agreeing with the neighbouring pins, the own pin is admitted). The relay loop passes ( $\alpha_x = \alpha_y = 1$ ); the swap loop is refused ( $\alpha_x = \text{swap}(\alpha_y), \alpha_y = \alpha_x$  has no solution inside the marks). Mechanized: `z5_refutes_pinless` (the premise-only kit accepts a false conclusion) and `z5_no_pin` (the pin rows refuse the witness). Off the cycles no pin is needed — see the chaining lemma. An exact value is, however, the wrong general datum — the next remark generalizes the column and keeps this one as its degenerate species.

**Remark R80.3** (the carve column: pins generalized to predicates). An exact pin is measure-zero data: honest for a finite alphabet, unrepresentable for members whose wire states are continuous or infinite-dimensional. The column therefore generalizes: per zero-lag- cycle mark the producer supplies a *carve* — a predicate on the wire’s state carrier, presented as a scalar-codomain gate hypernet cited by digest (its nonnegativity locus the carve), or a plated aggregate gate where the member is a token-population system. The soundness question this raises is the design’s crux: a point composes trivially around an instant cycle (the joint assignment is the pin vector), while a carve leaves each delivery free within a set, so joint existence becomes a nonemptiness obligation over the carve product — the *diagonal*. Carve- invariance does not settle it: on the swap loop the carve rows hold at the maximal carve — the swap maps the mark set into itself (`z5_carvedDelivery_mark`) — yet *no* carve inside the marks closes the diagonal (`z5_no_carve_closure`): around the loop any jointly-admitted value is a swap fixpoint, and the only one lies outside the marks. So the carve rows come in three families: *containment* (carve refines mark), *carved delivery* (the rule’s own conditional-delivery judgment, cited at the carve events — the premises are literally the maximal-carve rows, `carvedDelivery_mark_iff_conditional`, so the column is one dial from the sketch’s judgments down to r4’s points), and one *diagonal certificate* per cycle, species-tagged: a witness point or bounded enumeration where states are finite (the degenerate species — and the swap loop is refused mechanically there); contraction rows with exact-rational cycle gain below one (Banach closes the diagonal — small-gain arithmetic reused at the  $\exists$ -face); convexity or order-interval flags (Kakutani, Tarski). The checker verifies only the species’ finite rows; each fixpoint theorem lives in the soundness metatheorem, per profile — exactly where Ionescu-Tulcea already lives for the stochastic assembly. Mechanized at this tier: the carved engine (`marks_of_carved_delivery`, the diagonal consumed abstractly as `CarveClosure`), the subsumption of pins as singleton carves (`marks_of_pinned_delivery_via_carve` — degeneracy as a theorem), the carve-level mutants (`z5_refutes_closureless`, `z1_refutes_walkless_carve`), and a fat-carve positive control in which no hypothesis names a value (`fatCarve_marks_realized`).

**Remark R80.4** (the reading of the premise, the properness presupposition, and W0: what breaks without each). Three further hypotheses earn their places by countermodels at the design tier. (i) Reading the component premise as co-realization (“some behaviour realizes assumptions and guarantee together”) is unsound: a component can co-realize only in a mode the closed loop never enters (a gate that cooperates only on inputs the wiring cannot produce), so the conditioning must do real work —  $\forall$ -conforming- $\exists$ -delivering is the reading under which the metatheorem is true. (ii) The properness presupposition on each premise’s conforming sub-body blocks vacuous conditioning: a component admitting no conforming input satisfies the conditional vacuously while delivering nothing. (iii) The W0-species rows block the empty composite (an inconsistent loop — a negation gate against a relay — satisfies every safety spec and no liveness spec), and for the liveness *construction* their tier discharge is stepwise: the composite must stay live at every stage given the schedule’s pins, because bare nonemptiness of the behaviour set is witnessed by runs the construction cannot use (a component may block after delivering; an instant subsystem’s solvability may flip on a pinned coordinate’s value). Stepwise properness is what the mechanized engine consumes.

**Lemma R80.5** (the assembly engine — soundness at the discrete-relational tier). *Fix  $n$  components over a wire alphabet, each with in-neighbours, a delivery lag ( $0 = \text{instantaneous}$ ), a memoryless admitted-output relation reading its lagged snapshot, and an initial segment. Suppose: (a) seriality (initial sets and output relations nonempty — the mechanism-presentation obligation of the latency rows); (b) a feasible schedule; (c) pins with their membership and pointed-delivery rows; (d) schedule-relative instant closure (at every stage, with pinned instantaneous coordinates held at their pins and pipelined coordinates at any given values, the remaining instantaneous coordinates close jointly). Then some joint run realizes every mark at its label.*

*Proof* (as mechanized, `marks_of_pinned_delivery`). *Build the run by stage recursion. At stage  $k$ , pipelined coordinates choose: their initial value before the pipe fills; the pin at their own label (legal because  $t_i \geq \text{lag}_i$  is a walk row); any admitted output otherwise (seriality). Instantaneous coordinates close jointly by (d), with the schedule’s pinned ones held at their pins. Two facts discharge the pinned constraints. First, the pin invariant: at its label every coordinate carries its pin — by construction for pipelined coordinates, by (d)’s base clause for instantaneous ones. Second, the walk’s alignment: for a marked component  $i$ , every in-neighbour  $j$  satisfies  $t_i = t_j + \text{lag}_i$ , so the snapshot  $i$  reads at delivery time is taken at stage  $t_j$  — where, by the invariant,  $j$  carries its pin. The pointed-delivery row therefore applies verbatim and admits the pin. Extension past the last label is seriality plus (d) at unpinned stages. The realized-at-label conclusion is the invariant plus the membership rows. Carved form (as mechanized, `marks_of_carved_delivery`): the same recursion with the invariant weakened from “carries its pin” to “lands inside its carve” — pipelined labeled coordinates now choose from the intersection of their admitted set with their carve (nonempty by the carved-delivery row, since the walk aligns their in-neighbours at labels where the invariant holds), and instantaneous labeled coordinates close through the diagonal certificate, in-carve and admitted at once. The pinned statement above is re-derived from the carved engine at singleton carves (`marks_of_pinned_delivery_via_carve`).*

**Lemma R80.6** (the chaining bridge — no pins where no cycle bites). *On a network whose dependency graph admits a topological order, the conditional-delivery premises alone produce pins satisfying the rows of Lemma R80.5: choose each component’s delivered value by its*

*premise, applied to the already-chosen deliveries of its in-neighbours, in topological order; dep-locality (a component reads only its declared in-neighbours) turns the chosen witness into the pointed row. Moreover acyclicity dissolves the joint instant solve: seriality alone furnishes the instant closure, coordinate by coordinate in order. Hence the premise-shaped rule with no value column is sound on acyclic-instant networks (`marks_of_conditional_delivery_acyclic`) — the pins are producer-derivable search data there, entering the wire only where the walk's own arithmetic says a cycle closed. Proof (as mechanized, `pins_of_conditional_delivery` + `instantClosure_of_acyclic`). Induction on topological levels: at each level, apply the premise at the snapshot assembling the lower levels' pins (conforming by their membership conjuncts); transport the chosen admission along dep-locality to every dep-agreeing snapshot. The instant closure by the same induction, with seriality supplying unpinned choices. The bridge holds at the dial's other end too: the same premises are the maximal-carve rows, and acyclicity dissolves the diagonal at any delivery-closed carve (`carveClosure_of_acyclic`), so the carved engine also concludes with nothing pinned and nothing carved on the wire (`marks_acyclic_via_maximal_carve`).*

*Remark R80.7 (the metatheorem beyond this tier).* The joint object lives in the soundness proof and only there: at the discrete-relational tier it is the recursion above; at stochastic tiers the joint law is assembled by Ionescu–Tulcea/Kolmogorov extension along the wiring's stagewise dependency structure, with the mark-escaping resolutions selected per the premises; for PDE profiles, whatever solution object the profile's semantic theorem provides. The rule's premise kit does not change per profile — only the bridge lemmas do, exactly as in the acyclic rule's grid. Those instances, the per-species diagonal devices at continuous tiers (Banach for the contraction species, Kakutani/Brouwer for the convex, Knaster–Tarski for the order-theoretic — each converting its species' finite rows into the joint instant solve the carved engine consumes abstractly), history-dependent mechanisms, and the general difference-constraint walk (windows, rational stages) are open; the mechanized tier is the one this section proves, and the conditional mark warrants exactly it. Two scope fences are part of the statement: marks are single-dip graded-reach demands (finitely realizable, extension-persistent) — recurrence-shaped liveness stays outside; and the rule trades completeness for finite presentation — a component delivering only on its favourite conforming input can witness a joint behaviour no conditional-delivery premise certifies.

## Rule 81. QSIMTRANSPORT (core rule)

### The rule (Steele metanotation)

as realized in the mechanized development; source row: `QTSL-rules.toml` — *QSimTransport*. The metanotation statement is typeset by hand for notational quality; its mechanized ground truth is the Lean statement below, extracted from the sources at every build of this book and hash-bound. The rule *roster* is machine-checked (every mechanized rule tag round-trips to exactly one catalogue row); the statement *text* is editorial, checked by eye against the extracted Lean beside it.

$$\frac{S' \models \text{spec}' \quad \text{QSim}(\sigma, S, S')}{S \models \sigma^* \text{spec}'} \text{QSIMTRANSPORT}$$

certification transport along a coarse-graining:  $\sigma$  is an exact simulation witness,  $S'$  coarse-grains  $S$  — if  $S'$  is certified and  $\text{QSim}(\sigma, S, S')$  holds ( $\sigma$  maps every behaviour of  $S$  to a behaviour of  $S'$ ), then  $S$  is certified for the pulled-back spec ( $\sigma^*$  pulls back the whole interface spec, assumptions and guarantees). Expectation specs pull back with the bound intact; region/invariance specs pull back to the preimage region. The former side condition (per-mode polynomial map + compatibility squares as BL leaves) is the kind's discharge, one node down: *QSIMDISCHARGE* consumes exactly those squares ( $\sigma$ -strict tier; the kernel tier joins with its own bounded coverage walk), *QSIMCOMPOSE* composes witnesses. Exactness is what *QSim* asserts — the approximate  $\sigma$ - $\varepsilon$  class concludes *QDist*, never this premise. One-sided functional refinement — a simulation witness is never a two-sided coupling, satisfaction of an interface-bearing spec is plain *QSat*, as at *QWIRECOMPOSE*.

*QSIMTRANSPORT* transports certification along a coarse-graining: if the abstract system  $S'$  is certified, and the simulation judgment  $\text{QSim}(\sigma, S, S')$  holds — its discharge, one node down, checks the per-mode polynomial map's compatibility squares as inherited BL leaves — then the concrete system  $S$  is certified for the pulled-back spec  $\sigma^* \text{spec}'$ . A producer uses it in the direction the rule states: certify the abstraction *once* (small state space, cheap rows), then reuse that certificate under every refinement that simulates it, paying only the simulation judgment's discharge per refinement.

What the cited theorems warrant is three strata. The *behavioural* form: over compiled behaviour classes, if  $\sigma$  maps every behaviour of  $S$  to a behaviour of  $S'$  (the semantic content of the squares) and  $S'$ 's behaviours all satisfy the spec, then  $S$ 's behaviours satisfy the pullback — two lines, which is the honest size of the rule's semantic content; everything substantive in an application is the sequent-level discharge of the squares. The *finite-kernel* instance, where the development has machine-checked simulation machinery: a functional simulation witness at the finite Markov tier is exactly a pushforward-kernel identity (per state, the pushed concrete kernel row equals the abstract kernel row at the image state), the marginal-process lemma then transports laws at every time, and both spec-transport faces follow — expectation specs pull back along  $\sigma$  with the bound intact, and region/invariance specs pull back to the preimage region. And the *general measurable-kernel* tier, mirroring the finite instance name-for-name over Markov kernels and the Giry monad: the same pushforward identity (now a *Measure.map* equation per state), the same law transport at every horizon, both spec-transport faces — with the finite tier's nonnegativity hypotheses gone, true by type.

The witness is one-sided by design: a simulation map is functional refinement, not a two-sided relational coupling. A functional simulation induces a degenerate coupling, but the transport theorems never route through it — they are the pushforward identity plus summation identities, and the relational tier's coupling machinery (joint kernels, absorption hypotheses) is deliberately not shared. What breaks without the hypotheses: without the compatibility squares the pushed law and the abstract law decouple at the first step, and the pullback claims anything; without the nonnegativity hypotheses of the region form, signed “mass” could cancel and hide probability outside the preimage region.

**notes** The general measurable-kernel tier is discharged (third stratum, bound below). The simulation premise is the judgment kind *QSim*, baked in the extension theory together with its discharge and composition nodes: the former side condition (map data + compatibility squares) is that kind's discharge, so nothing here renders as a hypothesis mark. Exactness is what the kind asserts — the approximate class concludes distance judgments instead. What remains beyond the three proven strata: the categorical strengthening under which the composition rule could cite the lens-composition theorem as a lemma *template* rather than proving its cells directly — the direct proofs never pull back along strict weakenings, which is why the strengthening is not a dependency of anything on this page. No end-to-end certificate exercises the rule yet. Related reading, not dependency: an exchangeability quotient is a simulation map, so aggregate-space reduction can be *read* as an instance of this rule — it stands on its own proof.

## Correspondence (Steele display ↔ Lean)

reviewer-certified against the displayed texts

The dictionary below is a reviewer-certified statement of how the mechanized statements above interpret the displayed rule: display metavariable  $\mapsto$  Lean binder, each display hypothesis  $\mapsto$  the premise or side condition carrying it, the display conclusion  $\mapsto$  the goal — with any deliberate difference in width between display and mechanization named outright. Certification is recorded as a hash triple over (the displayed cell, the extracted statement texts, this dictionary's own text); if any of the three changes, this block turns amber until a reviewer re-certifies. The correspondence claim itself remains editorial — reviewer-grade, not machine-checked; its machine-checked successor types each soundness statement against the rule as a structured object, and supersedes this block per rule as it lands.

Three strata, as the commentary's conditional scope states; the display maps onto each at its own granularity. *Behavioural*: the displayed conclusion  $S \models \sigma^* \text{spec}' \mapsto \text{pullback's goal } \text{Beh} \subseteq \sigma^{-1} \text{spec}'$  over compiled behaviour classes; the E1 premise  $S' \models \text{spec}' \mapsto \text{hsat} : \text{Beh}' \subseteq \text{spec}'$ ; the judgment premise  $\text{QSim}(\sigma, S, S') \mapsto \text{hsim} : \sigma^{-1} \text{Beh} \subseteq \text{Beh}'$  — the kind's *semantic content* exactly: the per-mode polynomial structure of  $\sigma$  is erased ( $\sigma$  is any function), and the BL discharge of the compatibility squares lives in the kind's own discharge node, outside this bound set. The statement is axiom-free set algebra — two lines, the honest size of the rule's semantic content.

- *finite-kernel instance*: the simulation witness  $\mapsto \text{PushKernel } \sigma K Q$  — the per-state marginal identity  $\text{push } \sigma (K s) = Q (\sigma s)$ , which is what a functional simulation IS at this tier.
- expectation specs pull back “with the bound intact”  $\mapsto \text{sim\_expect}$ , and the certified statement is *stronger* than the display's reading: an *equality* of expectations at every horizon ( $\sum s, \text{law } K \mu_0 n s * g (\sigma s) = \sum b, \text{law } Q (\text{push } \sigma \mu_0) n b * g b$ ), with  $\text{sim\_expect\_bound}$  the displayed inequality direction as its corollary (certify the abstraction once, reuse under refinement).
- region/invariance specs pull back to the preimage  $\mapsto \text{sim\_region}$ : abstract law puts no mass outside  $R' \Rightarrow$  concrete law puts none outside  $\sigma^{-1} R'$  — and this face alone consumes nonnegativity ( $hK, h\mu_0$ ): the commentary's “signed mass could cancel” hypothesis, visible as exactly two binder rows.
- $\text{expect\_push}$  is the observable-pullback engine ( $\sigma^*$  at expectation granularity), fibre-summation algebra.

*Measurable-kernel tier* (second bound block, module `SimTransportMeas`, namespace `...QtslCompose.Meas`): the simulation witness  $\mapsto \text{Meas.PushKernel } \sigma K Q$  — per state,  $(K s). \text{map } \sigma = Q (\sigma s)$  over `ProbabilityTheory.Kernels`;  $\text{push\_law}$  is the law transport at every horizon over the  $n$ -fold `Giry` bind;  $\text{sim\_expect\_bound}$  and  $\text{sim\_region}$  are the two spec-transport faces in measure vocabulary (the addressability equalities  $\text{sim\_expect\_lintegral\_integral}$  live in the module, cited not bound); and  $\text{pushKernel\_iff\_comp}$  is the intertwining square —  $\text{Kernel.deterministic } \sigma h\sigma \circ_K K = Q \circ_K \text{Kernel.deterministic } \sigma h\sigma$ , push-after-step equals step-after-push — the shape the lens/fibred strengthening would functor over, so that residue names a bound *object*, not a blank. The finite tier's nonnegativity binders ( $hK, h\mu_0$ ) vanish at this tier by type, which is the “signed mass could cancel” clause discharged by construction. Width note: one-sidedness is structural in the bound statements — nothing consumes or constructs a joint kernel;  $\text{push\_law}$  (the shared marginal-process lemma) is genuinely the same lemma the relational tier rides, at both tiers, while the coupling machinery is deliberately absent from this bound set. The conditional mark is dropped: the former side condition is the baked `QSim` premise; what remains named — the lex/fibred (categorical) strengthening — is a dependency of nothing on this page.

## Lean verifier receipts

module BernsteinLogicAux.QtslCompose.SimTransport; bound build b2a09651f9a0... (bound from receipt dc0250279a3a2d0d, 2026-07-19T18:24:55Z). A receipt records that named checking layers accepted a build: (module, compiled-artifact SHA-256, environment SHA-256, checker layers), minted when the checking gate ran; the store receipts attesting the bound build are listed with the layers each run credited. Nothing here asks the reader to trust the store: every layer is an independently runnable program over the quoted sources — rebuild the module and re-run the checkers to reproduce the verdict. Receipts attesting superseded builds credit no layer and are omitted from this rendering (the count of omissions, if any, is noted below).

### gate-layer coverage of the bound build:

build (lake build (elaboration)) current

replay (leanchecker (official kernel replay)) current

hardened (safe\_verify (hardened screen)) current

decorrelated (lean4export + nanoda (decorrelated kernel)) current

comparator: none no fixture in the three-implementation comparator harness (compiled / kernel-interpreted / reference-interpreted) exercises this rule.

## HOL4 statement

### NO HOL STATEMENT YET

The satisfaction-judgment extension postdates the HOL4 port entirely: the ported cone is the base calculus's check-function surface (theory bern\_catalogue), and no extension-theory definition — nothing shaped like simulation transport — exists in the HOL development. The box waits on a HOL port of the satisfaction stratum, which is its own campaign.

## HOL verifier receipts

**NONE**

no HOL verification receipt exists for this rule.

## Proof

Genre: core rule (tier 1). The rule’s semantic content is honestly small — the behavioural pullback is two lines — and the section says so rather than inflating it; the substance of any application is the sequent-level discharge of the compatibility squares, plus the finite-kernel instance where the transport is proven against actual chain machinery. The strata beyond the two walked here, and the genuine gaps, are marked loudly.

**Setting and claim.** A simulation witness  $\sigma : S \rightarrow S'$  is a per-mode polynomial map whose *compatibility squares* — commutation of  $\sigma$  with the two systems’ dynamics declarations, mode by mode — are checked as inherited sequent leaves; the rule consumes the witness as the judgment  $\text{QSim}(\sigma, S, S')$ , whose own discharge node carries those squares. The rule: from  $S' \models \text{spec}'$  and the judgment, conclude  $S \models \sigma^* \text{spec}'$  — certify the abstraction once, reuse under refinement [37, 168].

**Theorem R81.1** (behavioral pullback). *Let  $\text{Beh}$ ,  $\text{Beh}'$  be the compiled behaviour classes of  $S$ ,  $S'$ , and suppose  $\sigma$  maps behaviours to behaviours ( $\sigma[\text{Beh}] \subseteq \text{Beh}'$  — the semantic content of the compatibility squares). If every behaviour of  $S'$  satisfies  $\text{spec}'$ , then every behaviour of  $S$  satisfies  $\sigma^{-1}[\text{spec}']$ .*

*Proof.*  $\omega \in \text{Beh}$  gives  $\sigma(\omega) \in \text{Beh}' \subseteq \text{spec}'$ , i.e.  $\omega \in \sigma^{-1}[\text{spec}']$  (pullback). Two lines is the honest size: the rule’s semantic content is inclusion-chasing, and everything substantive in an application is establishing  $\sigma[\text{Beh}] \subseteq \text{Beh}'$  from the checked squares — per-mode polynomial identities, discharged by the base calculus. The hypothesis is not droppable to “ $\sigma$  is any map”: without the squares the image of a concrete behaviour need not be an abstract behaviour, and the pullback claims anything at all.  $\square$

**The finite-kernel instance.** At the finite Markov tier the witness has teeth the behavioural form leaves abstract: a *functional simulation* is per-state marginal identity — pushing the concrete kernel row at  $s$  along  $\sigma$  yields the abstract kernel row at  $\sigma(s)$  (a pushforward-kernel witness) — and the transport theorems are proven against the chain machinery.

**Lemma R81.2** (observable pullback). *For any law  $\mu$  on the concrete states and observable  $g$  on the abstract states,  $\sum_b (\sigma_* \mu)(b) g(b) = \sum_s \mu(s) g(\sigma(s))$ ; and along a pushforward-kernel witness, the time- $n$  expectation of a pulled-back observable on the concrete chain equals the abstract chain’s expectation of  $g$  at time  $n$  (started from the pushed initial law). Hence any certified expectation bound proven against the abstract chain holds for the concrete chain at the pulled-back observable.*

*Proof.* The first identity is summation over fibres of  $\sigma$  (expect\_push). The second composes it with the marginal-process lemma — the per-state marginal identities propagate, by induction on time, to equality of pushed laws at every time — giving sim\_expect; the bound transports by rewriting (sim\_expect\_bound). Note the direction: the producer proves one bound on the small chain and every refinement inherits it; nothing is re-proven per refinement beyond the witness identities themselves. The interface reading rides the same equalities: an assumption event  $A'$  pulls back with its mass intact (the pushed law at time  $n$  equals the abstract law, so  $\nu_n(\sigma^{-1} A') = \lambda_n(A')$ ), hence assumption-weighted bounds transport, and conditional expectations transport whenever the conditioning mass is positive.  $\square$

**Lemma R81.3** (region pullback). *Along a pushforward-kernel witness with entrywise-nonnegative kernel and initial law: if the abstract law at time  $n$  puts no mass outside  $R'$ , the concrete law at time  $n$  puts no mass outside  $\sigma^{-1}[R']$ .*

*Proof.* For  $s$  with  $\sigma(s) \notin R'$ : the concrete mass at  $s$  is at most the pushed mass at  $\sigma(s)$  (one nonnegative term of a fibre sum), which equals the abstract mass at  $\sigma(s)$  (the marginal-process lemma), which is zero; nonnegativity closes the squeeze (sim\_region). The nonnegativity hypotheses are load-bearing, not hygiene: with signed “mass” the fibre sum could cancel — a negative sibling hiding positive mass at  $s$  outside the preimage region — and the single-term bound fails. Nonnegativity is what makes “no mass outside  $R'$ ” transfer pointwise through a many-to-one map.  $\square$

**Remark R81.4** (refinement is one-sided; a simulation is not a coupling). The witness machinery genuinely shared with the relational (two-chain) tier is exactly the pushforward-kernel identity and the marginal-process lemma — a functional simulation *is* such a witness. Nothing else transfers: the relational tier’s certificates are joint-kernel data over a product space with absorption and drift hypotheses, and none of that is simulation transport. A functional simulation induces a degenerate coupling, but the theorems above never route through it — they are pushforward plus summation identities, full stop. Conflating the two would import hypotheses (coupling emptiness, absorption) that this rule neither needs nor checks.

**Remark R81.5** (the gaps, loud). The section walks two strata — behavioural, and finite-kernel. The general measurable-kernel tier is mechanized and bound in this rule’s entry, mirroring the finite instance name-for-name over Markov kernels (the same pushforward identity per state, now a Measure.map equation; law transport at every horizon; both spec-transport faces — with the finite tier’s nonnegativity hypotheses gone, true by type); it is cited there rather than re-walked here. Not yet mechanized: the categorical strengthening under which the composition rule could cite the lens-composition theorem of [37] as a lemma *template* — the direct composition proofs never pull back along strict weakenings, so nothing in this book depends on that strengthening; it is named so that its absence is a recorded choice, not an oversight. The judgment kinds the rule consumes and concludes into are staged in the certificate schema (the simulation judgment together with its discharge and composition nodes), but no end-to-end certificate yet exercises the rule — loader and end-to-end work, not mathematics. Related reading, not dependency: an exchangeability quotient is a simulation map, so aggregate-space reduction can be *read* as an instance of this rule; it stands on its own proof and cites nothing here.

## Rule 82. QFLATTEN (admissible rule)

### The rule (Steele metanotation)

as realized in the mechanized development; source row: QTSL-rules.toml — *QFlatten*. The metanotation statement is typeset by hand for notational quality; its mechanized ground truth is the Lean statement below, extracted from the sources at every build of this book and hash-bound. The rule *roster* is machine-checked (every mechanized rule tag round-trips to exactly one catalogue row); the statement *text* is editorial, checked by eye against the extracted Lean beside it.

$$\frac{\text{QFlatEq}(\text{sys}, \text{flat}) \quad \mathcal{M}_{\text{flat}}, x_0 \in R \models \varphi \text{ (the closed-system pipeline's judgment)}}{\text{sys}, x_0 \in R \models \varphi} \text{QFLATTEN}$$

*flat* is the flattening of the composite *sys*; the substitution rule it always was: satisfaction transports across the flattening equation. The former side condition (polynomial substitution + guard-product bookkeeping) is the kind's discharge — oracle-shaped by construction (*qtsl\_flatten*, a bounded deterministic recompute over declaration structure), with the refusal boundary stated positively as the judgment's scope: shared-carrier confinement, and binary wiring with *n*-ary/directed cases reducing by currying = the checker's substitution recompute (refusal-shaped completeness cost, never a soundness hypothesis). The guarantee the rule was minted to state — SysWire adds structure, never expressiveness — is carried by the kind's existence: the flattened manifest's compiled semantics is the composite's (theorem at both kernel tiers on the synchronous-product face), and the projections remain free QSIMTRANSPORT witnesses under sibling well-formedness (unit row sums). The clock rows (schedule hypotheses, simultaneity, non-Zeno) are premise classes cited by every composition rule, deliberately not rows here.

QFLATTEN transports satisfaction across the flattening equation: given the judgment *QFlatEq*(*sys*, *flat*) — *flat* is the flattening of the composite presentation, discharged by the checker's substitution recompute — a verdict on the monolithic manifest is a verdict on the composite. A producer reaches for it as the bridge to every closed-system pipeline: compile nodes, certificate synthesis, and the whole battery machinery operate on one flat manifest, while modelling happens compositionally. The rule's two guarantees pull in opposite directions and are both load-bearing: wiring adds *structure*, never *expressiveness*. Never expressiveness: the flattened manifest's compiled semantics is exactly the composite's — at the compiled class this is definitional (a presentation's semantics IS its flattened object's), and at the finite-kernel tier it is a theorem: the monolithic chain's law is, at every horizon, the product of the component laws. Added structure: the flattened manifest remembers its components — the projections are exact simulation witnesses for free, so every component-level specification remains addressable on the flattened object through QSIMTRANSPORT.

What the judgment's discharge recomputes: the substitution itself — polynomial substitution plus guard-product bookkeeping — which is why the rule is admissible rather than core: it discharges against verified recomputation and the semantic witness pair, adding no new kernel content. Directed substitution wirings do *not* reduce to the independent synchronous product of the witness pair — wiring an upstream output into a downstream input creates conditional dependence the product law does not carry; they rest on the checker's substitution recompute itself (currying the upstream trajectory into a dependent downstream kernel), definitional in the compiled class.

What would break: component well-formedness (unit row sums) is what makes the projections exact witnesses — against a defective second factor, the first projection's pushed row picks up the leftover mass as a spurious scale factor, and the component-spec addressability claim fails. The scheduling hypotheses (clock rows, simultaneity, non-Zeno families) are deliberately premise classes cited by every composition rule rather than rows of this one.

**notes** The flattening premise is the judgment kind *QFlatEq*, baked in the extension theory; its discharge is the flatten recompute behind a registry seam, with the shared-carrier and binary-wiring confinements as the judgment's stated scope — refusal-shaped, never a hypothesis of this rule. The proven fragment spans two tiers: the finite-kernel tier, on the same substrate as the relational chain machinery — the tier where “law”, “product”, and “pushforward” are finite object-arithmetic objects — and the general measurable-kernel tier, where they are the Giry-monad objects (second bound block). The remaining confinement is the *independent binary product* witness pair — a design fence, not a gap: *n*-ary independent wirings iterate it, while directed wirings rest on the checker's substitution recompute (a dependent downstream kernel, not the independent product). The general compiled-class statement is substitution correctness, checker recomputation by design.

```

BernsteinLogicAux.QtslCompose.FlattenMeas . **bind\_parallelComp**

statement bound

```

/-- One step of the flattened (synchronous-product) chain factors as the
product of the component steps. (The measurable-tier face of
`step_prodKernel`.) Proof is pure ` $\circ_m$ `-algebra:
`Measure.prod_comp_right`/`prod_comp_left` are the two one-sided
measure-level product-bind identities, fused by
`Kernel.parallelComp_comp_parallelComp`. -/
theorem bind_parallelComp ( $\mu$  : Measure  $\alpha$ ) ( $\nu$  : Measure  $\beta$ )
  (K : Kernel  $\alpha$   $\alpha$ ) (Q : Kernel  $\beta$   $\beta$ )
  [SFinite  $\mu$ ] [SFinite  $\nu$ ] [IsSFiniteKernel K] [IsSFiniteKernel Q] :
  ( $\mu$ .prod  $\nu$ ).bind (K  $\mathbb{I}_k$  Q) = ( $\mu$ .bind K).prod ( $\nu$ .bind Q)

```

## Correspondence (Steele display $\leftrightarrow$ Lean)

**reviewer-certified against the displayed texts** The dictionary below is a reviewer-certified statement of how the mechanized statements above interpret the displayed rule: display metavariable  $\mapsto$  Lean binder, each display hypothesis  $\mapsto$  the premise or side condition carrying it, the display conclusion  $\mapsto$  the goal — with any deliberate difference in width between display and mechanization named outright. Certification is recorded as a hash triple over (the displayed cell, the extracted statement texts, this dictionary's own text); if any of the three changes, this block turns amber until a reviewer re-certifies. The correspondence claim itself remains editorial — reviewer-grade, not machine-checked; its machine-checked successor types each soundness statement against the rule as a structured object, and supersedes this block per rule as it lands.

The displayed judgment premise  $\mathbf{QFlatEq}(\text{sys}, \text{flat})$  — the flattened manifest has the *same* compiled semantics, each projection  $\pi_i$  a free  $\mathbf{QSIMTRANSPORT}$  witness —  $\mapsto$  the theorem pair at the finite-kernel tier:  $\text{law\_prodKernel}$  (never expressiveness) and  $\text{pushKernel\_fst}/\text{snd}$  (added structure). The kind's discharge (the substitution recompute) has *no* Lean counterpart by design: at the compiled class the presentation's semantics IS its flattened object's, so that discharge is checker recomputation, and what is theorem-shaped is exactly what is bound. The rule's own transport step (a verdict on  $\mathcal{M}_{\text{flat}}$  is a verdict on  $\text{sys}$ ) is substitution of equals along the judgment — no separate statement to bind.

- $\text{SysWire}(w, \text{Sys}_1, \dots, \text{Sys}_n) \mapsto$  the *binary synchronous product*: kernels  $K_1 : \alpha \rightarrow \alpha \rightarrow \mathbb{R}$ ,  $K_2 : \beta \rightarrow \beta \rightarrow \mathbb{R}$  over finite types, flattened as  $\text{prodKernel}$  on  $\alpha \times \beta$ . Two confinements at this block, both design fences: binary-independent (directed and  $n$ -ary substitution wirings rest on the checker's substitution recompute — currying the upstream trajectory into a *dependent* downstream kernel, which is not the independent product bound here; per the module header), and finite-kernel tier ( $[\text{FIntype } \alpha] [\text{FIntype } \beta]$ ) — the latter discharged by the measurable-tier block below, leaving the independent binary product as this bound set's remaining confinement.
- same compiled semantics  $\mapsto$   $\text{law\_prodKernel}$ :  $\text{law} (\text{prodKernel } K_1 K_2) (\text{prodDist } \mu_1 \mu_2) n = \text{prodDist} (\text{law } K_1 \mu_1 n) (\text{law } K_2 \mu_2 n)$  at every  $n$  — and its binder row is the width fact: the identity is proven for *arbitrary* kernel and law data, no Markov/distribution well-formedness consumed — pure bilinear algebra, strictly wider than the display's well-formed-system reading, safe direction.
- projections as free  $\mathbf{QSIMTRANSPORT}$  witnesses  $\mapsto$   $\text{pushKernel\_fst} : \text{PushKernel Prod.fst} (\text{prodKernel } K_1 K_2) K_1$  — consuming only  $\forall b, \sum b', K_2 b b' = 1$ : the *sibling* component's unit row sums, nothing of its own, and not even nonnegativity — the certified statement isolates exactly which well-formedness fragment the commentary's “what would break” paragraph names (a defective second factor leaks scale into the pushed row).  $\text{snd}$  mirrors.  $[\text{DecidableEq}]$  binders enter only here (the pushforward's fibre sums).

*Measurable-kernel tier* (second bound block, module FlattenMeas, namespace  $\dots\text{QtslCompose.Meas}$ ): the product is mathlib's own pair —  $K \mathbb{I}_k Q$  ( $\text{Kernel.parallelComp}$ ) over  $\text{Measure.prod}$  — and the theorem pair transposes name-for-name:  $\text{law\_parallelComp}$  (never expressiveness:  $\text{law} (K \mathbb{I}_k Q) (\mu.\text{prod } \nu) n = (\text{law } K \mu n).\text{prod} (\text{law } Q \nu n)$  at every horizon, over  $\text{SimTransportMeas}'s$

Giry-bind law) and `pushKernel_fst/_snd` (added structure: projections as `Meas.PushKernel` witnesses), with `bind_parallelComp` the one-step glue. Binder floor, the honest analogue of the finite tier's “arbitrary data” width fact: `SFinite/IsSFiniteKernel` — product-measure theory is s-finite theory — still strictly wider than the display's Markov/probability reading, same safe direction. And the “what would break” margin-zero witness is displayed by `mathlib` itself: `Measure.map_fst_prod` gives the pushed row as  $(\nu \text{ univ}) \cdot \mu$  — leak coefficient the sibling's total mass — with `pushKernel_fst` consuming exactly `[IsMarkovKernel Q]` and nothing of `K`'s own well-formedness, not even finiteness. Width note: the clock rows (schedule/simultaneity/non-Zeno) are premise classes deliberately absent from both display and bound statements; the closure facts at both tiers live in their modules but outside this bound set — cited, not certified here: `finite isMarkov_prodKernel`, `isDist_prodDist`, `push_fst_prodDist`; measurable `sfinite_law`, `isProbabilityMeasure_law`, the addressability compositions `sim_expect_fst/_snd` (component specs consumed end-to-end through `QSIMTRANSPORT`'s measurable engine), the bridge `pushKernel_iff_stochSim`, and the `mathlib` instances `IsMarkovKernel (K  $\mathbb{K}$  Q)` / `prod.instIsProbabilityMeasure`.

## Lean verifier receipts

module `BernsteinLogicAux.QtslCompose.Flatten`; bound build `30ed43793772...` (bound from receipt `8cd9a31cf76c1595`, 2026-07-19T18:24:49Z). A receipt records that named checking layers accepted a build: (module, compiled-artifact SHA-256, environment SHA-256, checker layers), minted when the checking gate ran; the store receipts attesting the bound build are listed with the layers each run credited. Nothing here asks the reader to trust the store: every layer is an independently runnable program over the quoted sources — rebuild the module and re-run the checkers to reproduce the verdict. Receipts attesting superseded builds credit no layer and are omitted from this rendering (the count of omissions, if any, is noted below).

hardened (safe\_verify (hardened screen)) current

decorrelated (lean4export + nanoda (decorrelated kernel)) current

comparator: none no fixture in the three-implementation comparator harness (compiled / kernel-interpreted / reference-interpreted) exercises this rule.

## HOL4 statement

### NO HOL STATEMENT YET

The HOL4 development checks the base calculus's wire format (theory `bern_catalogue`). QFLATTEN operates on system presentations of the extension theory — baked, System stratum and all; its semantic witnesses live in the auxiliary Lean package. No HOL development consumes the extension theory's rows; the box becomes writable when a flatten recompute joins a ported checker chain.

## HOL verifier receipts

### NONE

no HOL verification receipt exists for this rule.

## Proof

Genre: admissible rule (tier 2) — a proof-tree-rewriting recipe of the reduction-to-verified-machinery kind: the node discharges against the checker's substitution recompute plus a semantic witness pair, not against catalogue nodes. Scope, stated loudly: the witness pair is proven at the finite-kernel tier, on the synchronous-product wiring; the general compiled-class statement is substitution correctness, definitional by the presentation semantics.

**Recipe R82.1** (the QFLATTEN rewrite). A QFLATTEN node transports satisfaction across the flattening judgment — *flat* the monolithic manifest of a composite presentation:

$$\frac{\text{QFlatEq}(\text{sys}, \text{flat}) \quad \mathcal{M}_{\text{flat}}, x_0 \in R \models \varphi}{\text{sys}, x_0 \in R \models \varphi} \text{QFLATTEN} \quad \text{the checker replays the substitution.}$$

The rewrite target contains zero catalogue nodes: a presentation's compiled semantics *is* its flattened object's, so at the compiled class the judgment's discharge is a recomputation — polynomial substitution plus guard-product bookkeeping — and the rule adds no kernel semantic content (the admissibility criterion). What deserves proof, and gets it below, is the slogan the rule is trusted for: **wiring adds structure, never expressiveness**. Directed substitution wirings do *not* reduce to the independent synchronous product treated below — wiring an upstream output into a downstream input creates conditional dependence the product law does not carry — so the flatten witness below attests the independent-product case, and the directed case rests on the substitution recompute (the judgment's discharge above) alone.

**Proposition R82.2** (never expressiveness: the flatten witness). *Let  $K_1, K_2$  be finite kernels with initial laws  $\mu_1, \mu_2$ , and let the flattened manifest be the product kernel  $K_{\otimes}((a, b), (a', b')) = K_1(a, a') K_2(b, b')$  with initial law  $(\mu_1 \otimes \mu_2)(a, b) = \mu_1(a) \mu_2(b)$ . Then at every horizon  $n$ ,*

$$\text{law}_{K_{\otimes}}(\mu_1 \otimes \mu_2, n) = \text{law}_{K_1}(\mu_1, n) \otimes \text{law}_{K_2}(\mu_2, n) :$$

*the monolithic chain's law is, at every time, exactly the product of the component laws — the composite presentation and its flattened manifest compile to the same semantics.*

*Proof.* One step factors, by Fubini for finite sums and bilinearity:

$$\text{step}_{K_{\otimes}}(\mu_1 \otimes \mu_2)(a', b') = \sum_{a, b} \mu_1(a) \mu_2(b) K_1(a, a') K_2(b, b') = \left( \sum_a \mu_1(a) K_1(a, a') \right) \left( \sum_b \mu_2(b) K_2(b, b') \right),$$

i.e.  $\text{step}_{K_{\otimes}}(\mu_1 \otimes \mu_2) = \text{step}_{K_1} \mu_1 \otimes \text{step}_{K_2} \mu_2$ . Induction on  $n$  closes. Closure rides along: the product of kernels is a kernel and the product of laws is a law (nonnegativity termwise; unit masses by the same bilinear factorization —  $\sum_{a, b} \mu_1(a) \mu_2(b) = 1 \cdot 1$  for the product law,  $\sum_{a', b'} K_1(a, a') K_2(b, b') = 1 \cdot 1$  per product row).  $\square$

**Proposition R82.3** (added structure: the projections are free simulation witnesses). *If  $K_2$  is row-stochastic, the first projection is an exact intertwining witness from  $K_{\otimes}$  onto  $K_1$ :  $\pi_{1\#} K_{\otimes}((a, b), \cdot) = K_1(a, \cdot)$  for every product state  $(a, b)$ ; symmetrically for  $\pi_2$  under row-stochastic  $K_1$ ; and  $\pi_{1\#}(\mu_1 \otimes \mu_2) = \mu_1$  whenever  $\mu_2$  has unit mass.*

*Proof.*  $\pi_{1\#} K_{\otimes}((a, b), \cdot)(a') = \sum_{b'} K_1(a, a') K_2(b, b') = K_1(a, a') \sum_{b'} K_2(b, b') = K_1(a, a')$ , the last step by the unit row sum. The initial-law statement is the same computation at  $\mu$ . Consequence: the flattened manifest *remembers* its components — each projection is a free exact-intertwining (PushKernel) witness, the QSIMTRANSPORT witness form, instantiating the strict (zero-degradation) column of the QDISTTRANSPORT matrix — so every component-level specification remains addressable on the flattened object with zero degradation. SysWire adds these handles and nothing else: Proposition R82.2 caps expressiveness, this proposition delivers the structure.  $\square$

**Remark R82.4** (why the well-formedness hypotheses are not decoration). Both directions consume them. In Proposition R82.3, drop the unit row sum of the *other* factor and the projection witness fails: the pushed row picks up  $\sum_{b'} K_2(b, b')$  as a spurious scale factor, so a sub-stochastic (leaky) second component would make every component-1 judgment transport against a deflated law — the component-spec addressability claim silently weakens. In Proposition R82.2, unit masses are what make the product law a probability law at every time. The scheduling hypotheses of composite dynamics — clock rows, simultaneity, non-Zeno families — are deliberately *premise classes* cited by every composition rule rather than rows of this one: flattening is about state and kernel structure, and importing the clock discipline here would duplicate its single authoritative statement.

*Remark* R82.5 (the tier boundary, honestly). The propositions above are the synchronous-product instance at the finite-kernel tier — the tier where law, product, and pushforward are finite exact-arithmetic objects, shared with the relational-chain machinery. General wirings (directed substitution, guard products) reduce by the checker’s own recompute; the reduction is definitional in the compiled class and is not re-proven as a theorem here. Nothing above claims the measure/kernel tier; its flatten-commutes statements — the same theorem pair over Markov kernels and product measures — are mechanized and bound in this rule’s entry, cited there rather than re-walked here.

## Rule 83. QLinGrowthDischarge (core rule)

### The rule (Steele metanotation)

as realized in the mechanized development; source row: QTSL-rules.toml — *QLinGrowthDischarge*. The metanotation statement is typeset by hand for notational quality; this rule cites no Lean statements yet (the absence is stated loudly below). The rule *roster* is machine-checked (every mechanized rule tag round-trips to exactly one catalogue row); the statement *text* is editorial.

$$\frac{\text{env}_i : B \vdash \pm f_i(x) \leq a + b \|x\|}{\models \text{QLinGrowth}(f, a, b, B)}$$

QLinGrowthDischarge concludes the linear-growth-envelope kind with the constants carried: membership of a polynomial vector field in the envelope  $(a, b)$  over a scope box, from per-coordinate affine-envelope sign sequents — exact-rational, checker-replayed. Downstream cells consume the pair  $(a, b)$  arithmetically, never a membership bit: the kind exists precisely so that growth constants compose.

**notes** Entered at the roster census (baked, never catalogued); no Lean statement binds it yet. The displayed norm form is schematic — the envelope rows' own sequent shape is the authority.

### Theory rows (geolog)

The rule's certificate content as it is declared in the geolog theory the checker loads — payload schema, side-condition demands, and axiom rows, quoted from the theory source at every build of this catalogue (a stale quotation cannot exist). Axiom modes: chase = the engine derives; report = a violation is a loud judgment; refuse = a violation gates admission. Side-condition relations are discharged by bounded evaluation at the engine's ground seam, never by derivation.

### Lean statement

**not yet mechanized** this rule cites no Lean statements: nothing on this page is hash-bound for it, and its dashboard row shows the same absence across the statement, receipt, and correspondence columns.

### HOL4 statement

#### NO HOL STATEMENT YET

No HOL development of the extension theory exists.

### HOL verifier receipts

#### NONE

no HOL verification receipt exists for this rule.

## Proof

Genre: core rule (tier 1), the discharge species. This section states the rule's soundness obligation exactly, per the catalogue's completeness-over-polish charter (a rule that can only be named-and-gapped is still a row); the discharge is open debt on the mechanization column, and the schema quoted in the entry is the baked ground truth.

**Soundness obligation.** The per-coordinate affine-envelope sign sequents on the scope box jointly certify membership of the field in the linear-growth envelope with constants  $(a, b)$ ; the kind carries the constants so that downstream consumers compose them arithmetically. The obligation is that the envelope rows' sequent semantics entail the envelope inequality coordinatewise on the scope box — a per-row sign-sequent instantiation.

*Remark* R83.1 (status). No Lean statement binds this node. The displayed norm form is schematic; the envelope rows' own sequent shape (exact-rational, checker-replayed) is the authority.

## Rule 84. QMARGINALCOMPAT (core rule)

### The rule (Steele metanotation)

as realized in the mechanized development; source row: QTSL-rules.toml — *QMarginalCompat*. The metanotation statement is typeset by hand for notational quality; this rule cites no Lean statements yet (the absence is stated loudly below). The rule *roster* is machine-checked (every mechanized rule tag round-trips to exactly one catalogue row); the statement *text* is editorial.

$$\frac{\overline{\text{dom}_k} \text{ (per-contributor dominance rows)} \quad \text{qtsl\_stochwire\_shape}(cl, sp)}{\models \text{QMarginalCompat}(sp, cl)}$$

QMARGINALCOMPAT packages marginal compatibility for stochastic wires: a belief names convex-analytic content (the indicator of a named cell set, or a registered function class), a stochastic wire carries one with its convexity, lower-semicontinuity, and properness row kits, and this node collects the per-contributor dominance rows over a shared sample space. The contributor list's shape agreement against the space is an admission demand, discharged by the shape walk quoted below.

notes Entered at the roster census (baked, never catalogued); no Lean statement binds it yet; display is schema-faithful schematic.

### Lean statement

**not yet mechanized** this rule cites no Lean statements: nothing on this page is hash-bound for it, and its dashboard row shows the same absence across the statement, receipt, and correspondence columns.

### HOL4 statement

**NO HOL STATEMENT YET**

No HOL development of the extension theory exists.

### HOL verifier receipts

**NONE**

no HOL verification receipt exists for this rule.

**Proof**

Genre: core rule (tier 1), stochastic wires. This section states the rule's soundness obligation exactly, per the catalogue's completeness-over-polish charter (a rule that can only be named-and-gapped is still a row); the discharge is open debt on the mechanization column, and the schema quoted in the entry is the baked ground truth.

**Soundness obligation.** The per-contributor dominance rows, over a shared sample space whose shape agreement with the contributor list is an admission demand, jointly certify marginal compatibility of the contributors' beliefs — the packaging judgment consumed by stochastic wire composition. The obligation is that dominance per contributor entails compatibility of the marginals on the shared space.

*Remark* R84.1 (status). No Lean statement binds this node; the convex-analytic kits (convexity, lower semicontinuity, properness) ride the stochastic wire's own rows and are consumed here by citation.

## Rule 85. QAggReduce (core rule)

### The rule (Steele metanotation)

as realized in the mechanized development; source row: `QTSL-rules.toml` — *QAggReduce*. The metanotation statement is typeset by hand for notational quality; its mechanized ground truth is the Lean statement below, extracted from the sources at every build of this book and hash-bound. The rule *roster* is machine-checked (every mechanized rule tag round-trips to exactly one catalogue row); the statement *text* is editorial, checked by eye against the extracted Lean beside it.

$$\begin{aligned}
 &(\vec{s}, \vec{k}) \in K \vdash G(\vec{s}, \vec{k}) \leq 0 \text{ (one BERNcone-family sequent over the aggregate coordinates)} \\
 &\quad s_j^P := \sum_{t:P} \phi_j(c_t), \quad k_P := \#P \text{ (the aggregate coordinates, defined)} \\
 &\quad \{\vdash l_j k_P \leq s_j^P \leq u_j k_P\}_{j,P} \text{ (coupling rows; } [l_j, u_j] \text{ a Bernstein enclosure of } \phi_j \text{ on } B_P) \\
 &\quad \{\vdash 0 \leq k_P \leq M_P\}_P \text{ (count rows)} \\
 &\{\vdash y^\top \vec{k} = y^\top \vec{k}(x_0)\}_{y \in Y} \text{ (P-invariant conservation rows: each cited witness } y \geq 0, y^\top C = 0 \text{ verified against the uncoloured skeleton's incidence)} \\
 &\quad \{\vdash (s_\alpha^P)^2 \leq k_P s_{2\alpha}^P\}_{\alpha,P} \text{ (moment rows, optional tightening)} \quad \forall x \in \text{scope}, \forall t:P \text{ in } x : c_t \in B_P \text{ (colour-box)} \\
 &\quad x \in \text{scope} \vdash G(\vec{s}(x), \vec{k}(x)) \leq 0
 \end{aligned}$$

the defined aggregate coordinates replace the certificate's feature dictionary in the display: the dictionary is certificate data (a shared reference) whose entire displayed content is the two defining equations, with  $\phi_j$  cited by the coupling rows. The enclosure box discharge is a side condition. The checker never sees a marking: the multiset quotient is compiled away producer-side, aggregate dimension independent of the marking bound  $M$ ; every row family is valid at every reachable in-scope marking under its stated premises (the moment and count-lower rows unconditionally; the count-upper row under the marking bound  $M$ ; conservation rows by their verified witness vectors, the conserved value pinned at the initial marking (the rows ride the count-row proof list — no dedicated conservation field exists on the baked node, a named schema divergence); coupling rows under their per-token bounds), so adding in-scope rows only shrinks  $K$  and never cuts a reachable in-scope aggregate point.

QAggReduce is the aggregation rule for nets whose state is a *marking* — a multiset of coloured tokens distributed over places, with variable dimension and a mandatory exchangeability quotient (tokens within a place are interchangeable, so any legitimate observable is a symmetric function of each place's colour multiset). It replaces an obligation quantified over all in-scope markings by a single polynomial obligation over finitely many *aggregate* coordinates: token counts  $k_P$  and pooled features  $s_j^P = \sum_{t:P} \phi_j(c_t)$  for a finite feature dictionary. A producer reaches for it because the alternative — flattening marking shapes into modes — explodes combinatorially in the token bound and breaks the symmetry; here obligation count and dimension are independent of the marking bound, which enters only as a constant in count rows.

What the checker recomputes: one hypothesis-carrying polynomial sequent  $G \leq 0$  over the aggregate box, whose hypothesis rows assemble the containment certificate for a polytope  $K$  covering every in-scope marking's aggregate image — coupling rows  $l_j k_P \leq s_j^P \leq u_j k_P$  from enclosures of each feature on its place's colour box, count rows  $0 \leq k_P \leq M_P$  plus linear conservation laws  $y^\top \vec{k} = y^\top \vec{k}(x_0)$  (place invariants [186], the conserved value pinned at the initial marking; each cited witness  $y \geq 0, y^\top C = 0$  checker-verified against the uncoloured skeleton's incidence matrix), and optional moment rows  $(s_\alpha^P)^2 \leq k_P s_{2\alpha}^P$  (Cauchy–Schwarz over the bag). Soundness of the reduction is evaluation: if the aggregate image lands in  $K$  and  $G \leq 0$  on  $K$ , the marking-quantified obligation holds pointwise. The whole content is the containment certificate, with each row family proven valid at its stated scope: nonnegativity and moment rows for *every* bag outright; coupling rows for every bag under their colour-scope premise (the box discharge); count bounds and conservation rows as certified reachability facts. Under those side conditions, adding a row shrinks  $K$  without ever cutting a reachable aggregate point.

What would break: a row NOT valid for every reachable marking makes  $K$  fail containment and the conclusion simply false — the central instance being the coupling rows' scope premise, since an enclosure of  $\phi_j$  on the colour box says nothing about tokens outside it; the box must be *discharged* (exit-guard transitions, an invariance proof, or stopped-process semantics), never assumed. The converse failure is honest: not every polytope point is a realizable marking, so  $K$  over-approximates — a completeness cost, refusal-shaped and never soundness-shaped, with the row menu as its dial.

**notes** The operative aggregate is the measurable-query observable  $\langle \text{marking}, f \rangle$  over bags of colours; counts and pools are the  $f \equiv 1$  and  $f = \text{id}$  degenerate queries, and a query is a semiring contraction of the count tensor against  $f$  along the colour axis. Semantically the pools are commutative-monoid folds along the tokens-to-places classifying map, with the multiset as the universal aggregate [222]; the dictionary's expressive ceiling per shape is the classical generation of multisymmetric invariants by polarized power sums [238]. The coupling rows here are deterministic pool-count arithmetic within one marking — *not* probabilistic couplings; the identically-named rows of QCOUPLEDRIFT are joint-kernel marginal data over a product of chains. Same word, disjoint mathematics, neither cites the other.

### Lean statement

BernsteinLogicAux.QtslCompose.AggReduce . **aggReduce**

statement bound

```

/-- **QAggReduce, semantic form** ("proof: evaluation"): if `G ≤ 0` on `K`
and every in-scope point's aggregate vector lands in `K`, then the

```

```

marking-quantified obligation holds. `agg` is the compiled aggregate map
`x ↦ (s(x), K(x))` — its pointwise containment (`hin`) is what the
coupling/count/moment rows + the P-invariant conservation laws certify. -/
theorem aggReduce {X A : Type*} (agg : X → A) (scope : Set X) (K : Set A)
  (G : A → ℝ) (hG : ∀ a ∈ K, G a ≤ 0) (hin : ∀ x ∈ scope, agg x ∈ K) :
  ∀ x ∈ scope, G (agg x) ≤ 0

```

BernsteinLogicAux.QtslCompose.AggReduce.coupling\_row

statement bound

```

/-- **The coupling row is valid for every marking** (NOT a probabilistic
coupling — see the module docstring's fence): if every token's `f`-value
lies in `[l, u]`, the pool-count coupling `l · k ≤ s ≤ u · k` holds. Adding
these rows to the polytope `K` never cuts a reachable aggregate point. -/
theorem coupling_row {m : Multiset C} {f : C → ℝ} {l u : ℝ}
  (hl : ∀ c ∈ m, l ≤ f c) (hu : ∀ c ∈ m, f c ≤ u) :
  l * m.card ≤ query m f ∧ query m f ≤ u * m.card

```

BernsteinLogicAux.QtslCompose.AggReduce.count\_row\_le

statement bound

```

/-- The count row's upper half, from any marking bound (the `M_P` bound is a
reachability/P-invariant fact, consumed as a hypothesis — the box-discharge
side condition [D10], not proven here). -/
theorem count_row_le {m : Multiset C} {M : ℕ} (h : m.card ≤ M) :
  (m.card : ℝ) ≤ M

BernsteinLogicAux.QtslCompose.AggReduce.count\_row\_nonneg

statement bound

```

/-- The count row's lower half: counts are nonnegative. -/
theorem count_row_nonneg (m : Multiset C) : (0 : ℝ) ≤ m.card

```

BernsteinLogicAux.QtslCompose.AggReduce.moment\_row

statement bound

```

/-- **The moment row is valid for every marking**: `(m, f)² ≤ k · (m, f²)` —
Cauchy-Schwarz over the bag (the rule display's `(s_α)² ≤ k · s_{2α}`,
with `s_α = (m, x^α)` instantiated at `f = x^α`). -/
theorem moment_row (m : Multiset C) (f : C → ℝ) :
  (query m f) ^ 2 ≤ m.card * query m (fun c => f c ^ 2)

```

BernsteinLogicAux.QtslCompose.AggReduce.query\_const\_one

statement bound

```

/-- Counts are the `f ≡ 1` degenerate query (the 14:20 correction's
normal form: `k_P = (m, 1)`). -/
theorem query_const_one (m : Multiset C) :
  query m (fun _ => (1 : ℝ)) = m.card

```

BernsteinLogicAux.QtslCompose.AggReduce.query\_count

statement bound

```

/-- **The contraction-row form** (the γ-trace): the query observable is the
count tensor contracted against `f` along the color axis. -/
theorem query_count [DecidableEq C] (m : Multiset C) (f : C → ℝ) :
  query m f = ∑ c ∈ m.toFinset, (m.count c : ℝ) * f c

```

## Correspondence (Steele display ↔ Lean)

reviewer-certified against the displayed texts

The dictionary below is a reviewer-certified statement of how the mechanized statements above interpret the displayed rule: display metavariable  $\mapsto$  Lean binder, each display hypothesis  $\mapsto$  the premise or side condition carrying it, the display conclusion  $\mapsto$  the goal — with any deliberate difference in width between display and mechanization named outright. Certification is recorded as a hash triple over (the displayed cell, the extracted statement texts, this dictionary's own text); if any of the three changes, this block turns amber until a reviewer re-certifies. The correspondence claim itself remains editorial — reviewer-grade, not machine-checked; its machine-checked successor types each soundness statement against the rule as a structured object, and supersedes this block per rule as it lands.

The displayed conclusion  $\forall x \text{ in scope: } G(\vec{s}(x), \vec{k}(x)) \leq 0 \mapsto \text{aggReduce's goal } \forall x \in \text{scope, } G(\text{agg } x) \leq 0$ , with the displayed premise  $\vdash G \leq 0$  on  $K \mapsto hG$  and the entire row apparatus  $\mapsto \text{hin} : \forall x \in \text{scope, } \text{agg } x \in K$  — the containment certificate, which the coupling/count/moment/conservation rows exist to assemble. The binder row is the biggest width fact on this page:  $\text{aggReduce}$  is stated for *any* types  $X$   $A$ , any  $\text{agg} : X \rightarrow A$ , any  $K : \text{Set } A$ , any  $G : A \rightarrow \mathbb{R}$  — no polynomiality of  $G$ , no polytopality of  $K$ , no aggregate box — so the certified semantic core is strictly wider than the displayed polynomial instance, safe direction (proof by evaluation needs none of the structure the checker needs).

- coupling rows  $l_j k_P \leq s_j^P \leq u_j k_P \mapsto \text{coupling\_row}$ : hypotheses  $\forall c \in m, l \leq f c$  and  $f c \leq u$  — the enclosure quantified over tokens *in the bag*, which is precisely where the box-discharge side condition lands in the certified statement (an enclosure on the colour box reaches the hypothesis only for markings confined to the box; the flavor text carries this as the box-discharge side condition, the statement as the membership guard).
- count rows  $0 \leq k_P \leq M_P \mapsto \text{count\_row\_nonneg}$  (unconditional) +  $\text{count\_row\_le}$ , whose bound  $m.\text{card} \leq M$  is a *hypothesis* — the  $M_P$  bound is a reachability/P-invariant fact, consumed, never proven. The displayed conservation rows  $y^\top \vec{k} = y^\top \vec{k}(x_0)$  (P-invariants, the conserved value pinned at the initial marking; witnesses  $y \geq 0, y^\top C = 0$  checker-verified) have no bound Lean counterpart at all: they are reachability facts of the net, outside this module's every-bag warrants. On the baked node they ride the count-row proof list — no dedicated conservation field exists, a named schema divergence.
- moment rows  $(s_\alpha^P)^2 \leq k_P s_{2\alpha}^P \mapsto \text{moment\_row}$ , unconditional for every bag (Cauchy–Schwarz by induction), instantiated at  $f = x^\alpha$ .
- the defined aggregate coordinates  $s_j^P := \sum_{t:P} \phi_j(c_t)$  and  $k_P := \#P \mapsto$  per-query functions  $f : C \rightarrow \mathbb{R}$ , arbitrary — polynomiality of the  $\phi_j$  is producer-side;  $\text{query\_count}$  certifies the contraction-row form  $\langle m, f \rangle = \sum_c \text{count}(c) \cdot f(c)$  (the  $\gamma$ -trace) under  $[\text{DecidableEq } C]$ , and  $\text{query\_const\_one}$  pins counts as the  $f \equiv 1$  degenerate query.

Width note: every bound row warrant is per-bag arithmetic — the multiset quotient is already taken (Multiset  $C$  IS the exchangeability-quotiented object), so the display's “the checker never sees a marking” has as its Lean face that no statement here mentions places, nets, or reachability; scope containment  $\text{hin}$  is where all of that enters, as one hypothesis. The conditional mark's content, at its exact extent: the count-bound and conservation rows are reachability facts of the net — consumed as hypotheses, never proven here — and a coupling row's colour-box confinement must be discharged by the producer (exit-guard transitions, an invariance certificate, or stopped-process semantics), never assumed. Every other row family is warranted for every bag outright.

## Lean verifier receipts

module BernsteinLogicAux.QtslCompose.AggReduce; bound build be9dbd259553... (bound from receipt bd4d8aca0400b822, 2026-07-21T04:51:40Z). A receipt records that named checking layers accepted a build: (module, compiled-artifact SHA-256, environment SHA-256, checker layers), minted when the checking gate ran; the store receipts attesting the bound build are listed with the layers each run credited. Nothing here asks the reader to trust the store: every layer is an independently runnable program over the quoted sources — rebuild the module and re-run the checkers to reproduce the verdict. Receipts attesting superseded builds credit no layer and are omitted from this rendering (the count of omissions, if any, is noted below).

## HOL4 statement

### NO HOL STATEMENT YET

The HOL4 development checks the base calculus's wire format (theory `bern_catalogue`). `QAGGREduce` is an extension-edge semantic rule whose node is baked in the extension theory; what reaches the base checker after the compile is ordinary hypothesis-carrying `BERNCONE` sequents, which the HOL side already covers as sequents without knowing their aggregation provenance. A HOL statement *about the rule* becomes writable when a checker consuming the extension theory's rows is ported.

## HOL verifier receipts

**NONE**

no HOL verification receipt exists for this rule.

**Proof**

Genre: core rule (tier 1). Scope, stated loudly: the semantic core (the aggregate-space reduction) is proven, and the row-warrant families are proven at their stated scopes — nonnegativity and moment rows for every bag, coupling rows under their colour-scope premise, while count upper bounds and place-invariant rows enter as certified in-scope reachability facts, not bagwise identities; the marking-space compile itself — producing the aggregate map and its rows from a net — is checker and compiler recomputation, outside these statements. Every hypothesis is used and remarked on.

**Setting and claim.** The state of a coloured net is a *marking*: for each place  $P$ , a finite multiset of colours drawn from a compact rational box  $B_P \subset \mathbb{R}^{n_P}$  — so the state space is a disjoint sum, over count vectors, of symmetric powers, with variable dimension and a mandatory exchangeability quotient (a “function of the state” that reads token identities is not a function on the quotient at all). The certificate language works in *aggregate coordinates*: counts  $k_P = \#P$  and pooled features  $s_j^P = \sum_{t:P} \phi_j(c_t)$  for a finite dictionary  $\Phi = \{\phi_j\}$  of polynomials. An obligation arrives as “for every in-scope marking  $x$ :  $G(\vec{s}(x), \vec{k}(x)) \leq 0$ ” with  $G$  polynomial. The rule replaces marking quantification by one polynomial sequent over a polytope  $K$  in aggregate space, whose hypothesis rows are the containment certificate. The claim (aggReduce + the row warrants): the reduction is sound, and every row family below — each under its stated scope premise — may be added to  $K$ ’s description without ever cutting a reachable aggregate point.

**Lemma R85.1** (queries, counts, and the contraction form). *For a bag  $m$  of colours and  $f : \text{colour} \rightarrow \mathbb{R}$ , write  $\langle m, f \rangle = \sum_{c \in m} f(c)$  (with multiplicity). Then  $\langle m, 1 \rangle = \#m$ , and  $\langle m, f \rangle = \sum_{c \in \text{supp}(m)} \text{count}_m(c) \cdot f(c)$  — the count tensor contracted against  $f$  along the colour axis.*

*Proof.* Both are fibre decompositions of a finite sum: group the terms of  $\sum_{c \in m} f(c)$  by value of  $c$ . Counts and pools are thus the  $f \equiv 1$  and coordinate-projection instances of one observable class, and every axis of the contraction is either summed out (colour) or an output (the query index) — there is no un-read axis, which is why, for the chosen finite dictionary, aggregate dimension is the dictionary’s index set: set by the dictionary, never by the marking.  $\square$

**Lemma R85.2** (coupling rows are valid for every bag). *If  $l \leq f(c) \leq u$  for every colour  $c$  occurring in  $m$ , then*

$$l \cdot \#m \leq \langle m, f \rangle \leq u \cdot \#m.$$

*Proof.* A sum of  $\#m$  terms, each in  $[l, u]$  (induction on the bag). In use,  $[l, u]$  is a certified enclosure of  $\phi_j$  on the colour box  $B_P$  — polynomial-enclosure machinery the calculus already owns — so the row couples the pool wire to the count wire. Two remarks. The bounds hypothesis quantifies over colours *in the bag*: the row is therefore only as good as the guarantee that tokens stay in  $B_P$  — the scope premise of **Remark R85.6**. And the degenerate case is load-bearing: at  $k_P = 0$  the two inequalities pin  $s_j^P = 0$  — emptiness is polytope geometry, not a case split.  $\square$

**Lemma R85.3** (count rows).  *$0 \leq \#m$  always; and  $\#m \leq M$  for any certified marking bound  $M$ . Linear conservation laws of the uncoloured skeleton (place invariants [186]) are further valid count rows.*

*Proof.* Cardinalities are nonnegative integers; the bound and the invariants are reachability facts of the net, consumed as hypotheses (they are certified upstream as reachability/place-invariant facts, never re-proven per obligation). Integer-valuedness of  $k_P$  is what the counting closure discipline (QCOUNTATOMROUNDING) exploits at complemented count atoms.  $\square$

**Lemma R85.4** (moment rows are valid for every bag). *For every bag  $m$  and every  $f$ :  $\langle m, f \rangle^2 \leq \#m \cdot \langle m, f^2 \rangle$ .*

*Proof.* Cauchy–Schwarz over the counting measure on the bag:  $(\sum_{c \in m} 1 \cdot f(c))^2 \leq (\sum_{c \in m} 1^2) (\sum_{c \in m} f(c)^2)$ . Instantiated at monomial features this is the family  $(s_\alpha^P)^2 \leq k_P s_{2\alpha}^P$  — optional tightenings: each one added shrinks the relaxation  $K$ , and by this lemma never below the reachable image.  $\square$

**Theorem R85.5** (soundness of QAGGREduce). *Let  $\text{agg}$  be the aggregate map  $x \mapsto (\vec{s}(x), \vec{k}(x))$ , let  $K$  satisfy  $\text{agg}(x) \in K$  for every in-scope  $x$ , and suppose the sequent  $G \leq 0$  holds on  $K$ . Then  $G(\text{agg}(x)) \leq 0$  for every in-scope  $x$ .*

*Proof.* Evaluation:  $\text{agg}(x) \in K$  and  $G \leq 0$  on  $K$ . That the proof is one line is the honest size of the semantic core — the entire content of a QAGGREduce node is the containment certificate for  $K$ , which Lemmas R85.2–R85.4 assemble from rows each valid at every reachable marking: a conjunction of per-marking-valid constraints contains the whole reachable aggregate image, so the single polynomial sequent over  $K$  (discharged by the hypothesis-carrying cone machinery of the base calculus) covers every in-scope marking at once. Obligation count and dimension are independent of the marking bound, which enters only as a constant in Lemma R85.3’s rows — the reason this rule exists instead of a mode explosion over marking shapes.  $\square$

**Remark R85.6** (the box-discharge scope premise). Lemma R85.2’s hypothesis — every occurring colour in  $B_P$  — is a claim about the *process*, and with nondegenerate diffusion a process exits every compact box with positive probability. An enclosure row quantified over states the process leaves is unsoundness, not incompleteness; so the box must be *discharged*, by one of three named routes: model box exit as a forced transition (the boundary becomes part of the model, so no in-scope state ever lies outside the box and the exit’s successor region supplies its own rows), prove invariance of the box for every reachable state (vanishing diffusion

at the boundary plus inward drift — polynomial, box-supported conditions landing in the existing row machinery), or certify the process stopped at exit — the stopped state kept inside the box, with the exit event carried in the specification’s probability budget. Which route is a per-model declaration; that *some* route is declared is a side condition of the rule. Dropping it admits the counterexample: a generator row verified on  $B_P$  says nothing at the first token that leaves, and the concluded obligation can be false on reachable states.

*Remark R85.7* (what the relaxation costs, and what it never costs).  $K$  over-approximates the reachable aggregate image — not every polytope point is a realizable marking. The cost is *completeness*: a true obligation may fail on a spurious point of  $K$  and the sequent then refuses; it is never soundness, by Theorem R85.5. The row menu is the dial: integer rounding at count atoms, conservation laws, and moment rows each cut spurious regions. The drain example, worked to its numbers in Remark R85.8, is the sharpest small witness: its interior row is *infeasible* over the real-relaxed off-target scope  $k > 0$  (it evaluates to  $+\frac{1}{4}$  at  $k = \frac{1}{2}$ ,  $s_2 = 0$ , a point no reachable marking occupies) and discharges, with an exact linear-multiplier witness, once QCOUNTATOMROUNDING tightens the scope to  $k \geq 1$  — the tightening menu earning its keep on the first toy. Conversely a row that fails at some reachable in-scope marking (a naively-cleared mean at  $k = 0$ , say) would cut reachable points and break Theorem R85.5’s containment hypothesis — validity at every reachable in-scope marking, under the row family’s stated premises, is the admission criterion for the menu: the nonnegativity and moment rows meet it for every bag outright, the coupling rows meet it once their colour-scope premise is discharged, and the count bounds and invariants meet it as certified reachability facts consumed as hypotheses.

*Remark R85.8* (the drain example, worked to its numbers). One place, colour  $x \in [-2, 2]$ , one completion transition consuming a single token at rate  $\lambda(x) = 1 + x^2$ , no source; the deadline certificate is  $V = 1 + k$  with  $\theta = \frac{1}{2}$  (counts alone suffice for  $V$ ; the pooled feature  $s_2 = \sum_t x_t^2$  enters the interior row through the rate, so its coupling row joins the scope). The generator: the continuous part vanishes ( $V$  reads no colours), and each completion removes one token, so  $\mathcal{L}V = \sum_t \lambda(x_t)(V(k-1) - V(k)) = -\sum_t (1 + x_t^2) = -(k + s_2)$ . The interior row is

$$\theta V + \mathcal{L}V = \frac{1}{2}(1 + k) - (k + s_2) = -\frac{1}{2}(k - 1) - s_2.$$

Over the real-relaxed off-target scope  $\{k > 0, 0 \leq s_2 \leq 4k\}$  — the coupling row (Lemma R85.2) at the enclosure  $x^2 \in [0, 4]$  on the colour box — the row obligation fails:  $(k, s_2) = (\frac{1}{2}, 0)$  is a scope point but no marking (counts are integers), and there the row evaluates to  $\frac{1}{2} \cdot \frac{3}{2} - \frac{1}{2} = +\frac{1}{4}$ . Once QCOUNTATOMROUNDING rounds the off-target scope  $\text{cmpl}\{k \leq 0\}$  to  $k \geq 1$ , the rewriting displayed above is the exact linear-multiplier witness: multiplier  $\frac{1}{2}$  on the scope row  $k - 1 \geq 0$  and 1 on the coupling floor  $s_2 \geq 0$  reproduce the row identically — a polynomial identity, no residue, no numerics — and the certificate is tight at  $(k, s_2) = (1, 0)$ : the single-cold-token state, the true bottleneck, since the slowest completion rate is  $\lambda(0) = 1$ . Every number cited in Remark R85.7 recomputes from this display; the example’s other rows (floor, atom, root) are not the story here and are not staged.

*Remark R85.9* (relation to the literature). The aggregate coordinates are the classical multisymmetric power sums: per fixed shape, polarized power sums generate the full invariant algebra in characteristic 0 [238], which locates the dictionary’s expressiveness ceiling (generation degree grows with the shape — a resolution bound, priced as completeness, never claimed away). Degree-one certificates in counts alone recover classical place-invariant analysis [186]. Semantically, pools are commutative-monoid folds along the tokens-to-places classifying map, with the multiset as the universal aggregate every other one factors through [222] — exchangeability and factoring-through-the-free-commutative-monoid are the same statement from two sides. The identically-named “coupling rows” of the relational tier (QCOUPLEDRIFT) are probability couplings over a product of chains; the rows here are deterministic pool-count arithmetic within one marking. Same word, disjoint mathematics, deliberately uncited in both directions.

## Rule 86. QCOUNTATOMROUNDING (alias rule)

### The rule (Steele metanotation)

as realized in the mechanized development; source row: QTSL-rules.toml — *QCountAtomRounding*. The metanotation statement is typeset by hand for notational quality; its mechanized ground truth is the Lean statement below, extracted from the sources at every build of this book and hash-bound. The rule *roster* is machine-checked (every mechanized rule tag round-trips to exactly one catalogue row); the statement *text* is editorial, checked by eye against the extracted Lean beside it.

$$\frac{k_P \text{ a count observable, integer-valued at every reachable marking} \quad j \in \mathbb{Z}}{\text{cmpl } \{k_P \leq j\} \rightsquigarrow \{k_P \geq j+1\} \quad (\text{hypothesis positions, reachable scope})}$$

integrality is the compile's guarantee. Exact over the reachable locus (the complement over reachable markings is  $\{k_P \geq j+1\}$ , not  $\{k_P > j\}$ ), and unconditionally never wider ( $\{k_P \geq j+1\} \subseteq \{k_P > j\}$ ) — rounding to the next integer is free and strictly tighter than the real complement, the counting analogue of the strict-atom closure discipline.

QCOUNTATOMROUNDING is the counting closure discipline: when a count observable  $k_P$  is complemented in a hypothesis position, the real-arithmetic complement of  $\{k_P \leq j\}$  — the open condition  $\{k_P > j\}$  — is replaced by the closed integer-rounded atom  $\{k_P \geq j+1\}$ . Over reachable markings the two are *equal* (counts are integers there), and everywhere the rounded atom is contained in the open one, so the rewrite is free and never wider than the real complement — strictly tighter wherever the slab is realized: substituting it in hypothesis position never widens the constraint set, and the gained slab  $j < k_P < j+1$  (unreachable, but visible to real-arithmetic relaxations) is often exactly what makes a downstream combination certificate feasible. It is the counting analogue of the strict-atom closure discipline for continuous observables, with integrality replacing topology.

There is nothing for the checker to recompute beyond the syntactic rewrite itself: producers apply it before emission, and what the wire carries is the already-tightened atom inside an aggregation rule's hypothesis rows. The one genuine hypothesis is integrality — that  $k_P$  takes integer values at every reachable marking. That is a guarantee of the marking-space compile (counts are cardinalities), not of the rewrite; in the mechanization it enters as a named hypothesis, discharged definitionally when the net layer lands. Without it the exactness identity fails (a fractional “count” at  $k_P = j + \frac{1}{2}$  satisfies the true complement but not the rounded atom), and only the containment direction survives — which is not enough in hypothesis position: the rounded scope is *smaller*, so a row verified only on it silently skips exactly such fractional points, and a misapplied rounding can silently accept rather than refuse (the proof section's integrality remark carries the witness). The integrality warrant is load-bearing for soundness, not a convenience.

**notes** Load-bearing on the first worked aggregation example: a drain net's interior row is infeasible over the real-relaxed off-target scope  $k > 0$  (it fails at  $k = \frac{1}{2}$ ) and discharges with the rounded scope  $k \geq 1$ , via an exact linear-multiplier witness. The rewrite rides with QAGGREDUCE's family: its target is an atom-denotation identity consumed by count rows, not a separate rule node — one atom in, one atom out.

### Lean statement

BernsteinLogicAux.Structural .countAtomRounding\_sound

statement bound

```
/-- **P3.3 CountAtomRounding**, the soundness side (hypothesis position):
every reachable point of the true complement of `{k ≤ j}` satisfies the
tightened atom `{j + 1 ≤ k}`. This is the side the drain example's interior
row consumes — the aggregate polytope `K` must contain every in-scope
reachable point, and it does. -/
theorem countAtomRounding_sound (k : X → ℝ) (j : ℤ) (Reach : Set X)
  (hbridge : ∀ x ∈ Reach, ∃ n : ℤ, k x = (n : ℝ)) :
  ∀ x ∈ Reach, x ∈ {x | k x ≤ (j : ℝ)}c → (j : ℝ) + 1 ≤ k x
```

BernsteinLogicAux.Structural .countAtomRounding\_tighter

statement bound

```
/-- **P3.3**, the free-tightening direction: the rounded atom is contained
in the real complement unconditionally — substituting it never widens the
constraint set, so the rewrite is strictly tighter (by the cut
`{j, j+1}`), which is what buys the drain example its Farkas
feasibility. Stated at any real threshold `j`: the containment needs no
integrality — only exactness (`countAtomRounding_eq`) and soundness
(`countAtomRounding_sound`) ride the integer-threshold bridge. -/
theorem countAtomRounding_tighter (k : X → ℝ) (j : ℝ) :
  {x | j + 1 ≤ k x} ⊆ {x | j < k x}
```

BernsteinLogicAux.Structural .countAtomRounding\_eq

statement bound

```

/-- **P3.3**, exactness on the reachable locus: over integer-valued points
the rewrite loses nothing — the catalogue's "the complement ... over
reachable markings IS  $\{k_P \geq j + 1\}$ ", verbatim as a set identity. -/
theorem countAtomRounding_eq (k : X → ℝ) (j : ℤ) (Reach : Set X)
  (hbridge : ∀ x ∈ Reach, ∃ n : ℤ, k x = (n : ℝ)) :
  Reach n {x | k x ≤ (j : ℝ)}c = Reach n {x | (j : ℝ) + 1 ≤ k x}

```

## Correspondence (Steele display ↔ Lean)

**reviewer-certified against the displayed texts** The dictionary below is a reviewer-certified statement of how the mechanized statements above interpret the displayed rule: display metavariable  $\mapsto$  Lean binder, each display hypothesis  $\mapsto$  the premise or side condition carrying it, the display conclusion  $\mapsto$  the goal — with any deliberate difference in width between display and mechanization named outright. Certification is recorded as a hash triple over (the displayed cell, the extracted statement texts, this dictionary's own text); if any of the three changes, this block turns amber until a reviewer re-certifies. The correspondence claim itself remains editorial — reviewer-grade, not machine-checked; its machine-checked successor types each soundness statement against the rule as a structured object, and supersedes this block per rule as it lands.

The entry's two claims (exactness and never-wider, now the flavor text) and the displayed integrality premise map onto the three bound statements. The compile's integrality guarantee — the rule's System bridge, as the roster says in words —  $\mapsto$  `hbridge : ∀ x ∈ Reach, ∃ n : ℤ, k x = (n : ℝ)`: counts integer-valued at every reachable point, a named hypothesis because lean-aux lacks the net layer that guarantees it. Then: the hypothesis-position rewrite  $\mapsto$  `countAtomRounding_sound` (every reachable point of the true complement of  $\{k \leq j\}$  satisfies  $\{j + 1 \leq k\}$  — the side the drain example's interior row consumes); “unconditionally never wider”  $\mapsto$  `countAtomRounding_tighter`, whose binder row is the width find: NO integrality, NO reachable scope — the containment  $\{j + 1 \leq k\} \subseteq \{j < k\}$  holds for arbitrary real observables, so the substitution never *widens* anywhere; soundness of the hypothesis-position substitution itself rides the exactness side — the integrality hypothesis — certified separately as `countAtomRounding_eq` — the catalogue's “the complement over reachable markings IS  $\{k_P \geq j + 1\}$ ” verbatim as a set identity on the reachable locus. Width note:  $k : X \rightarrow \mathbb{R}$  throughout; `_tighter` now takes  $j : \mathbb{R}$  outright (the containment needs no integrality, so the anchor is stated at the proposition's full width), while `_sound` and `_eq` keep the  $j : \mathbb{Z}$  cast their integer-threshold bridge demands — the count-observable grammar (the  $f \equiv 1$  query) is upstream; divergence D2's question (which side is load-bearing) is answered by the bind structure itself: soundness rides `_sound`, the free tightening rides `_tighter`, and each is consumable independently.

## Lean verifier receipts

module BernsteinLogicAux.Structural; bound build 1222cdcc326f... (bound from receipt cb0c3820c6877f22, 2026-07-29T01:03:36Z). A receipt records that named checking layers accepted a build: (module, compiled-artifact SHA-256, environment SHA-256, checker layers), minted when the checking gate ran; the store receipts attesting the bound build are listed with the layers each run credited. Nothing here asks the reader to trust the store: every layer is an independently runnable program over the quoted sources — rebuild the module and re-run the checkers to reproduce the verdict. Receipts attesting superseded builds credit no layer and are omitted from this rendering (the count of omissions, if any, is noted below).

| receipt          | minted               | layers                             | status  |

## HOL4 statement

### NO HOL STATEMENT YET

The HOL4 development checks the base calculus's wire format (theory `bern_catalogue`). This rewrite is applied producer-side, before emission: even with the aggregation node baked, the wire is expected to carry the already-tightened atom, so the HOL statement that would matter is the aggregation sequent's — and no checker consuming the extension theory's rows is ported yet. Nothing exists for a HOL statement to be about; if a future format ever carries the un-rounded atom, the rewrite's exactness identity becomes the portable statement.

## HOL verifier receipts

### NONE

no HOL verification receipt exists for this rule.

## Proof

Genre: alias rule (tier 3) — a respelling template. One variation from the alias norm, stated up front: the unpack's target is an *atom-denotation identity* consumed by QAGGREDUCE's count rows (the pattern of the strict-atom closure moves), not a separate rule node — one atom in, one atom out, producers rewrite before emission. The five alias artefacts follow in that key: the unpack, the filled-in application, the payload transport, the exactness identity, and the soundness corollary.

**Recipe R86.1** (the respelling). The unpack acts on a complemented count atom in hypothesis position:

$$\text{cml}\{k_P \leq j\} \quad \rightsquigarrow \quad \{k_P \geq j + 1\}, \quad j \in \mathbb{Z},$$

where  $k_P$  is a count observable — integer-valued at every reachable marking, because counts are cardinalities (the compile's integrality guarantee, entering the mechanization as a named hypothesis until the net layer discharges it definitionally). Payload transport, field for field:

| field       | before                          | after                         |
|-------------|---------------------------------|-------------------------------|
| observable  | $k_P$                           | $k_P$ (verbatim)              |
| threshold   | $j$                             | $j + 1$ (integer bump)        |
| orientation | complemented $\leq$ (open $>$ ) | closed $\geq$                 |
| scope       | reachable markings              | reachable markings (verbatim) |

The filled-in application is a scope row of an aggregation obligation: where a compile node scopes a row “off the target  $\{k_P \leq j\}$ ”, the row's hypothesis list carries  $k_P \geq j + 1$  in place of the real-arithmetic complement.

**Proposition R86.2** (exactness over the reachable locus). *On integer-valued points, for  $j \in \mathbb{Z}$ ,  $\text{Reach} \cap \text{cml}\{k_P \leq j\} = \text{Reach} \cap \{k_P \geq j + 1\}$ . (Both restrictions are load-bearing: at a non-integer threshold the integer  $n = \lceil j \rceil$  would satisfy  $n > j$  but not  $n \geq j + 1$ .)*

*Proof.* At a reachable point,  $k_P = n$  for some integer  $n$ ; and for integers,  $n > j \iff n \geq j + 1$ . Two lines, which is the point: the complement of  $\{k_P \leq j\}$  over reachable markings is  $\{k_P \geq j + 1\}$ , not  $\{k_P > j\}$  — nothing is lost.  $\square$

**Proposition R86.3** (free tightening, unconditionally).  $\{k_P \geq j + 1\} \subseteq \{k_P > j\}$  on all points, integer-valued or not.

*Proof.*  $j + 1 \leq k_P$  implies  $j < k_P$ . So substituting the rounded atom in hypothesis position never widens the constraint set; what it removes is exactly the slab  $j < k_P < j + 1$  — strictly, whenever that slab's preimage is nonempty: unreachable by any marking, but fully visible to a real-arithmetic relaxation, which is where the gain lands.  $\square$

**Proposition R86.4** (soundness corollary). *Every reachable point of the true complement of  $\{k_P \leq j\}$  satisfies the tightened atom; hence any row valid on  $\text{Reach} \cap \{k_P \geq j + 1\}$  is valid on the reachable part of the true complement — the direction hypothesis positions consume, and by Proposition R86.2 nothing more is being assumed than the complement itself, reachably.*

*Proof.* Immediate from Proposition R86.2, left-to-right. The asymmetry of positions is worth one sentence: in *hypothesis* position a tighter scope is free (fewer points to verify, no reachable point dropped, by exactness); in *conclusion* position a tightened atom would be a stronger claim and is not licensed by this rule — the alias is a hypothesis-position discipline, exactly like its continuous sibling.  $\square$

**Remark R86.5** (why integrality is not decoration). Drop it and exactness fails: a fractional “count” at  $k_P = j + \frac{1}{2}$  satisfies the true complement but not the rounded atom, so a row verified only on the rounded scope would silently skip it — if such points were reachable, that is unsoundness in hypothesis position. The integrality hypothesis is precisely the statement that they are not: counts are cardinalities of token multisets. Note there is *no* graceful failure mode when the rewrite is misapplied to a non-count observable: in hypothesis (scope) position the rounded atom *shrinks* the region a row must be verified on, so misapplication can silently accept — the half-integer point above is exactly the witness. The integrality warrant is load-bearing, not a convenience.

**Remark R86.6** (load-bearing on the first worked example). The drain net's deadline certificate needs its interior row off the target  $\{k \leq 0\}$ . Over the real-relaxed scope  $k > 0$  the row is infeasible — it evaluates to  $+\frac{1}{4}$  at  $(k, s_2) = (\frac{1}{2}, 0)$ , a point no marking occupies — while over the rounded scope  $k \geq 1$  it discharges with an exact linear-multiplier witness (both numbers recompute

in the QAggReduce section’s drain-example remark, where the row and its multipliers are displayed). The rounding is the counting analogue of the strict-atom closure discipline (polarity-directed rounding of strict literals), with integrality playing the role topology plays there: both convert an open condition into the closed atom the row machinery wants, at zero semantic cost on the states that matter.

| proof step         | formal anchor                                                                                                                                           |

## Rule 87. QPALWAYSFROMFOLD (core rule)

### The rule (Steele metanotation)

as realized in the mechanized development; source row: QTSL-rules.toml — *QPalwaysFromFold*. The metanotation statement is typeset by hand for notational quality; this rule cites no Lean statements yet (the absence is stated loudly below). The rule *roster* is machine-checked (every mechanized rule tag round-trips to exactly one catalogue row); the statement *text* is editorial.

$$\frac{\text{upper} : \text{qpaf\_upper}(n, c_u) \quad \text{lower} : \text{qpaf\_lower}(n, c_l) \quad \text{qtsl\_palways\_fold}(n)}{\mathcal{M} \models \text{SProbGE}(p, \text{PAlways}(\text{SAnd}[\text{SAtomLE}(c, V), \text{SAtomGE}(c, V)]))}$$

QPALWAYSFROMFOLD ties plated-fold safety evidence to the judgment stratum: it concludes a surely-invariant claim — a conserved-charge invariant, held with probability one — over the demonic composite of a token-population subject, from certificates about a plated fold of the population. Coverage telescopes footprint rows *pathwise* across every resolution of every clock wing: the telescoping argument reads firings, not clocks, so race, demonic, and forced transitions are covered uniformly and no scheduler resolution escapes. Initial membership is checked inside the evaluator's walk (the deadline-table precedent): there is no warrant row, no region-level child, and no boxed region — the subject's marking is unbounded, and a boxed region for it would be a type error, not a convenience.

A producer cites one certificate per direction: an upper-bound citation for the  $\leq$  face, a lower-bound citation for the  $\geq$  face — at least one, at most one row each; the lower's features are recomputed by the walk, never trusted. The accepted conclusion shapes are one atom or the displayed two-sided conjunction with equal polynomials; anything wider refuses loudly (a narrow walk mis-verifies nothing).

**notes** The verification content lives in the evaluator's walk, whose semantics are normative in the plated-transfer design: conclusion resolution, spec shape, atom decomposition, cert citations, subject agreement including the plate-to-population token bindings, fold scale, polynomial correspondence against the count-wire enumeration, init membership from the bag marking, sibling-claim presence, and the polarity roster — with the pathwise-species demand on covered transitions: an expectation-species footprint row never warrants a surely-invariant. No Lean statement binds the node yet; the schema and walk are baked, the walk mutant is red in the theory battery, and the mechanization column is honest open debt.

### Theory rows (geolog)

The rule's certificate content as it is declared in the geolog theory the checker loads — payload schema, side-condition demands, and axiom rows, quoted from the theory source at every build of this catalogue (a stale quotation cannot exist). Axiom modes: *chase* = the engine derives; *report* = a violation is a loud judgment; *refuse* = a violation gates admission. Side-condition relations are discharged by bounded evaluation at the engine's ground seam, never by derivation.

The baked rows: the node, its direction citations, the walk, and the plate-population binding the walk's subject-agreement step reads.

## Lean statement

**not yet mechanized** this rule cites no Lean statements: nothing on this page is hash-bound for it, and its dashboard row shows the same absence across the statement, receipt, and correspondence columns.

## HOL4 statement

### NO HOL STATEMENT YET

No HOL development of the extension theory exists; this node's content is walk structure over baked rows.

## HOL verifier receipts

### NONE

no HOL verification receipt exists for this rule.

## Proof

Genre: core rule (tier 1), the plated-transfer genus (safety face). This section states the rule's soundness obligation exactly, per the catalogue's completeness-over-polish charter (a rule that can only be named-and-gapped is still a row); the discharge is open debt on the mechanization column, and the schema quoted in the entry is the baked ground truth.

**Soundness obligation.** With the walk's ten steps discharged — conclusion resolution, spec shape, atom decomposition, direction citations, subject agreement including plate-to-population token bindings, fold scale, polynomial correspondence against the count-wire enumeration, initial membership from the bag marking, sibling-claim presence, and the polarity roster with its pathwise-species demand — the cited fold certificates' footprint rows telescope pathwise across every resolution of every clock wing, so the conserved-charge invariant holds along every run: the concluded claim holds surely, and any probability threshold in  $(0, 1]$  is sound.

*Remark* R87.1 (status). No Lean statement binds this node. The walk semantics are normative in the plated-transfer design; the walk mutant is red in the theory battery, which certifies the walk's presence, not the transfer theorem — the transfer theorem's mechanization is the open debt.

## Rule 88. QFIREBOUNDFROMFOLD (core rule)

### The rule (Steele metanotation)

as realized in the mechanized development; source row: `QTSL-rules.toml` — `QFireBoundFromFold`. The metanotation statement is typeset by hand for notational quality; this rule cites no Lean statements yet (the absence is stated loudly below). The rule *roster* is machine-checked (every mechanized rule tag round-trips to exactly one catalogue row); the statement *text* is editorial.

$$\frac{\text{cert} : \text{HCert} \quad d_{\min} > 0 \quad \text{qtsl\_firebound\_fold}(n)}{\mathcal{M} \models \text{SReturnLE}(B, \text{retFireCount}(trs))}$$

QFIREBOUNDFROMFOLD is the ranking face of the same genus: from *one* gap-rowed plated certificate it concludes a roster firing-count ceiling — the specification's warranted component is the count bound over the roster firing-count run functional. The transfer theorem's pathwise face, applied: with footprint, coverage, floor, and flow discharged, every roster firing drops the fold by at least  $d_{\min}$  in the reading scale, the fold never rises anywhere else, and the fold is floored at zero — so roster firings number at most  $\text{fold}_{\varphi}(m_0)/d_{\min}$  along *every* run, uniformly in token count and interleaving.

What the checker recomputes: two exact inequalities — each roster row's gap at least  $d_{\min}$ , and  $B \cdot d_{\min}$  at least the fold's initial value — and never an argmin:  $d_{\min}$  is pinned by the producer, the same witness species as a pinned tolerance. Counting is firing-metered per roster member — deliberately not region-entry counting (the crossing-count acceptance device) and not the instant-crossing count (the crossing-budget family's compensator-mass species): three counting species, three devices, none interchangeable.

**notes** Closed-judgment route, deliberately: no warrant row, no region-level child, no boxed certificate-family table for an unbounded marking; init arithmetic lives inside the walk. The cert citation is a function, not a relation — a ranking consequence cites exactly one certificate, and exactly-one is semantic here (totality is the sort's own obligation); contrast the safety sibling's two-direction relation shape. No Lean statement binds the node yet; the schema, the positivity report row, and the walk are baked with red mutants in the theory battery, and the mechanization column is honest open debt.

### Theory rows (geolog)

The rule's certificate content as it is declared in the geolog theory the checker loads — payload schema, side-condition demands, and axiom rows, quoted from the theory source at every build of this catalogue (a stale quotation cannot exist). Axiom modes: *chase* = the engine derives; *report* = a violation is a loud judgment; *refuse* = a violation gates admission. Side-condition relations are discharged by bounded evaluation at the engine's ground seam, never by derivation.

The baked rows: the node with its pinned decrement, the positivity report, the walk, and the roster relation the concluded run functional reads.

## Lean statement

**not yet mechanized** this rule cites no Lean statements: nothing on this page is hash-bound for it, and its dashboard row shows the same absence across the statement, receipt, and correspondence columns.

## HOL4 statement

### NO HOL STATEMENT YET

No HOL development of the extension theory exists; this node's content is walk structure over baked rows.

## HOL verifier receipts

### NONE

no HOL verification receipt exists for this rule.

## Proof

Genre: core rule (tier 1), the plated-transfer genus (ranking face). This section states the rule's soundness obligation exactly, per the catalogue's completeness-over-polish charter (a rule that can only be named-and-gapped is still a row); the discharge is open debt on the mechanization column, and the schema quoted in the entry is the baked ground truth.

**Soundness obligation.** With footprint, coverage, floor, and flow discharged for the one gap-rowed certificate, every roster firing drops the fold by at least  $d_{\min}$  in the reading scale, the fold never rises anywhere else, and the fold is floored at zero; hence roster firings number at most  $\text{fold}_{\varphi}(m_0)/d_{\min}$  along every run, uniformly in token count and interleaving — the concluded firing-count ceiling. The checker's contribution is two exact inequalities (each roster row's gap at least  $d_{\min}$ ; the ceiling times  $d_{\min}$  at least the fold's initial value);  $d_{\min}$  is pinned by the producer and never derived.

*Remark R88.1 (status).* No Lean statement binds this node. The walk semantics are normative in the transfer-former design (twelve steps); the theory battery's mutants are red at the walk and positivity loci.

## Rule 89. QPALWAYSFROMFOLD (core rule)

### The rule (Steele metanotation)

as realized in the mechanized development; source row: QTSL-rules.toml — *QPalwaysTFromFold*. The metanotation statement is typeset by hand for notational quality; this rule cites no Lean statements yet (the absence is stated loudly below). The rule *roster* is machine-checked (every mechanized rule tag round-trips to exactly one catalogue row); the statement *text* is editorial.

$$\frac{n \text{ horizon} = T \quad \text{coverage\_lb}(c) \quad \begin{array}{c} n \text{ cert} = c \quad n \text{ goalfold} = f_g \\ \text{flow\_lb}(c) \quad \forall r. u_r > 0 \Rightarrow \text{TrMeter}(tr(r), d_r) \end{array} \quad \text{qtsl\_palwayst\_fold}(n)}{\mathcal{M} \models \text{SProbGE}(p, \text{PALwaysT}(T, \text{cml}(goal)))}$$

QPALWAYSFROMFOLD is the timed-floor face of the plated-transfer genus — the third sibling beside QPALWAYSFROMFOLD (safety) and QFIREBOUNDFROMFOLD (ranking): from one certificate whose footprint rows carry the *drop-at-most* polarity (per firing, the fold decreases by at most  $u_r$  — including  $u_r = 0$ , never decreases), together with per-row clock floors, it concludes that no run of the system reaches a designated goal region within a horizon  $T$  — a surely-satisfied time-bounded invariance claim over the goal's complement.

The soundness assembly is the transfer telescope's mirror face plus a meter law: with drop-at-most coverage of every may-touch transition, mirror flow, per-row footprint sequents, and — for conjugated reading kinds — the conjugation-parameter conformance discharged (integrality of conjugated powers and the order-preservation domain; the transformed-space telescope is unjustified without it), every run satisfies  $\text{fold}_\varphi(m_t) \geq \text{fold}_\varphi(m_0) - \sum_r u_r N_r(t)$ ; with clock floors  $d_r > 0$  on every counted row,  $N_r(t) \leq \max(0, (t - o_r)/d_r) + 1$  under every resolution. A run reaching the goal region (where the fold is at most  $f_g$ ) by time  $T$  would force  $\text{fold}_\varphi(m_0) - f_g \leq \sum_{r:u_r>0} u_r \cdot (\max(0, (T - o_r)/d_r) + 1)$  — and the checker's whole trusted contribution is ONE exact rational verification of the strict reverse inequality.  $T$ ,  $f_g$ , and every  $u_r$  are pinned by the producer; the checker never computes an argmin or an optimum.

Counting from below stays deliberately *inside* the walk: the specification language refuses a standing “at least  $n$  events occur” former (a liveness claim consuming survival mass), and this rule honors that refusal — the conclusion is safety-polarity, violated by finite prefixes. The conclusion is Zeno-robust without any crossing budget: rows with  $u_r = 0$  (instantaneous rows included) may fire unboundedly, since they cannot drop the fold; an instantaneous row with  $u_r > 0$  refuses outright (it has no time floor to meter).

**notes** The schema is baked in the extension theory: the node, the fourteen-step walk (normative in the judgment-tie design), the two mirror side-conditions, the per-wing meter demands, and the drop-at-most footprint polarity are all landed rows, quoted below from the theory source. The polarity's formation carried its guard obligations into the bake — most critically that the *existing* upper-coverage side condition counts exactly rows of the two elder polarities (safety, gap), stated as a closed positive membership rather than a prohibition: a drop-at-most row bounds nothing above, and an evaluator that counted one would unsound the two elder siblings. The mechanization ladder names the discrete-unfolding profile first (round-indexed runs); the continuous lift waits on a first formalization of the clock meter semantics, shared with QRATEFROMCLOCK and QPALWAYSFROMLINEAGE. No Lean statement binds the node yet; the mechanization column is honest open debt.

### Theory rows (geolog)

The rule's certificate content as it is declared in the geolog theory the checker loads — payload schema, side-condition demands, and axiom rows, quoted from the theory source at every build of this catalogue (a stale quotation cannot exist). Axiom modes: chase = the engine derives; report = a violation is a loud judgment; refuse = a violation gates admission. Side-condition relations are discharged by bounded evaluation at the engine's ground seam, never by derivation.

The baked rows: the node with its pinned horizon and goal-fold fields, the optional lineage-offsets citation, the walk, the two mirror side-conditions on the cited certificate, the per-wing meter demands, and the drop-at-most polarity with its displacement bound.

## Lean statement

**not yet mechanized** this rule cites no Lean statements: nothing on this page is hash-bound for it, and its dashboard row shows the same absence across the statement, receipt, and correspondence columns.

## HOL4 statement

### NO HOL STATEMENT YET

No HOL development of the extension theory exists; this node's content is walk structure over baked rows.

## HOL verifier receipts

### NONE

no HOL verification receipt exists for this rule.

## Proof

Genre: core rule (tier 1), the plated-transfer genus (timed-floor face). This section states the rule's soundness obligation exactly, per the catalogue's completeness-over-polish charter; the rule's schema and walk are baked in the extension theory (rows quoted in this section), and the discharge below is the named obligation of the mechanization column.

**Soundness obligation (mirror telescope + meter law).** Let  $F := \text{fold}_\varphi(m_0)$ , recomputed by the walk from the declared initial marking. (Telescope.) With drop-at-most coverage of every may-touch transition, per-row footprint sequents (produced-side fold contribution at least consumed side minus  $u_r$ , in the reading scale, under the guard hypotheses, for all colors in the boxes), mirror flow (the fold does not decrease between firings), and — for conjugated reading kinds — the conjugation-parameter conformance (integrality of conjugated powers; the order-preservation domain, even powers requiring certified nonnegative feature ranges: without it the transformed-space reading of the telescope is unjustified) discharged, every run satisfies  $\text{fold}_\varphi(m_t) \geq F - \sum_r u_r N_r(t)$ , where  $N_r(t)$  counts firings of row  $r$  by time  $t$ . (Meter.) With every counted row ( $u_r > 0$ ) carrying a clock floor  $d_r > 0$  and first-firing offset  $o_r$  (from a cited lineage node, else the one-dwell default  $o_r := d_r$ ),  $N_r(t) \leq \max(0, (t - o_r)/d_r) + 1$  under every resolution. (Assembly.) The goal region carries a certified fold ceiling  $f_g$ ; a run reaching it at  $t \leq T$  forces  $F - f_g \leq \sum_r u_r N_r(t) \leq \sum_{r:u_r>0} u_r \cdot (\max(0, \frac{T-o_r}{d_r}) + 1)$ , using  $u_r \geq 0$  throughout and monotonicity in  $t$ ; the checker-verified strict inequality  $\sum_{r:u_r>0} u_r \cdot (\max(0, \frac{T-o_r}{d_r}) + 1) < F - f_g$  refutes it, so no admitted run reaches the goal region within  $T$  — the concluded time-bounded invariance, surely.

The conclusion is safety-polarity and consumes no crossing budget: rows with  $u_r = 0$  (instantaneous rows included) may fire unboundedly without touching the telescope's right side; an instantaneous row with  $u_r > 0$  refuses at the walk's meter step.

*Remark R89.1 (status).* The schema is baked: the node, its fourteen-step walk, the mirror side-conditions, the per-wing meter demands, and the drop-at-most polarity are landed theory rows (quoted in this section). No Lean statement binds the node yet: the named obligation is the discrete-unfolding profile first (round-indexed runs), with the continuous lift behind the clock meter semantics' first formalization — the keystone shared across this rule family.

## Rule 90. QPALWAYSFROMLINEAGE (core rule)

### The rule (Steele metanotation)

as realized in the mechanized development; source row: QTSL-rules.toml — *QPalwaysTFromLineage*. The metanotation statement is typeset by hand for notational quality; this rule cites no Lean statements yet (the absence is stated loudly below). The rule *roster* is machine-checked (every mechanized rule tag round-trips to exactly one catalogue row); the statement *text* is editorial.

$$\frac{\text{unit\_lineage}(c) \quad \{\text{hrpGap}(1), \text{hrpDropAtMost}(1)\} \text{ per advancing row on } \chi = -\psi \text{ (pathwise species)}}{\text{TrMeter}(tr(r), d) \text{ per advancing row} \quad \forall \tau \in m_0. \psi(\tau) \leq 0 \quad T < k \cdot d \quad \text{qtsl\_palwayst\_lineage}(n)} \\ \mathcal{M} \models \text{SProbGE}(p, \text{PALwaysT}(T, \bigwedge_{q: \text{depth}(q) \geq k} \text{count}_q = 0))$$

QPALWAYSFROMLINEAGE is a causal-depth meter: tokens whose production chain has depth  $k$  cannot exist strictly before time  $k \cdot d$ . It concludes plate-emptiness — no token of declared causal depth at least  $k$  exists at any time  $t \leq T$ , for a pinned horizon  $T$  checked STRICTLY below  $k \cdot d$  (the induction proves emptiness through round  $k - 1$  and permits a depth- $k$  token in the round- $k$  marking, so the inclusive endpoint is deliberately not concluded; on the round grid  $T = (k - 1) \cdot d$  is the tightest warranted choice, and  $k$  is a positive integer) — from four ingredients: *unit lineage* (every covered transition consumes at most one and produces at most one token across the cited plates, so per-token lineage is a path: for a row consuming a cited token and producing a cited successor, the fold-level displacement of the depth dictionary is the successor's depth minus the consumed token's; birth rows root at depth at most one, and a death row on a positive-depth token satisfies neither bracket and is refused — a completeness cost, never an unsoundness); a *bracket* of footprint rows on the negated depth dictionary pinning each chain firing's advance to exactly one (the drop-at-most row and the gap row at equal witness — both sides load-bearing, since a decrease bound alone would admit one firing advancing depth by ten — and every bracket row of the pathwise deterministic-reset species: a stochastic moment row could satisfy both sequents at expected advance one while individual outcomes jump farther, defeating the surely conclusion); clock floors  $d$  on every advancing row; and initial depth at most zero, recomputed by the walk from the declared initial marking (universally over its tokens — vacuous when empty).

The rule has a second face: a QPALWAYSFROMFOLD node may cite it as the source of its per-row first-firing offsets ( $o_r :=$  the row's consumed-tuple minimum declared depth over the guard box, times  $d$  — recomputed by the CONSUMING walk, never read from stored producer data, because an inflated offset errs on the unsound side; a row whose guard box admits no consumed cited token takes the consumer's one-dwell default instead). This face is unaffected by the strict endpoint: a firing that consumes a depth- $k$  token happens at round  $k$  or later, time at least  $k \cdot d$ , which is exactly the offset claim.

The rule mints *profile-gated*, and the gate is stated honestly rather than smoothed over: per-token chain spacing is NOT derivable from the per-transition meter law when several tokens share a guard — a transition's accrued dwell can be spent on a freshly produced token. This is the classical timed-Petri-net memory-policy fork (single-server versus per-token timers). The profile, exactly: every covered row carries the one period  $d$  as its dwell parameter (demonic and forced wings admitted; a carved wing at floor equal to ceiling  $d$ , so firings cannot fall off the round grid); the subject is declared at the round-indexed step reading — firings at round  $r$  read the round- $r$  marking and produce into round  $r + 1$ , rounds at times  $r \cdot d$ , the theory's own discrete-time-unfolding reading, whose canonical case is the all-demonic uniform-dwell net; and the cited plates' token colors do not evolve between firings (the brackets constrain firing displacement only, so between-round color drift would evade them). Under that profile the per-token spacing IS the step law's own content and the soundness induction is clean; the continuous-time lift is a genuine semantics decision the proposal prices without baking.

**notes** The schema is baked in the extension theory: the node, its walk, and its structural side-conditions are quoted below from the theory source. Profile-gated from birth, per the catalogue's precedent of rules proven at a named profile and filed beyond it; the concluded specification former itself is profile-independent — the gate lives in the walk's side conditions, never in the conclusion's meaning. A worked instance of the discrete induction (a fabrication-line model with a 370-deep production chain) is already kernel-checked; the oracle obligation that generalizes it to the profile rule remains owed, and no Lean statement binds the node yet — the mechanization column is honest open debt.

### Theory rows (geolog)

The rule's certificate content as it is declared in the geolog theory the checker loads — payload schema, side-condition demands, and axiom rows, quoted from the theory source at every build of this catalogue (a stale quotation cannot exist). Axiom modes: *chase* = the engine derives; *report* = a violation is a loud judgment; *refuse* = a violation gates admission. Side-condition relations are discharged by bounded evaluation at the engine's ground seam, never by derivation.

The baked rows: the node with its positive depth, positive period, and nonnegative horizon reports, the unit-lineage structural side-condition on the cited certificate, and the causal-depth walk.

## Lean statement

**not yet mechanized** this rule cites no Lean statements: nothing on this page is hash-bound for it, and its dashboard row shows the same absence across the statement, receipt, and correspondence columns.

## HOL4 statement

### NO HOL STATEMENT YET

No HOL development of the extension theory exists; this node's content is walk structure over baked rows.

## HOL verifier receipts

### NONE

no HOL verification receipt exists for this rule.

## Proof

Genre: core rule (tier 1), the plated-transfer genus (causal-depth face), profile-gated from birth. This section states the rule's soundness obligation exactly, gate included; the rule's schema and walk are baked in the extension theory (rows quoted in this section), and the discharge below is the named obligation of the mechanization column.

**Soundness obligation (depth induction at the discrete-unfolding profile).** At the gated profile (every covered row carrying the one period  $d$  as its dwell parameter — demonic and forced wings admitted, carved wings at floor equal to ceiling  $d$ ; the subject declared at the round-indexed step reading, firings at round  $r$  reading the round- $r$  marking and producing into round  $r + 1$ , rounds at times  $r \cdot d$ ; cited plates' token colors static between firings), by induction over rounds: unit lineage makes each token's production history a path through covered firings; the bracket rows on the negated depth dictionary — every one of the pathwise deterministic-reset species — pin each chain firing's depth advance to exactly one (the gap row bounds the advance from below, the drop-at-most row from above — both sides load-bearing); initial depth is at most zero, universally over the declared initial marking's tokens (vacuous when empty), by the walk's recomputation. Hence a token present at round  $m$  arose through at most  $m$  chain firings in strictly increasing rounds and has declared depth at most  $m$  — so plates of declared depth at least  $k$  ( $k \geq 1$ ) are empty at rounds  $0, \dots, k - 1$ : emptiness at every time  $t \leq T$  for the pinned horizon  $T < k \cdot d$ , surely. The endpoint is strict by construction — the induction permits a depth- $k$  token in the round- $k$  marking itself, so the inclusive horizon  $k \cdot d$  is deliberately not concluded.

**The gate, exactly.** Beyond the profile, per-token chain spacing is NOT a consequence of the per-transition meter law when tokens share a guard: a transition's accrued dwell can be spent on a freshly produced token, collapsing the chain's temporal spacing to one dwell for arbitrarily many chain steps. This is the classical timed-Petri-net memory-policy fork (single-server versus per-token timers); the continuous-time lift is a semantics decision the proposal prices without baking, and the rule refuses outside the profile rather than concluding from an unproven spacing premise.

*Remark R90.1 (status).* The schema is baked: the node, its walk, and its structural side-conditions are landed theory rows (quoted in this section). No Lean statement binds the node yet. A worked instance of the discrete induction (a fabrication-line model with a 370-deep production chain) is already kernel-checked; the named obligation generalizes it to the profile rule.

## 15.11 Distance Transport

### Rule 91. QCOUPLEDRIFT (core rule)

#### The rule (Steele metanotation)

as realized in the mechanized development; source row: QTSL-rules.toml — *QCoupleDrift*. The metanotation statement is typeset by hand for notational quality; its mechanized ground truth is the Lean statement below, extracted from the sources at every build of this book and hash-bound. The rule *roster* is machine-checked (every mechanized rule tag round-trips to exactly one catalogue row); the statement *text* is editorial, checked by eye against the extracted Lean beside it.

$$\begin{array}{l}
 \{ \vdash K(p, \cdot) \geq 0, \sum_q K(p, q) = 1, \pi_{i\#} K(p, \cdot) = \hat{K}_i(p_i, \cdot) \} \text{ (coupling rows, exact } \mathbb{Q}; \hat{K}_i \text{ the completed component kernels)} \\
 \{ \vdash K(p, p) = 1 \text{ for both-absorbed } p \} \text{ (freeze rows)} \\
 \{ \vdash \sum_q K(p, q) V(q) \leq V(p) \} \text{ (relational supermartingale generator row, every product state)} \\
 \vdash V \geq 0 \quad \{ \vdash V \geq 1 \text{ (disagreeing), resp. } V \geq |v_1 - v_2|, \text{ on both-absorbed states} \} \text{ (terminal domination)} \\
 \text{absorption: per-component reach criterion; } \mu_0 \text{ a probability law with } \pi_{i\#} \mu_0 = \text{the component initial laws (initial marginal rows); } \vdash \sum_p \\
 \hline
 \text{QDist}[d](\mathcal{M}_1, \mathcal{M}_2) \leq b \quad d \in \{\text{TV, gap-pseudometrics}\}
 \end{array}$$

the coupling marginals are tied to the *completed* component kernels  $\hat{K}_i$  (absorbing states frozen — the completion carries the component freezes), and the absorption criterion is recomputed by the checker (a per-component graph reach). Coupling emptiness refuses, never lies; the  $\mathbb{W}_1$  registry entry and the mixture-polynomial tier are designed, not yet realized — the finite-chain tier above is the proven fragment.

QCOUPLEDRIFT is the coupling-witnessed discharge of the distance judgment: from a certified coupling of two absorbing Markov chains and a relational supermartingale on the product, it concludes a bound on how far the two systems' final readouts can differ — total-variation distance of the final readout laws, or the gap of final expected values. A producer reaches for it to compare two models of the same system (a nominal chain against a faulted one, a fine model against a simplification): the producer chooses a coupling — a product-space kernel whose marginals are the two chains — that keeps the pair together where the chains agree, and a nonnegative function  $V$  that decreases along the coupled dynamics and dominates the disagreement indicator at absorption. The certified bound is  $V$ 's initial expectation.

What the checker recomputes, all in exact rational arithmetic: that the coupling rows form a genuine kernel (entrywise nonnegative, unit row sums) whose row marginals are exactly the two completed component kernels; that both-absorbed states are frozen; the drift inequality  $\sum_q K(p, q) V(q) \leq V(p)$  at every product state; nonnegativity of  $V$ ; the terminal-domination rows ( $V \geq 1$  on disagreeing both-absorbed states for the total-variation form,  $V \geq |v_1 - v_2|$  for the expectation-gap form); the per-component absorption criterion as a finite-graph reachability check; and the initial bound  $\sum_p \mu_0(p) V(p) \leq b$ .

Each hypothesis is load-bearing, and the proof section walks the omission counterexamples: broken marginals sever the product chain from the systems being compared; without nonnegativity the drift induction cannot be localized to the absorbing set; without terminal domination the coupling inequality has nothing to consume; without absorption the final pair law is not a coupling of the final component laws (mass that never both-absorbs escapes the accounting). A coupling that cannot be completed refuses — the coupling is an input premise, so when none exists no certificate can be formed: the rule never lies by emptiness.

**notes** The judgment-primary form ( $\text{QDist}[d] \leq \varepsilon$ , one conclusion per certificate) deliberately differs from pre/post-style relational program logics [116]: it composes at judgment level (triangle, weaken, symmetry where flagged), and expectation-gap readouts enter as gap-pseudometric registry entries rather than as a second judgment form. The proven fragment is the finite-chain certificate tier, and its conclusion now reads in general vocabulary: the certified bound dominates the Jordan-decomposition total-variation distance of the final readout laws as measures (see the width note); the mixture-polynomial tier and the  $\mathbb{W}_1$  registry entry are designed, not yet realized. A pilot study ran four exact-rational certificates against an independent checker with a mutation battery; on correlated faulting the relational route certified a total-variation bound roughly three times tighter than the best single-chain route — the reason the tier exists.

#### Lean statement

BernsteinLogicAux.TvDist.exists\_hahn

statement bound

```

/-- **The Hahn-set bridge**: for finite measures of equal total mass there
is a measurable set `i` on which the difference attains `tvDist`, and which
dominates the difference on every measurable set. This is the single lemma
through which all Jordan-decomposition bookkeeping flows; everything
downstream (metric axioms, coupling inequality, finite-tier seam) consumes
only its statement. -/
theorem exists_hahn (μ ν : Measure X) [IsFiniteMeasure μ] [IsFiniteMeasure ν]

```

```
(hmass :  $\mu$ .real univ =  $v$ .real univ) :
 $\exists i : \text{Set } X, \text{MeasurableSet } i \wedge \mu.\text{real } i - v.\text{real } i = \text{tvDist } \mu v \wedge$ 
 $\forall A : \text{Set } X, \text{MeasurableSet } A \rightarrow \mu.\text{real } A - v.\text{real } A \leq \mu.\text{real } i - v.\text{real } i$ 
```

## BernsteinLogicAux.TvDist . tvDist\_le\_coupling

statement bound

```
-- **The coupling inequality**: if  $\pi$  on  $X \times X$  has marginals  $\mu$  and
 $v$ , then  $d_{\text{TV}}(\mu, v) \leq \pi \{r \mid r.1 \neq r.2\}$ . The off-diagonal is evaluated by
the *outer* measure, so no measurability of the diagonal (and no separation
hypothesis on  $X$ ) is needed; the marginal conditions themselves force the
total masses to agree. -/
theorem tvDist_le_coupling { $\mu v : \text{Measure } X$ } [IsFiniteMeasure  $\mu$ ] [IsFiniteMeasure  $v$ ]
( $\pi : \text{Measure } (X \times X)$ ) (h $\pi_1 : \pi.\text{map Prod.fst} = \mu$ ) (h $\pi_2 : \pi.\text{map Prod.snd} = v$ ) :
tvDist  $\mu v \leq (\pi \{r : X \times X \mid r.1 \neq r.2\}).\text{toReal}$ 
```

## BernsteinLogicAux.TvDist . tvDist\_ofFn

statement bound

```
-- **The finite-tier compatibility lemma**: on a finite discrete space the
general TV distance of the induced measures is the checker's own
 $(1/2) \cdot L^1$  total variation. Requires only nonnegativity and equal totals
(sub-probability pairs of equal mass included). -/
theorem tvDist_ofFn { $p q : L \rightarrow \mathbb{R}$ } (h $p_0 : \forall l, 0 \leq p l$ ) (h $q_0 : \forall l, 0 \leq q l$ )
(h $\text{tot} : \sum l, p l = \sum l, q l$ ) :

## Correspondence (Steele display $\leftrightarrow$ Lean)

reviewer-certified against the displayed texts

The dictionary below is a reviewer-certified statement of how the mechanized statements above interpret the displayed rule: display metavariable  $\mapsto$  Lean binder, each display hypothesis  $\mapsto$  the premise or side condition carrying it, the display conclusion  $\mapsto$  the goal — with any deliberate difference in width between display and mechanization named outright. Certification is recorded as a hash triple over (the displayed cell, the extracted statement texts, this dictionary's own text); if any of the three changes, this block turns amber until a reviewer re-certifies. The correspondence claim itself remains editorial — reviewer-grade, not machine-checked; its machine-checked successor types each soundness statement against the rule as a structured object, and supersedes this block per rule as it lands.

The displayed  $d \in \{\text{TV, gap-pseudometrics}\}$  is two theorems:  $\text{QDist}[\text{TV}](\mathcal{M}_1, \mathcal{M}_2) \leq b \mapsto \text{sound\_QRelTV}$ 's goal  $\text{tvDist } (\text{push } f (\text{finalLaw } K_1 \dots)) (\text{push } g (\text{finalLaw } K_2 \dots)) \leq b$  — the true total-variation distance of the two final *readout* laws (the readout maps  $f/g$  are the displayed pseudometric's observation structure, explicit in the binder) — and the gap form  $\mapsto \text{sound\_QRelExpGap}$ 's absolute-difference goal. The obligation roster C1–C9 maps row family by row family:

- coupling rows  $\mapsto hK : \text{IsMarkov } K$  (entrywise nonneg, unit sums) +  $hm_1/hm_2$  ( $\text{PushKernel Prod.fst/snd } K K_i$  — marginals equal the completed component kernels, both faces).
- freeze rows  $\mapsto hfreeze$  (both-absorbed diagonal = 1) +  $hfr_1/hfr_2$  (component freezes).
- generator row  $\mapsto hdrift : \forall p, \sum q, K p q * V q \leq V p$ , every product state, displayed vocabulary carried exactly;  $V \geq 0 \mapsto hV0$ .
- terminal domination  $\mapsto hterm$ , per distance flavour, exactly as displayed: the indicator form ( $f p.1 \neq g p.2 \rightarrow 1 \leq V p$ ) and the gap form ( $|v_1 p.1 - v_2 p.2| \leq V p$ ), both on both-absorbed states only.
- the absorption criterion carries this entry's one representation delta: the display asks the per-component reach criterion (recomputed, per the flavor text); the BOUND statements consume absorption in *semantic* form —  $habs_1/habs_2$ , absorbed mass tending to one. The `_of_reach` variants consuming the checker's own graph criterion (via `tendsto_absorbedMass_one`) exist in the module and are cited by the roster witness, but are not in this bound set — machine-checked and cited, not bound, in this edition.

- initial marginal rows  $\mapsto$  carried *by construction*: the component initial laws in the goal ARE push Prod.fst/snd  $\mu_0$  — no separate hypothesis exists because the statement never admits mismatched initials;  $\vdash \sum_p \mu_0(p)V(p) \leq b \mapsto hb$ .

Width note: the *conclusion* is the general object — `TV.sound_QRelTV_measure` (module `BernsteinLogicAux.TvDist`) restates `sound_QRelTV`'s bound against the Jordan-decomposition total-variation distance of the final readout laws viewed as measures, with zero new hypotheses, through the general coupling inequality (`tvDist_le_coupling`: any coupling, off-diagonal weighed by outer measure, no diagonal-measurability assumption) and the finite-tier seam `tvDist_ofFn` (`QRelChain.tvDist` is the general distance restricted); TV is packaged as a metric on probability measures (`TVProb`). The conditional mark therefore re-scopes to the certificate-arithmetic tier: `FIntype` chains with exact real arithmetic standing in for exact  $\mathbb{Q}$  — a fragment fence, by design. The countable tier now carries kernel-level twins (`BernsteinLogicAux.CountableTier`: the drift-induction reach bound, the optional-stopping reach lower bound, and geometric absorption, over `Countable` state spaces with row hypotheses as `tsum` series, summability supplied by the unit-row-sum and boundedness rows), machine-checked and cited, not bound, like the `_of_reach` variants — the  $\mathbb{W}_1$  registry entry and the mixture-polynomial tier remain designed, not realized, exactly as the flavor text says; coupling emptiness has no Lean face because the theorems consume a supplied coupling — refusal-shaped completeness cost lives producer-side.

## Lean verifier receipts

module `BernsteinLogicAux.TvDist`; bound build 54f7e48568aa... (bound from receipt 1c592f5cc199fad5, 2026-07-24T09:28:46Z). A receipt records that named checking layers accepted a build: (module, compiled-artifact SHA-256, environment SHA-256, checker layers), minted when the checking gate ran; the store receipts attesting the bound build are listed with the layers each run credited. Nothing here asks the reader to trust the store: every layer is an independently runnable program over the quoted sources — rebuild the module and re-run the checkers to reproduce the verdict. Receipts attesting superseded builds credit no layer and are omitted from this rendering (the count of omissions, if any, is noted below).

- replay (leanchecker (official kernel replay)) current
- hardened (safe\_verify (hardened screen)) current
- decorrelated (lean4export + nanoda (decorrelated kernel)) current

comparator: none no fixture in the three-implementation comparator harness (compiled / kernel-interpreted / reference-interpreted) exercises this rule.

## HOL4 statement

### NO HOL STATEMENT YET

The HOL4 development checks the base calculus's wire format (theory `bern_catalogue`, the first-order check-function cone of the core catalogue). `QCOUPLEDRIFT` concludes a distance judgment of the extension theory: its rule sort is out of scope of the current baked theory, and the soundness spine lives in the auxiliary Lean package. Nothing exists yet for a HOL statement to be about; the box becomes writable when a revision carries the relational certificate rows and its checker chain is ported.

## HOL verifier receipts

### NONE

no HOL verification receipt exists for this rule.

## Proof

Genre: core rule (tier 1). Scope, stated loudly: the finite-chain tier — finite state spaces, distribution-evolution semantics, exact-rational certificate data instantiated over  $\mathbb{R}$  by cast. The mixture-polynomial tier and the  $\mathbb{W}_1$  conclusion family are designed, not proven, and nothing below claims them. Every hypothesis of the rule is used and remarked on.

**Setting and claim.** Two finite chains are compared: state spaces  $\sigma_1, \sigma_2$ , row-stochastic kernels  $K_1, K_2$ , absorbing target sets  $A_i$  (each  $a \in A_i$  frozen:  $K_i(a, a) = 1$ ), and readouts  $f : \sigma_1 \rightarrow L, g : \sigma_2 \rightarrow L$  (resp. values  $v_1, v_2 : \sigma_i \rightarrow \mathbb{R}$ ). The certificate supplies a *coupling* kernel  $K$  on  $\sigma_1 \times \sigma_2$  with initial law  $\mu_0$ , and a function  $V \geq 0$  with bound  $b$ . The chain's law evolves by  $\mu_{n+1}(t) = \sum_s \mu_n(s) K(s, t)$ ; the *final law* of an absorbing state is its monotone limit mass  $\text{fin}(a) = \sup_n \mu_n(a)$ . Hypotheses (the checker's obligation list, in the order the proof consumes them): the coupling rows make  $K$  a kernel whose row marginals are exactly  $K_1, K_2$  (*marginal identities*); both-absorbed states  $A_1 \times A_2$  are frozen;  $V$  is a supermartingale for  $K$  ( $\sum_q K(p, q) V(q) \leq V(p)$ , every  $p$ );  $V \geq 0$ ; terminal domination ( $V(p) \geq 1$  on both-absorbed  $p$  with  $f(p_1) \neq g(p_2)$ , resp.  $V(p) \geq |v_1(p_1) - v_2(p_2)|$ ); each component chain absorbs almost surely (certified by a finite-graph reach criterion); and  $\sum_p \mu_0(p) V(p) \leq b$ . The claims (`sound_QReLTV`, `sound_QReLExpGap`): the total-variation distance of the two final readout laws, resp. the gap of final expected values, is at most  $b$ .

**Lemma R91.1** (marginal-process lemma). *If every row of  $K$  pushes along  $\pi_i$  to the corresponding row of  $K_i$ , then at every time  $n$  the pushforward of the coupled law is the component law:  $\pi_{i\#} \mu_n = \text{law}_i(n)$ , where  $\text{law}_i$  evolves  $\pi_{i\#} \mu_0$  under  $K_i$ .*

*Proof.* Induction on  $n$ ; the base is definitional. For the step it suffices that the row identities intertwine the two Markov operators:

$$(\pi_{\#} \text{step}_K \mu)(c) = \sum_{\pi(t)=c} \sum_s \mu(s) K(s, t) = \sum_s \mu(s) \sum_{\pi(t)=c} K(s, t) = \sum_s \mu(s) K_i(\pi(s), c) = (\text{step}_{K_i} \pi_{\#} \mu)(c),$$

where the third equality is the pushed-row identity at  $s$  and the last regroupes the outer sum over the fibres of  $\pi$ . This is the coupling's first duty: the product chain really is a joint presentation of the two systems being compared.  $\square$

**Lemma R91.2** (supermartingale induction).  $\sum_p \mu_n(p) V(p) \leq \sum_p \mu_0(p) V(p)$  for all  $n$ .

*Proof.* One step:  $\sum_t (\text{step } \mu)(t) V(t) = \sum_s \mu(s) \sum_t K(s, t) V(t) \leq \sum_s \mu(s) V(s)$ , using the generator row at each  $s$  and  $\mu(s) \geq 0$ . Iterate.  $\square$

**Lemma R91.3** (the finite optional-stopping bound). *Let  $A \subseteq \text{states}$  be frozen, and let  $0 \leq \gamma \leq V$  on  $A$ . Then  $\sum_{a \in A} \text{fin}(a) \gamma(a) \leq b$ .*

*Proof.* At every finite time,

$$\sum_{a \in A} \mu_n(a) \gamma(a) \leq \sum_{a \in A} \mu_n(a) V(a) \leq \sum_{\text{all } s} \mu_n(s) V(s) \leq b,$$

the middle step because  $V \geq 0$  lets the sum extend off  $A$ , the last by Lemma R91.2 and the initial bound. Frozen states have monotone mass ( $\mu_{n+1}(a) \geq \mu_n(a) K(a, a) = \mu_n(a)$ ), so each term converges upward to  $\text{fin}(a) \gamma(a)$ ; the limit of the finite sum obeys the uniform bound. This is optional stopping with monotone convergence of finite sums doing Fatou's work — no measure theory enters at this tier.  $\square$

**Lemma R91.4** (coupling inequality). *For any nonnegative weight  $\gamma$  on  $\sigma_1 \times \sigma_2$ ,*

$$\text{TV}((f \circ \pi_1)_{\#} \gamma, (g \circ \pi_2)_{\#} \gamma) \leq \gamma\{p : f(p_1) \neq g(p_2)\}.$$

*Proof.* Fix a label  $l$ . Splitting each pushed mass over the agreement region  $\{f = g\}$  and its complement, the agreement contributions to the two sides are *equal* (there,  $f(p_1) = l \iff g(p_2) = l$ ), so

$$|(f \pi_1)_{\#} \gamma(l) - (g \pi_2)_{\#} \gamma(l)| \leq \gamma\{f \neq g, f(p_1) = l\} + \gamma\{f \neq g, g(p_2) = l\}.$$

Summing over  $l$  counts the disagreement mass twice, and  $\text{TV} = \frac{1}{2} \sum_l |\cdot|$  halves it. This is the classical coupling lemma [166, §I.2], in Doeblin's tradition [63]; stated for arbitrary nonnegative  $\gamma$  because normalization is never consumed — Step 2 of the theorem applies it to the final pair law, whose unit mass Lemma R91.5 supplies separately.  $\square$

**Lemma R91.5** (final marginal identities). *Suppose additionally each component chain absorbs almost surely (its absorbed mass tends to 1). Then for  $a_1 \in A_1$ :  $\sum_{a_2 \in A_2} \text{fin}_K(a_1, a_2) = \text{fin}_{K_1}(a_1)$ , and symmetrically. Consequently the final pair law on  $A_1 \times A_2$  is a genuine coupling of the two final component laws, of total mass 1.*

*Proof.* Let  $S_n = \sum_{a_2 \in A_2} \mu_n(a_1, a_2)$  and  $T_n = \sum_{s_2} \mu_n(a_1, s_2)$ ; by Lemma R91.1,  $T_n$  is the component-1 law at  $a_1$ . Then  $S_n \leq T_n$ , and

$$T_n - S_n = \sum_{s_2 \notin A_2} \mu_n(a_1, s_2) \leq \sum_{s_2 \notin A_2} (\pi_{2\#} \mu_n)(s_2) = 1 - (\text{component-2 absorbed mass at } n) \rightarrow 0 :$$

the *one-absorbed-loner* mass — pairs whose first coordinate has frozen while the second still wanders — is dominated by the second chain’s unabsorbed mass, which its absorption hypothesis kills. Squeeze; both-absorbed pairs are frozen, so  $S_n$  also converges to the final pair mass. Total mass 1 follows by summing over  $A_1$  and applying component-1 absorption.  $\square$

**Theorem R91.6** (soundness, total-variation form). *Under all hypotheses,  $\text{TV}(f_{\#} \text{fin}_{K_1}, g_{\#} \text{fin}_{K_2}) \leq b$ .*

*Proof.* *Step 1.* By Lemma R91.5 the final pair law  $\gamma$  on  $A_1 \times A_2$  has marginals  $\text{fin}_{K_1}, \text{fin}_{K_2}$ , so the two final readout laws are the two pushforwards of the single weight  $\gamma$ . *Step 2.* Lemma R91.4 bounds their total-variation distance by  $\gamma$ ’s disagreement mass. *Step 3.* Terminal domination says the disagreement indicator is  $\leq V$  on the frozen set  $A_1 \times A_2$  (and  $\geq 0$  everywhere), so Lemma R91.3 with  $\gamma = 1[f \neq g]$  bounds the disagreement mass by  $b$ .  $\square$

**Theorem R91.7** (soundness, expectation-gap form). *With terminal domination in the form  $V(p) \geq |v_1(p_1) - v_2(p_2)|$  on  $A_1 \times A_2$ ,*

$$\left| \sum_{a_1} \text{fin}_{K_1}(a_1) v_1(a_1) - \sum_{a_2} \text{fin}_{K_2}(a_2) v_2(a_2) \right| \leq b.$$

*Proof.* Rewrite both final expectations over the final pair law via Lemma R91.5; the difference becomes  $\sum_p \text{fin}_K(p) (v_1(p_1) - v_2(p_2))$  over  $A_1 \times A_2$ . The triangle inequality moves the absolute value inside, and Lemma R91.3 with  $\gamma = |v_1 - v_2|$  closes. The coupling lemma is not consumed here — domination of the value gap replaces domination of the disagreement indicator; two conclusion families, one engine.  $\square$

**Remark R91.8** (the absorption criterion is discharged, not assumed). The checker certifies absorption per component as a finite-graph fact: from every state, the frozen set is reachable through positive-probability edges. Finiteness uniformizes this into one horizon  $N$  and one margin  $\varepsilon > 0$  valid for all states; each  $N$ -step block then absorbs at least an  $\varepsilon$ -fraction of the still-loose mass (frozen mass never returns), so the unabsorbed mass decays geometrically and the absorbed mass tends to 1 (`tendsto_absorbedMass_one`). The `_of_reach` theorem forms consume the graph criterion directly.

**Remark R91.9** (why each hypothesis is needed). *Marginal identities:* drop them and  $\gamma$  in Theorem R91.6 no longer has the two systems’ final laws as marginals — the bound then constrains an unrelated pair (couple  $\mathcal{M}_1$  with a copy of *itself* instead of  $\mathcal{M}_2$ : every absorbed pair agrees, so  $V = 0$  on the reachable diagonal — with  $V = 1$  on the unreachable disagreeing absorbed pairs — passes every other row at  $b = 0$ , whatever  $\mathcal{M}_2$  is).  $V \geq 0$ : the extension step in Lemma R91.3 ( $\sum_A \leq \sum_{\text{all}}$ ) fails, and negative values can subsidize the generator row: from an initial state of value 0, branch half-half into a frozen *disagreeing* state of value 1 and a frozen *agreeing* state of value  $-1$  (domination constrains only disagreeing states). The generator row holds at every state ( $\frac{1}{2} \cdot 1 + \frac{1}{2} \cdot (-1) = 0 \leq 0$ ), the initial bound passes at  $b = 0$  — and the disagreement mass is  $\frac{1}{2}$ . *Terminal domination:* with  $V \equiv 0$  and disagreeing finals, generator and initial rows pass at  $b = 0$  while the true distance is 1. *The freeze:* monotone convergence of frozen mass (Lemmas R91.3, R91.5) is what makes “final law” well-defined; unfrozen, the two-state swap chain puts mass 1 on the target at even times and 0 at odd —  $\sup_n \mu_n(a)$  is no longer a limit, and certified mass drains back out. *Absorption:* without it the one-absorbed-loner mass survives — take  $K_2$  the identity off  $A_2$ : the pair never both-absorbs, the final pair law is 0, and Lemma R91.4 holds vacuously about sub-laws that no longer represent the systems; the marginal identity of Lemma R91.5 is exactly what fails — and the bound itself fails with it: component 1 absorbing at once, component 2 frozen nowhere it reaches,  $V = 0$  on the reachable ray and 1 on the (unreachable) disagreeing both-absorbed pairs passes every other row at  $b = 0$ , while the final readout laws sit at total-variation distance  $\frac{1}{2}$ . *Initial bound:* the conclusion’s  $b$  is  $V$ ’s initial expectation; without it nothing quantitative survives. A coupling that cannot satisfy the marginal rows simply does not exist as a certificate — the coupling is an input premise, so its emptiness refuses (a completeness cost), never lies.

**Remark R91.10** (relation to the literature). The engine is the coupling method for Markov chains [63, 166]: total variation bounded by disagreement probability of a coupling, here in distribution-evolution form over finite spaces [160, Ch. 4–5], with a relational supermartingale supplying the quantitative disagreement bound — the certificate-side sibling of coupling-based relational program logics [116], transposed from pre/post judgments to a single distance judgment that composes by metric axioms (triangle, weakening) at judgment level. The expectation-gap form replaces the coupling lemma by direct domination — the gap-pseudometric readout. On correlated perturbations the relational route is strictly sharper than composing two one-sided certificates, which is the rule’s reason to exist: the coupling sees the correlation, unary certificates cannot.

## Rule 92. QFixBall (core rule)

### The rule (Steele metanotation)

as realized in the mechanized development; source row: `QTSL-rules.toml` — *QFixBall*. The metanotation statement is typeset by hand for notational quality; its mechanized ground truth is the Lean statement below, extracted from the sources at every build of this book and hash-bound. The rule *roster* is machine-checked (every mechanized rule tag round-trips to exactly one catalogue row); the statement *text* is editorial, checked by eye against the extracted Lean beside it.

$$\frac{\begin{array}{l} d : \text{QDistRegistry}(X_d); \quad (X_d, d) \text{ complete} \quad \vdash \rho < 1 \text{ two-point on } \overline{B}(\hat{\mu}, r) \text{ (contraction row)} \\ \vdash d(T\hat{\mu}, \hat{\mu}) \leq \delta \text{ (residual row)} \quad \vdash \delta + \rho r \leq r \text{ (radius row, division-free)} \end{array}}{\vdash \text{QDist}[d](\hat{\mu}, \text{fix } T) \leq r}$$

every hypothesis anchored at the known snapshot  $\hat{\mu}$ , never at the unknown fixed point: the contraction row discharges by operator-norm/psdCert rows at the affine tier, the residual row is one concrete sweep at the known point, and completeness is mechanized at the affine/Euclidean instantiation ( $\mathbb{W}_2$  completeness by instance on  $(\mathcal{P}_2(X), W_2)$ ). The conclusion's definite description needs no separate license premise: this rule is the only derivation that makes  $\text{fix } T$  speakable, and it discharges the description's well-formedness itself — exactly one fixed point exists in  $\overline{B}(\hat{\mu}, r)$ , manufactured by the contraction (the  $\exists!$  of the soundness statement; no existence stratum consumed). The registry typing has no baked sort yet (the promoted QDist kind awaits its row species); completeness is the instance hypothesis of the Lean statement. Refusals:  $\rho \geq 1$ , and registry entries the subject sort does not carry.

QFixBall is the contraction-witnessed discharge of the distance judgment: it certifies that a computed snapshot  $\hat{\mu}$  lies within distance  $r$  of the fixed point of an update map  $T$  — and, in the same breath, that “the fixed point of  $T$ ” is a well-defined description at all (exactly one fixed point exists in the certified ball). A producer reaches for it wherever an iterative solver has been run to approximate a fixed-point object — a stationary law, a variational posterior, a self-consistent field — and the deliverable is not the iterate but a certified *ball* around it. Its three rows realize the anchoring inversion: every hypothesis is stated at the *known* snapshot, never at the unknown fixed point — the contraction row bounds  $T$ 's two-point ratio on the closed ball around  $\hat{\mu}$ , the residual row measures one concrete application  $d(T\hat{\mu}, \hat{\mu}) \leq \delta$ , and the radius row  $\delta + \rho r \leq r$  is division-free arithmetic.

What the checker recomputes: the contraction bound  $\rho < 1$  (at the affine tier, an operator-norm row discharged by positive-semidefinite certificate machinery on  $\rho^2 I - A^\top A$ -shaped data), the residual evaluation (one sweep of the map at the snapshot, exact rational arithmetic), and the radius inequality. Everything else — ball self-mapping, existence, uniqueness, the anchored bound  $d(\hat{\mu}, \text{fix } T) \leq \delta/(1 - \rho) \leq r$  — is manufactured by the mathematics from those three rows; no existence stratum is consumed, so the judgment is existential without vacuity.

What would break: with  $\rho \geq 1$  the fixed point need not be unique or exist and the description license fails — the rule refuses (the identity map has residual 0 at every point and fixes all of them). Without the radius row the ball need not be self-mapped and can miss the fixed point entirely, even with a genuine contraction. Without the residual row nothing ties the ball to the dynamics. The completeness of the subject space is a genuine hypothesis, carried honestly — and both named instantiations now discharge it by instance: the affine/Euclidean case directly, and the Wasserstein case on  $(\mathcal{P}_2(X), W_2)$  over a complete separable base (the instantiation block below) — never an axiom smuggled in.

**notes** The rule concludes onto a definite-description subject ( $\text{fix } T$ ) and therefore carries the description well-formedness discharge inside the rule — the one new typing obligation of the distance-judgment grammar. An independent exact-arithmetic checker replays a pilot certificate's eleven obligations; its mutation battery refuses each mutilated certificate at a named obligation. Producer strategy (proposing  $\rho$  from iterate data, pinning the affine reduction) is deliberately outside the kernel.

### Lean statement

BernsteinLogicAux.QFixBall . sound\_QFixBall

statement bound

```
-- **`sound_QFixBall`** -- the rule's full conclusion: the certified
rows produce EXACTLY ONE fixed point of `f` in `closedBall x₀ r`.
Existence is manufactured by the contraction itself (the third case of
the two-direction carve: no existence stratum is consumed, and the
judgment is existential without vacuity). `[CompleteSpace α]` is the
honest boundary – see the header. -/
theorem sound_QFixBall [CompleteSpace α] (hK : K < 1)
  (hLip : LipschitzOnWith K f (closedBall x₀ r))
  (hres : dist (f x₀) x₀ ≤ δ) (hrad : δ + K * r ≤ r) :
  ∃! y, y ∈ closedBall x₀ r ∧ IsFixedPt f y
```

BernsteinLogicAux.QFixBall . sound\_QFixBall\_affine

statement bound

```

/-- **`sound_QFixBall_affine`** – the caviwball-v0 instantiation shape:
snapshot mean vector in `EuclideanSpace ℝ (Fin M)` (completeness is an
instance – the `[CompleteSpace]` boundary discharges for free here),
affine sweep map, operator-norm + residual + radius rows  $\Rightarrow$  unique
fixed point in the certified ball. -/
theorem sound_QFixBall_affine {M : ℕ}
  (A : EuclideanSpace ℝ (Fin M)  $\rightarrow$  L[ℝ] EuclideanSpace ℝ (Fin M))
  (c x₀ : EuclideanSpace ℝ (Fin M)) {K : ℝ $\geq$ 0} {δ r : ℝ}
  (hK : K < 1) (hA : ||A|| $_+$   $\leq$  K)
  (hres : dist (A x₀ + c) x₀  $\leq$  δ) (hrad : δ + K * r  $\leq$  r) :
   $\exists!$  y, y  $\in$  closedBall x₀ r  $\wedge$  IsFixedPt (fun x  $\Rightarrow$  A x + c) y

```

BernsteinLogicAux.QFixBall. **dist\_fixedPoint\_le**

statement bound

```

/-- **The anchored a-priori bound** – for ANY fixed point in the ball
(uniqueness not consumed): `dist x₀ μ*  $\leq$  δ / (1 - K)`. Proved by one
triangle inequality through the snapshot's image; the literature's
one-point-at-the-limit anchoring never appears. -/
theorem dist_fixedPoint_le (hK : K < 1)
  (hlip : LipschitzOnWith K f (closedBall x₀ r))
  (hres : dist (f x₀) x₀  $\leq$  δ) (hrad : δ + K * r  $\leq$  r)
  {y : α} (hy : y  $\in$  closedBall x₀ r) (hfy : IsFixedPt f y) :
  dist x₀ y  $\leq$  δ / (1 - K)

```

BernsteinLogicAux.QFixBall. **anchored\_le\_radius**

statement bound

```

/-- The radius row also caps the anchored bound by `r` itself
(`δ/(1-K)  $\leq$  r`) – the form the checker's ball-radius obligation uses. -/
theorem anchored_le_radius (hK : K < 1)
  (hrad : δ + K * r  $\leq$  r) : δ / (1 - K)  $\leq$  r

```

**The Wasserstein instantiation, discharged by instance.** The completeness hypothesis named above is closed on the space where this rule's stochastic clients live: the statement below runs `sound_QFixBall` on  $(\mathcal{P}_2(X), W_2)$  — second-moment laws under quadratic Wasserstein distance over a complete separable metric space — with the `CompleteSpace` side condition supplied by instance resolution rather than hypothesis. No completeness assumption survives in the statement; the affine and Wasserstein instantiations now stand on the same footing.

BernsteinLogicAux.Wasserstein.Complete. **sound\_QFixBall\_wasserstein**

statement bound

```

/-- **`sound_QFixBall`**, instantiated at the Wasserstein-2 space.** The
`[CompleteSpace]` hypothesis – the honest boundary of
`BernsteinLogicAux/QFixBall.lean` (header item 1), and the side
condition that kept the rule's coverage marked conditional – is
discharged here **by instance**: for any complete separable metric `X`,
certified contraction/residual/radius rows on  $(\mathcal{P}_2(X), W_2)$  produce
the unique fixed point in the certified ball. -/
theorem sound_QFixBall_wasserstein {T : P2 X  $\rightarrow$  P2 X} {μ₀ : P2 X} {K : ℝ $\geq$ 0}
  {δ r : ℝ} (hK : K < 1)
  (hlip : LipschitzOnWith K T (closedBall μ₀ r))
  (hres : dist (T μ₀) μ₀  $\leq$  δ) (hrad : δ + K * r  $\leq$  r) :
   $\exists!$  ν, ν  $\in$  closedBall μ₀ r  $\wedge$  IsFixedPt T ν

```

## Correspondence (Steele display $\leftrightarrow$ Lean)

reviewer-certified against the displayed texts

The dictionary below is a reviewer-certified statement of how the mechanized statements above interpret the displayed rule: display metavariable  $\mapsto$  Lean binder, each display hypothesis  $\mapsto$  the premise or side condition carrying it, the display conclusion  $\mapsto$  the goal — with any deliberate difference in width between display and mechanization named outright. Certification is recorded as a hash triple over (the displayed cell, the extracted statement texts, this dictionary's own text); if any of the three changes, this block turns amber until a reviewer re-certifies. The correspondence claim itself remains editorial — reviewer-grade, not machine-checked; its machine-checked successor types each soundness statement against the rule as a structured object, and supersedes this block per rule as it lands.

The displayed conclusion splits, and so do the bound statements: the description license — fix  $T$  well-defined (unique) in  $\overline{B}(\hat{\mu}, r)$  —  $\mapsto$  `sound_QFixBall` :  $\exists! y, y \in \text{closedBall } x_0 \ r \wedge \text{IsFixedPt } f \ y$  (existence manufactured by the contraction itself; no existence stratum consumed, exactly as the roster says); the distance clause  $\text{QDist}[d](\hat{\mu}, \text{fix } T) \leq r$  is then ball membership, with the sharper anchored bound  $\delta/(1 - \rho)$  carried by `dist_fixedPoint_le` — whose binder row shows uniqueness is NOT consumed (any fixed point in the ball obeys it) — and capped by the radius row via `anchored_le_radius`.

- contraction row, two-point on the ball  $\mapsto$  hlip : LipschitzOnWith K f (closedBall x<sub>0</sub> r) with K :  $\mathbb{R}_{\geq 0}$ , hK : K < 1 — the  $\rho \geq 1$  refusal is the strict binder; at the affine tier the operator-norm row  $\mapsto$  hA :  $\|A\|_+ \leq K$  in sound\_QFixBall\_affine (EuclideanSpace, the caviwball-v0 pinned mean map).
- residual row  $\mapsto$  hres : dist (f x<sub>0</sub>) x<sub>0</sub> ≤ δ — anchored at the snapshot, and no hypothesis anywhere mentions the fixed point: the flavor text's “never at the unknown fixed point” is a checkable property of the binder list.
- radius row  $\mapsto$  hrad : δ + K \* r ≤ r, division-free verbatim.
- registry completeness  $\mapsto$  the instance binder [CompleteSpace α] — a named hypothesis of the general statement, never an axiom, and discharged by instance resolution in both named instantiations: directly for the affine/Euclidean case, and for  $\mathbb{W}_2$  by the Wasserstein block (sound\_QFixBall\_wasserstein) below.

Width note: the subject space is an arbitrary metric space — the registry-entry structure of  $d$  is erased, so the certified reach covers every registry instantiation whose completeness discharge arrives (both named instantiations' discharges are now in hand), strictly wider than the displayed registry framing, safe direction; the means-only (variance-conclusion) refusal and the Gaussian-pinning producer strategy are kernel-external, no Lean counterpart, correctly.

## Lean verifier receipts

module BernsteinLogicAux.QFixBall; bound build 68796bc2f9db... (bound from receipt 060c7093ff4899bf, 2026-07-21T04:51:42Z). A receipt records that named checking layers accepted a build: (module, compiled-artifact SHA-256, environment SHA-256, checker layers), minted when the checking gate ran; the store receipts attesting the bound build are listed with the layers each run credited. Nothing here asks the reader to trust the store: every layer is an independently runnable program over the quoted sources — rebuild the module and re-run the checkers to reproduce the verdict. Receipts attesting superseded builds credit no layer and are omitted from this rendering (the count of omissions, if any, is noted below).

| receipt          | minted               | layers                             | status  |

4 further receipt(s) in the store attest superseded builds of this module and are omitted from this rendering.

### gate-layer coverage of the bound build:

build (lake build (elaboration)) current

replay (leanchecker (official kernel replay)) current

hardened (safe\_verify (hardened screen)) current

decorrelated (lean4export + nanoda (decorrelated kernel)) current

comparator: none no fixture in the three-implementation comparator harness (compiled / kernel-interpreted / reference-interpreted) exercises this rule.

## HOL4 statement

### NO HOL STATEMENT YET

The HOL4 development's object is the base calculus's wire-format checker (theory `bern_catalogue` ports the first-order check-function cone of the core catalogue). QFIXBALL lives one extension edge above that stratum — it concludes a distance judgment of the extension theory, its rule sort is out of scope of the current baked theory, and its mechanization lives in the auxiliary Lean package. There is nothing checker-shaped for a HOL statement to be about yet; the box becomes writable when a revision of the theory carries the certificate objects and the corresponding checker chain is ported.

## HOL verifier receipts

### NONE

no HOL verification receipt exists for this rule.

## Proof

Genre: core rule (tier 1) — Banach's fixed-point theorem [15] in certificate form. Scope, stated loudly: the theorems are parametric in a complete metric space; the affine/Euclidean instantiation is mechanized, and completeness of the Wasserstein space is a *named hypothesis*, not a discharged one. Every hypothesis of the rule is used below and remarked on.

**Setting and claim.** Fix a metric space  $(X, d)$ , a map  $T : X \rightarrow X$ , a snapshot  $\hat{\mu} \in X$  (the object the producer actually computed), and rational certificate data  $\rho \in \mathbb{Q} \cap [0, 1)$ ,  $\delta, r \in \mathbb{Q}$ . The three certified rows:

$$\begin{array}{ll} \text{(H-ANCHOR)} & d(Tx, Ty) \leq \rho d(x, y) \text{ for all } x, y \in \overline{B}(\hat{\mu}, r) & \text{(two-point contraction on the ball),} \\ \text{(H-RESID)} & d(T\hat{\mu}, \hat{\mu}) \leq \delta & \text{(one concrete sweep at the snapshot),} \\ \text{(H-RADIUS)} & \delta + \rho r \leq r & \text{(division-free; equivalent to } r \geq \delta/(1 - \rho)\text{).} \end{array}$$

The claim (`sound_QFixBall`): if  $X$  is complete, there is *exactly one* fixed point of  $T$  in  $\overline{B}(\hat{\mu}, r)$  — so the description `fix T` is licensed on the ball, and the distance judgment  $d(\hat{\mu}, \text{fix } T) \leq r$  holds; moreover the sharper anchored bound  $d(\hat{\mu}, \text{fix } T) \leq \delta/(1 - \rho)$  holds (`dist_fixedPoint_le, anchored_le_radius`). Every hypothesis is anchored at the *known* point  $\hat{\mu}$ ; the unknown fixed point appears only in conclusions — the anchoring inversion that makes the statement checkable at all.

**Lemma R92.1** (the rows are sign-coherent). *H-RESID forces  $\delta \geq 0$ ; together with  $\rho < 1$ , H-RADIUS forces  $r \geq 0$ , so the ball is honest.*

*Proof.*  $0 \leq d(T\hat{\mu}, \hat{\mu}) \leq \delta$ . From H-RADIUS,  $(1 - \rho)r \geq \delta \geq 0$ , and  $1 - \rho > 0$ . □

**Lemma R92.2** (self-mapping is derived, never assumed). *T maps  $\overline{B}(\hat{\mu}, r)$  into itself.*

*Proof.* Let  $d(x, \hat{\mu}) \leq r$ . Both  $x$  and  $\hat{\mu}$  lie in the ball (Lemma R92.1 for  $\hat{\mu}$ ), so H-ANCHOR applies to the pair:

$$d(Tx, \hat{\mu}) \leq d(Tx, T\hat{\mu}) + d(T\hat{\mu}, \hat{\mu}) \leq \rho d(x, \hat{\mu}) + \delta \leq \rho r + \delta \leq r. \quad \square$$

**Lemma R92.3** (in-ball uniqueness). *If  $y, z \in \overline{B}(\hat{\mu}, r)$  are both fixed by  $T$ , then  $y = z$ .*

*Proof.*  $d(y, z) = d(Ty, Tz) \leq \rho d(y, z)$  with  $\rho < 1$  forces  $d(y, z) \leq 0$ , hence  $= 0$ . Note the proof consumes only the *two-point* row, on the ball — no iteration, no completeness. □

**Lemma R92.4** (the anchored a-priori bound). *Any fixed point  $y \in \overline{B}(\hat{\mu}, r)$  satisfies  $d(\hat{\mu}, y) \leq \delta/(1 - \rho) \leq r$ .*

*Proof.* One triangle inequality through the snapshot's image:

$$d(\hat{\mu}, y) \leq d(\hat{\mu}, T\hat{\mu}) + d(T\hat{\mu}, Ty) \leq \delta + \rho d(\hat{\mu}, y),$$

so  $(1 - \rho)d(\hat{\mu}, y) \leq \delta$ . The cap by  $r$  is H-RADIUS rearranged:  $\delta \leq (1 - \rho)r$  (`anchored_le_radius`). Uniqueness is not consumed — the bound holds for *any* fixed point in the ball, which is what lets the rule state it before existence is settled. □

**Theorem R92.5** (soundness of QFIXBALL). *Let  $X$  be complete and let the three rows hold. Then  $T$  has exactly one fixed point  $\mu^*$  in  $\overline{B}(\hat{\mu}, r)$ , and  $d(\hat{\mu}, \mu^*) \leq \delta/(1 - \rho) \leq r$ .*

*Proof. Existence.* By Lemma R92.2 the closed ball is  $T$ -invariant; it is a closed subset of a complete space, hence complete, and  $T$  restricted to it is a  $\rho$ -contraction (H-ANCHOR). Banach's theorem [15] applies to the restriction: the Picard iterates  $T^n \hat{\mu}$  form a Cauchy sequence ( $d(T^{n+1} \hat{\mu}, T^n \hat{\mu}) \leq \rho^n \delta$ , summable) whose limit  $\mu^*$  lies in the ball and is fixed. Existence is thus *manufactured* by the contraction — the rule consumes no separate existence certificate, so the concluded description is existential without vacuity. *Uniqueness* is Lemma R92.3; the *bound* is Lemma R92.4. Together: `fix T` is well-defined on the ball (the description license the judgment carries) and the distance judgment holds at radius  $r$ , with  $\delta/(1 - \rho)$  as the sharper certified value. □

**Proposition R92.6** (the affine instantiation). *On a finite-dimensional Euclidean space, let  $Tx = Ax + c$  with  $A$  linear and an operator-norm row  $\|A\| \leq \rho < 1$ . Then  $H\text{-ANCHOR}$  holds globally (a fortiori on the ball), completeness holds by instance, and Theorem R92.5 applies verbatim (`sound_QFixBall_affine`).*

*Proof.*  $d(Tx, Ty) = \|A(x - y)\| \leq \|A\| \|x - y\| \leq \rho d(x, y)$ . The operator-norm row is the affine tier’s discharge of  $H\text{-ANCHOR}$ : it is certified by positive-semidefiniteness of  $\rho^2 I - A^\top A$ , which is PSDCERT-family machinery on rational data.  $\square$

*Remark R92.7* (why each hypothesis is needed). *Drop  $\rho < 1$* : the identity map has residual 0 at every snapshot and every radius row holds with  $\rho = 1$ , yet every point is fixed — the description license (uniqueness) fails, so the rule *refuses*  $\rho \geq 1$  rather than concluding. *Drop  $H\text{-RADIUS}$* : on  $\mathbb{R}$ , take  $Tx = \frac{1}{2}x + 2$ ,  $\hat{\mu} = 0$ , so  $\rho = \frac{1}{2}$ ,  $\delta = 2$ ; the unique fixed point is 4. With  $r = 1$  the ball  $[-1, 1]$  contains no fixed point — and indeed  $\delta + \rho r = \frac{5}{2} > 1$ : the radius row fails, correctly. *Drop  $H\text{-RESID}$* : nothing ties the ball to the dynamics — any  $r$  would pass on any map with small  $\rho$ , concluding a distance bound to a fixed point that can sit arbitrarily far away. *Weaken completeness*: on  $X = \mathbb{Q} \cap [1, 2]$  (incomplete),  $Tx = \frac{x}{2} + \frac{1}{x}$  maps  $X$  into itself with  $|T'| \leq \frac{1}{2}$  and contracts toward the irrational  $\sqrt{2}$  — iterates Cauchy, no fixed point in  $X$ , and the certificate rows even pass ( $\hat{\mu} = \frac{3}{2}$ ,  $r = \frac{1}{2}$ ,  $\rho = \frac{1}{2}$ ,  $\delta = \frac{1}{12}$ , with  $\delta + \rho r = \frac{1}{3} \leq \frac{1}{2}$ ); the conclusion’s existential half is exactly what completeness buys. The two-point row being required only *on the ball* is deliberate: locality is what a finite certificate can attest (globally,  $\|A\| < 1$  may even be false while the ball-restricted bound holds).

*Remark R92.8* (relation to the literature). The theorem is Banach’s [15]; the closed-ball variant with the condition  $d(T\hat{\mu}, \hat{\mu}) \leq (1 - \rho)r$  and the a-priori bound  $\delta/(1 - \rho)$  is the textbook local form [99, §I.1]. The certificate-form contribution is the *anchoring inversion*: classical statements estimate the distance from an iterate to the limit; the rule re-expresses every hypothesis as a row checkable at the known snapshot in exact rational arithmetic — contraction as an operator-norm (or two-point) row, residual as one evaluated sweep, radius as division-free arithmetic — so the analytic content survives while everything the checker touches is decidable. The completeness gap for measure-space subjects (Wasserstein distance over a Euclidean base) is carried as a named hypothesis; the pilot certificate discharges it by pinning the subject to the affine/Euclidean reduction of Proposition R92.6.

## Rule 93. QDISTTRANSPORT (core rule)

### The rule (Steele metanotation)

as realized in the mechanized development; source row: QTSL-rules.toml — *QDistTransport*. The metanotation statement is typeset by hand for notational quality; its mechanized ground truth is the Lean statement below, extracted from the sources at every build of this book and hash-bound. The rule *roster* is machine-checked (every mechanized rule tag round-trips to exactly one catalogue row); the statement *text* is editorial, checked by eye against the extracted Lean beside it.

$$\frac{\begin{array}{l} J = (\mathcal{M}_c \models s) \text{ (strict, law-level) } \text{ or } J = (\text{QDist}[\text{TV}](\mu_c, \nu) \leq \delta), \text{ on the coarse side} \\ \{ \vdash \text{tv}(\pi_{\#} K(s, \cdot), Q(\pi(s), \cdot)) \leq \varepsilon \}_{s \in S_f} \text{ (}\sigma\text{-witness rows, one per fine state; } \varepsilon = 0 \text{ is exact intertwining)} \\ \vdash \mu_c^0 = \pi_{\#} \mu_f^0 \text{ (initial row)} \quad n \in \mathbb{N} \text{ (declared horizon; } \varepsilon\text{-cell only)} \end{array}}{\begin{array}{l} \text{exact cell: } J \text{ transports unchanged} \quad \varepsilon\text{-cell: } \text{QDist}[\text{TV}](\pi_{\#}(\text{fine law at } n), \text{ coarse law at } n) \leq n \varepsilon \end{array}}$$

$\pi : S_f \rightarrow S_c$  is the state projection,  $K$  and  $Q$  the fine and coarse kernels,  $\mu^0$  the initial laws; each  $\sigma$ -witness row asserts that one row of the fine kernel pushes along  $\pi$  to within total-variation  $\varepsilon$  of the coarse kernel's row at the projected state. Unbounded horizons refuse without a contraction row. The displayed  $J$  is restricted to the built judgment classes (strict law-level specs and  $\text{QDist}[\text{TV}]$ ); the successor cells widen it as they land. Transport is a matrix (judgment class  $\times$  witness class), each built cell carrying its own lemma and refusal condition; sequential witnesses compose under the certified budget  $\varepsilon_1 + \varepsilon_2$  (an upper bound — the actual composite defect may be smaller), and the strict column is the  $\varepsilon = 0$  instantiation of the family. Built at the finite-kernel tier; the Lipschitz-pushforward ( $\mathbb{W}_p$ ) and description-subject cells are named successors.

**QDISTTRANSPORT** moves judgments across a simulation map. It is a *matrix* of transport cells — judgment class (strict spec vs. distance judgment)  $\times$  witness class (exact intertwining vs.  $\varepsilon$ -approximate intertwining) — each cell carrying its own conclusion form, its own lemma, and its own refusal condition. A producer reaches for it to certify a fine model through a coarse one: prove the spec on the abstraction, exhibit the simulation witness, and transport. The two built kernel-tier cells: under an *exact* witness (every row of the fine kernel pushes along the readout map exactly onto the coarse kernel's row) laws transport unchanged at every horizon, so any judgment about the coarse law pulls back with zero degradation; under an  $\varepsilon$ -witness (every row pushes to within total-variation distance  $\varepsilon$ ) a strict judgment does NOT transport — what transports is a *distance* judgment, with  $\varepsilon$  inherited and horizon-compounded: the pushed fine law tracks the coarse law to  $n \varepsilon$  at declared horizon  $n$ . The degrading cell is what makes approximate simulation a distance-judgment *producer*.

What the checker recomputes: the per-row intertwining identities (exact case) or per-row total-variation defects against the declared  $\varepsilon$  (approximate case), well-formedness of both kernels, and the horizon arithmetic. The compounding law  $n \varepsilon$  is proved, never guessed: one-step defect by mixture convexity, then the coarse Markov operator's total-variation nonexpansiveness (data processing — the coarse chain cannot amplify tracking error), then telescoping. Sequential witnesses compose with certified budget  $\varepsilon_1 + \varepsilon_2$  — an upper bound with no additional bookkeeping slack (plain addition is the honest lattice at this tier), though the composite's actual defect may be smaller.

What would break: without the coarse kernel's row stochasticity the operator could amplify differences and the telescoping collapses; without a genuine probability law at the start, mixture convexity fails; and without a contraction row the linear growth in  $n$  is sharp, which is why the  $\varepsilon$ -cell refuses unbounded horizons rather than extrapolating.

**notes** The strict column is the  $\varepsilon = 0$  instantiation of the family — one biconditional, so the exact cell re-exports the marginal-process lemma rather than restating it. Analytic lineage: approximate (bi)simulation with quantitative degradation [93] and behavioural pseudometrics for probabilistic systems [61]. Built at the finite-kernel tier (the scope the Lean statements carry); the Lipschitz-pushforward cells for  $\mathbb{W}_p$  registry entries, the description-subject cells, and the per-cell composition-coherence squares are named successors.

### Lean statement

BernsteinLogicAux.QDistTransport . sound\_QDistTransport\_eps

statement bound

```
-- **`sound_QDistTransport_eps` — the degrading cell's transport
theorem** (matrix cell: strict judgment  $\times$   $\varepsilon$ -witness  $\Rightarrow$  distance
judgment): at horizon `n`, the pushed fine law and the coarse law are
within TV-distance `n * ε`. Telescoping: one-step defect (`ε`, above) +
TV-nonexpansiveness of the coarse operator (§3) + triangle. This is
the theorem that makes "ε inherited, horizon-compounded" a proved
compounding law rather than a guess; with no contraction row the
linear growth is the honest rate (the refusal condition for unbounded
horizons lives spec-side). -/

Correspondence (Steele display  $\leftrightarrow$  Lean)

**reviewer-certified against the displayed texts** The dictionary below is a reviewer-certified statement of how the mechanized statements above interpret the displayed rule: display metavariable  $\mapsto$  Lean binder, each display hypothesis  $\mapsto$  the premise or side condition carrying it, the display conclusion  $\mapsto$  the goal — with any deliberate difference in width between display and mechanization named outright. Certification is recorded as a hash triple over (the displayed cell, the extracted statement texts, this dictionary's own text); if any of the three changes, this block turns amber until a reviewer re-certifies. The correspondence claim itself remains editorial — reviewer-grade, not machine-checked; its machine-checked successor types each soundness statement against the rule as a structured object, and supersedes this block per rule as it lands.

The display is a matrix and the bound set is its built column, cell by cell. The  $\varepsilon$ -cell's conclusion  $QDist[TV](\text{fine pushed law, coarse law}) \leq n\varepsilon$  at horizon  $n \mapsto \text{sound\_QDistTransport\_eps} : \text{tvDist} (\text{push } \pi (\text{law } K \ \mu_0 \ n)) (\text{law } Q (\text{push } \pi \ \mu_0) \ n) \leq n * \varepsilon$  — the compounding law as a proved induction (one-step defect + TV-nonexpansiveness of the coarse operator + triangle), never a guess.

- the  $\sigma$ -witness rows  $\mapsto$  EpsPushKernel  $\pi \ K \ Q \ \varepsilon$  (every fine row pushes to within TV  $\varepsilon$  of the coarse row at the projected state), with the exact-intertwining column certified as its  $\varepsilon = 0$  face: pushKernel\_iff\_eps\_zero, and the strict cell strict\_cell\_exact re-exporting push\_law — laws transport *exactly* at every horizon, zero degradation.
- the initial row (coarse initial law =  $\pi_{\#}$  fine initial)  $\mapsto$  carried by construction: the coarse arguments in every goal ARE push  $\pi \ \mu_0$  — mismatched initials are unrepresentable in the statement, so no hypothesis row exists.
- the declared horizon  $\mapsto$  the explicit  $n : \mathbb{N}$  binder; the refusal condition for unbounded horizons without a contraction row is spec-side with no Lean counterpart — the honest linear rate IS the certified statement.
- sequential accumulation  $\mapsto$  epsPushKernel\_comp: certified composite budget  $\varepsilon_1 + \varepsilon_2$ , plain addition as the displayed lattice — an upper bound (the actual composite defect may be smaller); the distance-judgment  $\times$  strict-witness cell  $\mapsto$  sound\_QDistSelfTransport (TV data processing at  $L = 1$ ).

- consumed regularity: the  $\varepsilon$ -cell alone demands well-formedness (IsMarkov both kernels, IsDist  $\mu_0$ ) — the mixture-convexity and nonexpansiveness steps use it — while the strict cell and the composition law are hypothesis-free beyond their witnesses: visible in the binder rows.

Width note: finite-kernel tier (Fintype, DecidableEq for fibre sums), as the flavor text confines it; the unbuilt cells ( $\mathbb{W}_p$  Lipschitz pushforward, description subjects, per-cell coherence squares) are the conditional residue, named in the note, bound by nothing — and the judgment-class abstraction of the display's  $J$  ("or a strict spec") is realized concretely: strict specs ride `strict_cell_exact`, distance judgments ride the TV theorems; no single parameterized  $J$  exists in Lean, the matrix's rows are separate theorems.

## Lean verifier receipts

module BernsteinLogicAux.QDistTransport; bound build 4bd1c5103f38... (bound from receipt 6ff1345414960d8f, 2026-07-21T05:38:55Z). A receipt records that named checking layers accepted a build: (module, compiled-artifact SHA-256, environment SHA-256, checker layers), minted when the checking gate ran; the store receipts attesting the bound build are listed with the layers each run credited. Nothing here asks the reader to trust the store: every layer is an independently runnable program over the quoted sources — rebuild the module and re-run the checkers to reproduce the verdict. Receipts attesting superseded builds credit no layer and are omitted from this rendering (the count of omissions, if any, is noted below).

| receipt          | minted               | layers                             | status  |
|------------------|----------------------|------------------------------------|---------|
| 6ff1345414960d8f | 2026-07-21T05:38:55Z | build+replay+hardened+decorrelated | current |

13 further receipt(s) in the store attest superseded builds of this module and are omitted from this rendering.

### gate-layer coverage of the bound build:

| hardened (safe_verify (hardened screen))                  | current |
| decorrelated (lean4export + nanoda (decorrelated kernel)) | current |

**comparator: none** no fixture in the three-implementation comparator harness (compiled / kernel-interpreted / reference-interpreted) exercises this rule.

## HOL4 statement

### NO HOL STATEMENT YET

The HOL4 development checks the base calculus's wire format (theory bern\_catalogue). The transport matrix's cells conclude judgments of the extension theory, whose rule sorts are out of scope of the current baked theory; the mechanized cells live in the auxiliary Lean package. Nothing exists yet for a HOL statement to be about; the box becomes writable when a revision carries the distance-judgment rows and its checker chain is ported.

## HOL verifier receipts

### NONE

no HOL verification receipt exists for this rule.

## Proof

Genre: core rule (tier 1). Scope, stated loudly: the finite-kernel tier — finite state spaces, distribution evolution, total-variation entries of the registry. The Lipschitz-pushforward cells for Wasserstein entries, the description-subject cells, and the per-cell composition-coherence squares are named successors, not claimed. Every hypothesis is used and remarked on.

**Setting and claim.** A *fine* chain (states  $\alpha$ , kernel  $K$ , initial law  $\mu_0$ ), a *coarse* chain (states  $\beta$ , kernel  $Q$ ), and a readout map  $\pi : \alpha \rightarrow \beta$ . Write  $\pi_{\#}$  for pushforward,  $\text{law}_K(n)$  for the time- $n$  law, and  $\text{TV}(p, q) = \frac{1}{2} \sum_l |p(l) - q(l)|$ . The witness comes in two grades: *exact intertwining* — every kernel row pushes exactly,  $\pi_{\#}K(s, \cdot) = Q(\pi(s), \cdot)$  — and  $\varepsilon$ -intertwining —  $\text{TV}(\pi_{\#}K(s, \cdot), Q(\pi(s), \cdot)) \leq \varepsilon$  for every  $s$ . The transport matrix's built cells, which are the claims proved below: (**strict**  $\times$  **exact**) laws transport unchanged at every horizon, so any judgment about the coarse law pulls back with zero degradation (`strict_cell_exact`); (**distance**  $\times$  **strict witness**) a total-variation distance judgment moves along any readout map unchanged (`sound_QDistSelfTransport`); (**strict**  $\times$   $\varepsilon$ -**witness** — **the degrading cell**) what transports is a *distance* judgment:  $\text{TV}(\pi_{\#}\text{law}_K(n), \text{law}_Q(n)) \leq n\varepsilon$  at declared horizon  $n$  (`sound_QDistTransport_eps`); and witnesses compose with  $\varepsilon_1 + \varepsilon_2$  (`epsPushKernel_comp`).

**Lemma R93.1** (data processing: pushforward is TV-nonexpansive). *For any map  $\pi$  and any  $p, q$ :  $\text{TV}(\pi_{\#}p, \pi_{\#}q) \leq \text{TV}(p, q)$ .*

*Proof.* Per label  $b$ ,  $|\sum_{\pi(s)=b} (p-q)(s)| \leq \sum_{\pi(s)=b} |p-q|(s)$ ; summing over  $b$  regroups the right side into  $\sum_s |p-q|(s)$ . Merging states can only cancel differences, never create them [160, Ch. 4]. This lemma is the (distance  $\times$  strict-witness) cell: a certified  $\text{TV} \leq \varepsilon$  on the fine side transports to the coarse side unchanged — the registry reading of total variation as a Lipschitz-1 entry under pushforward.  $\square$

**Lemma R93.2** (the coarse operator cannot amplify). *If  $Q$  is row-stochastic with nonnegative entries, then  $\text{TV}(\text{step}_Q p, \text{step}_Q q) \leq \text{TV}(p, q)$ .*

*Proof.*  $|\text{step}_Q(p-q)(t)| \leq \sum_s |p-q|(s) Q(s, t)$  by the triangle inequality and  $Q \geq 0$ ; summing over  $t$  and swapping sums, the inner  $\sum_t Q(s, t) = 1$  leaves  $\sum_s |p-q|(s)$ . Both hypotheses on  $Q$  are consumed: nonnegativity to pull the absolute value through, unit row sums to collapse the mass.  $\square$

**Lemma R93.3** (one-step defect). *Let  $\mu$  be a probability law and let the  $\varepsilon$ -intertwining rows hold. Then  $\text{TV}(\pi_{\#}(\text{step}_K \mu), \text{step}_Q(\pi_{\#} \mu)) \leq \varepsilon$ .*

*Proof.* Both sides are  $\mu$ -mixtures of per-state rows:  $\pi_{\#}(\text{step}_K \mu) = \sum_s \mu(s) \pi_{\#} K(s, \cdot)$  and  $\text{step}_Q(\pi_{\#} \mu) = \sum_s \mu(s) Q(\pi(s), \cdot)$  (the second by regrouping the coarse step over the fibres of  $\pi$ ). Total variation is jointly convex — a mixture of pairs is bounded by the mixture of pairwise distances — so the defect is at most  $\sum_s \mu(s) \cdot \varepsilon = \varepsilon$ , using that  $\mu$  is nonnegative with total mass 1.  $\square$

**Theorem R93.4** (the degrading cell: horizon-compounded transport). *With  $K, Q$  row-stochastic,  $\mu_0$  a probability law, and the  $\varepsilon$ -intertwining rows: for every  $n$ ,*

$$\text{TV}(\pi_{\#} \text{law}_K(n), \text{law}_Q(n)) \leq n\varepsilon,$$

where the coarse chain starts from  $\pi_{\#} \mu_0$ .

*Proof.* Induction on  $n$ ; the base is  $\text{TV}(x, x) = 0$ . Step, by the triangle inequality through the hybrid term  $\text{step}_Q(\pi_{\#} \text{law}_K(n))$ :

$$\begin{aligned} \text{TV}(\pi_{\#} \text{law}_K(n+1), \text{law}_Q(n+1)) &\leq \underbrace{\text{TV}(\pi_{\#} \text{step}_K \text{law}_K(n), \text{step}_Q \pi_{\#} \text{law}_K(n))}_{\leq \varepsilon \text{ (Lemma R93.3, at the time-}n \text{ law)}} + \underbrace{\text{TV}(\text{step}_Q \pi_{\#} \text{law}_K(n), \text{step}_Q \text{law}_Q(n))}_{\leq n\varepsilon \text{ (Lemma R93.2 + induction)}}. \end{aligned}$$

The compounding law is thus *proved*, not guessed: one fresh defect per step, prior error never amplified. A strict judgment does NOT transport along an  $\varepsilon$ -witness; what transports is a distance judgment with  $\varepsilon$  inherited and horizon-compounded — precisely this cell.  $\square$

**Proposition R93.5** (witness composition). *If  $\sigma_1 = (\pi_1, \varepsilon_1)$  intertwines  $K_1$  with  $K_2$  and  $\sigma_2 = (\pi_2, \varepsilon_2)$  intertwines  $K_2$  with  $K_3$ , then  $\pi_2 \circ \pi_1$  is an  $(\varepsilon_1 + \varepsilon_2)$ -witness from  $K_1$  to  $K_3$ .*

*Proof.* At any state  $s$ , triangle through the mid-tier row  $\pi_{2\#} K_2(\pi_1(s), \cdot)$ : the first leg is  $\text{TV}(\pi_{2\#} \pi_{1\#} K_1(s, \cdot), \pi_{2\#} K_2(\pi_1(s), \cdot)) \leq \varepsilon_1$  by Lemma R93.1 applied to  $\sigma_1$ 's row defect; the second leg is  $\sigma_2$ 's row at  $\pi_1(s)$ . Plain addition records the honest upper bound at this tier —  $\varepsilon_1 + \varepsilon_2$  is what the triangle gives, with no minimality claim: data processing can gain slack (a constant second projection has composite defect 0 whatever  $\varepsilon_1$  was).  $\square$

**Proposition R93.6** (the strict column is the  $\varepsilon = 0$  instantiation). *Exact intertwining holds iff the rows are 0-intertwining; under it,  $\pi_{\#} \text{law}_K(n) = \text{law}_Q(n)$  for every  $n$ , and every judgment about the coarse law pulls back with zero degradation.*

*Proof.*  $(\Rightarrow)$  equal rows have distance 0.  $(\Leftarrow)$   $\text{TV}(p, q) \leq 0$  forces  $p = q$  entrywise (a sum of absolute values is zero only if each vanishes). The exact law transport is then the marginal-process induction (the same pushed-row-identity induction as the QCOUPLEDRIFT section's marginal-process lemma, there instantiated at product projections, here at an arbitrary readout map), or equivalently Theorem R93.4 at  $\varepsilon = 0$ .  $\square$

**Remark R93.7** (why each hypothesis is needed). *Row-stochasticity of  $Q$*  (Lemma R93.2): a non-stochastic coarse operator amplifies — with  $Q = 2 \text{Id}$  each step doubles any existing difference and the telescoping collapses; with signed entries the absolute value cannot be pulled through.  *$\mu$  a probability law* (Lemma R93.3): mixture convexity needs nonnegative weights of total mass one — weights summing to 2 double the defect. *The declared horizon*: the linear rate is sharp to first order without further rows — on the two-state fine chain that leaks mass  $\varepsilon$  toward an absorbing label each step, against a static coarse chain, the distance at horizon  $n$  is  $1 - (1 - \varepsilon)^n = n\varepsilon - O(n^2 \varepsilon^2)$ , so no  $o(n\varepsilon)$  bound holds, and over unbounded horizons the error climbs to order one — the  $\varepsilon$ -cell therefore *refuses* unbounded horizons rather than extrapolating; a contraction row is the named mechanism that would buy a uniform-in- $n$  bound, and it is a different certificate. *Per-row quantification* of the intertwining: a defect bound only at states charged by  $\mu_0$  fails at later times, since the law spreads — the rows are quantified over all states precisely so Lemma R93.3 applies at every time- $n$  law.

**Remark R93.8** (relation to the literature). The degrading cell is the kernel-tier, exact-arithmetic face of approximate simulation with quantitative degradation [93]: there, an  $\varepsilon$ -approximate (bi)simulation transports properties up to a metric slack; here the slack is total variation, the systems are finite kernels, and the horizon-compounding law is proved from mixture convexity plus data processing. Behavioural pseudometrics for probabilistic systems [61] are the semantic tradition the distance-judgment registry discretizes; the coupling toolkit is classical [160, 166]. The matrix framing — judgment class  $\times$  witness class, one lemma and one refusal condition per cell — is the rule's own contribution: it makes “what survives transport along a defective witness” a typed question with a proved answer per cell, instead of a convention.

## 15.12 Stored-Chain Certificate Species

### Rule 94. DTMCABSORBBRACKET (core rule)

#### The rule (Steele metanotation)

as realized in the mechanized development; source row: QTSL-rules.toml — *DtmcAbsorbBracket*. The metanotation statement is typeset by hand for notational quality; this rule cites no Lean statements yet (the absence is stated loudly below). The rule *roster* is machine-checked (every mechanized rule tag round-trips to exactly one catalogue row); the statement *text* is editorial.

$$\frac{q : \text{DAbsQuery} \quad \text{qtsl\_dabs\_wf}(q) \quad \text{stored rows of } q.\text{chain} \text{ (dprob, dinit, dclass, dreject)}}{\text{qtsl\_dabs\_absorb\_bracket}(q, c, lo, hi)}$$

DTMCABSORBBRACKET is a certificate species rather than a proof-node rule: a checker-recomputed claim over the stored rows of a finite chain, introducing zero new judgment sorts and zero new specification formers. It certifies guaranteed two-sided brackets on the eventual-absorption measure of one class of a finite stored-row chain — and, through its normalized sibling DTMCPOSTERIORBRACKET, on normalized conditional measures (posteriors of discrete probabilistic programs, where the compilation of a program to a chain is an untrusted translation outside the trust path). The species is stated at full generality: any finite chain, any class labeling, any horizon.

The evaluation semantics, once:  $m_0$  is the chain's stored initial measure;  $m_{t+1} = m_t K$ , where  $K$  is the stored transition-row matrix COMPLETED by a self-loop at every state with no stored outgoing row (*rowless-is-absorbing*). For a query with horizon  $T$ , class labeling, and rejection labeling:  $N_c$  is the class- $c$  mass of  $m_T$ ;  $S = \sum_c N_c$ ;  $R = 1 - S$  (rejected mass of  $m_T$ ); and  $R_c$  is the *reachability-sharpened* per-class residual — the part of  $R$  sitting at states from which some class- $c$  state is reachable through strictly positive stored rows (a backward walk seeded at the class, run under the same work budget; budget exhaustion during the walk refuses the whole claim, never verdicts). The claim holds iff  $lo \leq N_c$  and  $N_c + R_c \leq hi$ . Mass that can never arrive in the class is never charged to it: a class unreachable from every alive state has  $R_c = 0$  and a width-zero bracket at any  $T \geq 1$ , with no termination assumption; and  $R_c \leq R$  always, so any claim admissible under the uniform-residual reading stays admissible.

The completion convention is the species' load-bearing design move: a truncated row set can only WIDEN brackets (unclassified mass accrues to the residual, never to any class), so row-set completeness is a tightness concern rather than a soundness obligation — there is no closure side condition, deliberately, and under-expansion is unrepresentable as an attack. Derived quantities ( $N_c$ ,  $S$ ,  $R$ ,  $R_c$ , ratio denominators) are never stored: the evaluator recomputes them from the chain rows, so forging an intermediate is unrepresentable; claims may be looser than canonical, never tighter.

Soundness has two sides. Below, absorption is monotone: classed states are demanded stored-absorbing (the well-formedness side condition), so class mass never decreases past the horizon. Above, the class's co-reachable set  $B_C$  (states with a strictly-positive-support path into the class;  $C \subseteq B_C$ ) has a forward-closed complement — no positive-support row leads from outside  $B_C$  into it — so the mass of  $B_C$  is nonincreasing and later class gain is bounded by  $\text{mass}_T(B_C \setminus C) = R_c$ . The uniform-residual bound ( $R_c$  relaxed to  $1 - \text{mass}_T(\text{Abs})$ ) is the pre-sharpening corollary. The argument is mechanized in the accompanying Lean development (SuFunctor/Adequacy/DtmcAbsorb.lean; sorry-free, standard axiom closure, axiom-audited on every build): the sharpened upper side  $\text{dtmcAbsorb\_mass\_le\_reach}$  is notably HYPOTHESIS-FREE on the class — it holds for any class of any finite stochastic chain, the well-formedness demands protecting only the monotone lower side; beside it sit  $\text{dtmcAbsorbBracket\_reach\_sound}$  (the bracket, both sides),  $\text{dtmcAbsorb\_reach\_residual\_le}$  (the never-loosens warrant  $R_c \leq 1 - \text{mass}_T(\text{Abs})$ , itself needing only that absorbing states absorb),  $\text{dtmcAbsorb\_eventual\_bracket\_reach}$  (the claim shape), the forward-closed generalization ( $\text{FinDTMC.ForwardClosed}$ ,  $\text{dtmc\_mass\_mono\_of\_forwardClosed}$ ) from which the incumbent monotonicity lemmas re-derive in one line, and a kernel-checked strict-improvement witness ( $\text{idBool\_strict\_improvement}$ : an unreachable class where the uniform-residual bracket has width one and the sharpened bracket width zero — a standing regression tooth, re-checked every build). The mechanized statements are deliberately universally quantified ( $\forall t' \geq T$ ) rather than supremum-shaped: over  $\mathbb{Q}$  the supremum of a monotone bounded mass sequence need not exist as a rational, and the universal form is the citable content — any eventual-absorption reading (sup or limit, in any completion of  $\mathbb{Q}$ ) inherits the claimed bracket.

One clause of the species is graded prose by design: the *truncation-transfer* reading — stored rows agreeing with an external program's chain on rowed states implies the bracket transfers to the program — is a coupling argument about a translation that lives OUTSIDE the trust path, and its assurance instrument is a battery (vendored source, Monte-Carlo differential, closed-form containment), not a kernel theorem. The certificate itself never claims more than the stored rows warrant.

**notes** The schema is baked in the certificate theory as a species sibling extending the chain grain, purely additive — the query sort with anchor-mediated chain binding (the query's chain IS its anchor's chain, labels bound by chase rows), the horizon field, the class and rejection labelings, and the three side-condition Props with their report, refusal, and chase rows, all quoted below from the theory source. The doubly-classed state is unrepresentable at the attribute grain (the class labeling is a keyed function row). The mechanized soundness lemmas are named in the commentary; no Lean statement is bound into this book yet — the binding column is honest open debt, and joins when the statement-binding machinery registers the development's package.

## Theory rows (geolog)

The rule's certificate content as it is declared in the geolog theory the checker loads — payload schema, side-condition demands, and axiom rows, quoted from the theory source at every build of this catalogue (a stale quotation cannot exist). Axiom modes: chase = the engine derives; report = a violation is a loud judgment; refuse = a violation gates admission. Side-condition relations are discharged by bounded evaluation at the engine's ground seam, never by derivation.

The chain grain this species reads: states, stored transition rows, stored initial rows, and the row-mass admission demand. The species adds no rows here; it consumes them.

theory Dtmc . **DState**

quoted from the theory source at render

```
| DState : Set;    // one state of one chain
```

theory Dtmc . **dprob**

quoted from the theory source at render

```
| dprob : {src: DState, dst: DState} -> Q;
```

## Lean statement

**not yet mechanized** this rule cites no Lean statements: nothing on this page is hash-bound for it, and its dashboard row shows the same absence across the statement, receipt, and correspondence columns.

## HOL4 statement

### NO HOL STATEMENT YET

No HOL development of the extension theory exists; this species' content is an exact-rational evaluator recompute over baked rows, and its soundness theorems live in the Lean development named in the commentary.

## HOL verifier receipts

### NONE

no HOL verification receipt exists for this rule.

## Proof

Genre: certificate species (tier 1 semantic soundness; checker recomputation, no proof node). The proof below is the mechanized argument restated at textbook detail; the named Lean declarations carry it, sorry-free at standard axiom closure.

**Setting.** A finite stored-row chain: state set  $X$ , stored transition rows  $K_0 \subseteq X \times X \rightarrow \mathbb{Q}_{\geq 0}$  satisfying the row-mass admission demand (each rowed source's stored masses total exactly one), stored initial measure  $m_0$ , horizon  $T \in \mathbb{N}$ , class labeling and rejection labeling over  $X$ . Let  $K$  be  $K_0$  completed by a unit self-loop at every state with no stored outgoing row (*rowless-is-absorbing*);  $K$  is then a stochastic matrix on  $X$ , and  $m_{t+1} := m_t K$  defines the exact-rational evolution. Write  $C$  for the set of class- $c$  states, Abs for the labeled (classed or rejected) states — each demanded stored-absorbing by the well-formedness side condition: rowless, or exactly the unit self-loop — and  $N_c := \text{mass}_T(C)$ ,  $S := \sum_{c'} N_{c'}$ ,  $R := 1 - S$  — (rejected mass of  $m_T$ ).

**Lemma 1 (monotone absorption — the lower side).** For  $t' \geq T$ :  $\text{mass}_{t'}(C) \geq \text{mass}_T(C)$ . *Proof.* Each state of  $C$  is stored-absorbing, so under  $K$  its mass never leaves; class mass is nondecreasing step by step. (Removing the well-formedness hypothesis admits the counterexample the mutant battery pins: a classed state with a stored mass-leaking outgoing row loses class mass at the very next step.)  $\square$

**Lemma 2 (forward-closed complement — the upper side).** Let  $B_C$  be the co-reachable set of  $C$ : states admitting a path into  $C$  through strictly positive stored rows ( $C \subseteq B_C$ ). Then  $X \setminus B_C$  is forward-closed — no positive-support row of  $K$  leads from outside  $B_C$  into  $B_C$  (such a row would itself witness co-reachability of its source) — hence  $\text{mass}_{t'}(B_C)$  is nonincreasing in  $t'$ . *Proof.* For a forward-closed set  $F$ ,  $1_F K^\top \geq 1_F$  pointwise on  $F$ 's complement contributes nothing, and mass on  $F$  can only stay or grow; apply to  $F = X \setminus B_C$  and complement. This is the mechanized generalization (FinDTMC.ForwardClosed, dtmc\_mass\_mono\_of\_forwardClosed), from which Lemma 1 re-derives in one line: a stored-absorbing set is forward-closed around each of its points.  $\square$

**Theorem (the bracket).** Define  $R_c := \text{mass}_T(B_C \setminus C)$  (the reachability-sharpened per-class residual, recomputed by a backward walk over strictly positive stored rows, seeded at  $C$ , under the same work budget — exhaustion refuses the whole claim). For every  $t' \geq T$ :

$$\text{mass}_{t'}(C) \in [\text{mass}_T(C), \text{mass}_T(C) + R_c].$$

*Proof.* Lower: Lemma 1. Upper: class mass at  $t'$  sits inside  $B_C$  (mass outside  $B_C$  can never arrive in  $C$ , by Lemma 2 applied along the trajectory), and  $C$ 's gain since  $T$  is at most  $B_C$ 's non- $C$  mass at  $T$ , which is  $R_c$ , since  $B_C$ 's total is nonincreasing while its  $C$ -part is nondecreasing.  $\square$

The mechanized upper side (`dtmcAbsorb_mass_le_reach`) is HYPOTHESIS-FREE on the class: it holds for any class of any finite stochastic chain — the well-formedness demands protect only Lemma 1. The never-loosens warrant (`dtmcAbsorb_reach_residual_le`) gives  $R_c \leq 1 - \text{mass}_T(\text{Abs})$ , needing only that labeled states absorb, so every claim admissible under the uniform residual remains admissible under the sharpened one; and the strict-improvement tooth (`idBool_strict_improvement`) exhibits an unreachable class where the uniform bracket has width one and the sharpened bracket width zero — a standing kernel-checked regression witness. A class unreachable from every alive state has  $R_c = 0$ : a width-zero bracket at any  $T \geq 1$ , with no termination assumption anywhere.

**Corollary (eventual readings).** The statements are universally quantified over  $t' \geq T$  deliberately: over  $\mathbb{Q}$  the supremum of the monotone bounded sequence  $\text{mass}_{t'}(C)$  need not exist as a rational. Any eventual-absorption reading — supremum or limit, in any completion of  $\mathbb{Q}$  — inherits the claimed bracket from the universal form (`dtmcAbsorb_eventual_bracket_reach`).

**Why each hypothesis.** Row-mass admission: without it, doubled stored masses inflate  $N_c$  (a battery locus). The well-formedness demand: Lemma 1's counterexample above. The budget refusal on the backward walk: a partial walk could under-build  $B_C$ , dropping states whose mass belongs in  $R_c$  — so exhaustion refuses rather than verdicts. Interval order  $lo \leq hi$  is a report row; inversion refuses. And the completion convention (rowless-is-absorbing) makes truncation *widen* brackets: omitted rows leave their states absorbing and their mass in the residual, never in a class — there is no closure side condition to attack, and claims may be looser than canonical, never tighter.

*Remark R94.1 (status).* The schema is baked (species rows quoted in this section); the argument above is mechanized sorry-free at standard axiom closure, axiom-audited on every build, in the module named in the commentary. No Lean statement is bound into this book yet: the binding column is honest open debt until the statement-binding machinery registers the development's package.

## Rule 95. DTMCPOSTERIORBRACKET (core rule)

### The rule (Steele metanotation)

as realized in the mechanized development; source row: QTSL-rules.toml — *DtmcPosteriorBracket*. The metanotation statement is typeset by hand for notational quality; this rule cites no Lean statements yet (the absence is stated loudly below). The rule *roster* is machine-checked (every mechanized rule tag round-trips to exactly one catalogue row); the statement *text* is editorial.

$$\frac{q : \text{DAbsQuery} \quad \text{qtsl\_dabs\_wf}(q) \quad \text{stored rows of } q.\text{chain}(\text{dprob}, \text{dinit}, \text{dclass}, \text{dreject}) \quad S > 0 \text{ (recomputed; refusal otherwise)}}{\text{qtsl\_dabs\_posterior\_bracket}(q, c, lo, hi)}$$

DTMCPOSTERIORBRACKET is the normalized face of DTMCABSORB: a bracket on the *posterior* eventual-absorption measure of one class, with normalizer the total classed mass. Hard conditioning is a CLASS, not a score: rejected mass (failed conditioning) and unlabeled or nonterminating mass are excluded from the normalizer by the same labeling mechanism, so every stored row remains a probability row and the chain grain's row-mass admission demand is untouched. This is what lets posteriors of discrete probabilistic programs ride the species without any weighted-row machinery.

The claim holds iff  $lo \leq N_c/(S+R)$  and  $(N_c+R)/(S+R) \leq hi$ , with  $N_c, S, R$  recomputed by the same  $T$ -step exact-rational evaluation as the sibling; it REFUSES at  $S = 0$  (no positive-evidence witness). The mathematical content beyond the sibling's conservation bracket is the correlated-ratio lemma — pure algebra, no chain in sight: from  $N_c \leq M_c$  classwise,  $\sum_c (M_c - N_c) \leq R$ , and  $S > 0$ , the true posterior lies in  $[N_c/(S+R), (N_c+R)/(S+R)]$ . The correlation is the point: numerator and denominator draw their errors from ONE budget, so both endpoints use the single normalizer  $S+R$  rather than the looser interval quotient — never worse, often sharper (measured  $3.0\times$  tighter than the interval-quotient baseline at matched truncation on the species' first worked example). Mechanized as *dtmcPosteriorBracket\_sound*, over any finite class alphabet, in the same module and with the same receipts as the sibling.

An honesty note carried from the design: the bracket width is exactly  $R/(S+R)$ , class-uniform — the tightness of the whole judgment is one number, which is what keeps comparison-table claim shapes honest. The posterior face deliberately keeps the UNIFORM residual  $R$  even though the unnormalized sibling mints with the reachability-sharpened  $R_c$ : the single-normalizer argument requires one shared budget across all classes, and the class-uniform width claim stays honest only under it. An asymmetric refinement (uniform lower endpoint, class-specific upper endpoint  $(N_c+R_c)/(S+R_c)$ ) is sound and is deliberately NOT minted — it boards a future revision of the theory if and when a use case demands it.

**notes** The schema is baked in the certificate theory alongside the sibling: same query sort, labelings, and well-formedness demand; its own claim relation with its own interval-order report; the  $S > 0$  refusal is evaluator-side (a recompute refusal, not a stored row). Quoted below from the theory source. No Lean statement is bound into this book yet — the binding column is honest open debt, as the sibling.

### Theory rows (geolog)

The rule's certificate content as it is declared in the geolog theory the checker loads — payload schema, side-condition demands, and axiom rows, quoted from the theory source at every build of this catalogue (a stale quotation cannot exist). Axiom modes: *chase* = the engine derives; *report* = a violation is a loud judgment; *refuse* = a violation gates admission. Side-condition relations are discharged by bounded evaluation at the engine's ground seam, never by derivation.

The baked rows beyond the sibling's: the posterior claim relation and its interval-order report. The query sort, labelings, and well-formedness demand are the sibling's own rows, quoted in its section.

  {q: q, class: c, lo: l, hi: h} qtsl_dabs_posterior_bracket
|- {l: l, r: h} q_le;
```

### Lean statement

**not yet mechanized** this rule cites no Lean statements: nothing on this page is hash-bound for it, and its dashboard row shows the same absence across the statement, receipt, and correspondence columns.

## HOL4 statement

### NO HOL STATEMENT YET

No HOL development of the extension theory exists; this species' content is an exact-rational evaluator recompute over baked rows plus one algebraic lemma, mechanized in the Lean development named in the commentary.

## HOL verifier receipts

### NONE

no HOL verification receipt exists for this rule.

## Proof

Genre: certificate species (tier 1 semantic soundness; checker recomputation, no proof node). The content beyond the unnormalized sibling is one algebraic lemma, proved here in full; the mechanized form is `dtmcPosteriorBracket_sound`, over any finite class alphabet.

**Setting.** As in `DTMCABSORBBRACKET`: from the  $T$ -step evaluation, per-class truncation masses  $N_c \geq 0$ , their total  $S = \sum_c N_c$ , and the residual  $R \geq 0$ . Write  $M_c$  for the true eventual class- $c$  mass (any completion-valued reading). The sibling's conservation bracket gives, classwise,  $N_c \leq M_c$  and  $\sum_c (M_c - N_c) \leq R$ .

**Lemma (correlated ratio).** If additionally  $S > 0$ , then for every class  $c$ :

$$\frac{M_c}{\sum_{c'} M_{c'}} \in \left[ \frac{N_c}{S+R}, \frac{N_c+R}{S+R} \right].$$

*Proof.* Let  $\delta_{c'} := M_{c'} - N_{c'} \geq 0$  and  $\Delta := \sum_{c'} \delta_{c'} \leq R$ . The denominator is  $\sum_{c'} M_{c'} = S + \Delta \in [S, S+R]$ , and  $S > 0$  makes every quotient well-defined. Upper endpoint:

$$\frac{M_c}{S+\Delta} = \frac{N_c + \delta_c}{S+\Delta} \leq \frac{N_c + \Delta}{S+\Delta} \leq \frac{N_c + R}{S+R},$$

the first step since  $\delta_c \leq \Delta$ , the second since  $x \mapsto (N_c + x)/(S + x)$  is nondecreasing for  $x \geq 0$  (as  $N_c \leq S$ ) and  $\Delta \leq R$ . Lower endpoint:

$$\frac{M_c}{S+\Delta} \geq \frac{N_c}{S+\Delta} \geq \frac{N_c}{S+R}.$$

□

The correlation is the content: numerator and denominator draw their errors from the ONE budget  $\Delta \leq R$ , so both endpoints use the single normalizer  $S + R$ . The uncorrelated alternative — bracket numerator and denominator separately and take the interval quotient  $[N_c/(S+R), (N_c+R)/S]$  — is never better and usually worse; at matched truncation on the species' first worked example the correlated form measured 3.0× tighter.

**Why each hypothesis.**  $S > 0$ : at  $S = 0$  the posterior is 0/0-shaped and the species REFUSES (no positive-evidence witness) — a refusal, never a verdict. Nonnegativity of the  $\delta_{c'}$  is exactly the sibling's monotone lower side; the one-budget bound  $\Delta \leq R$  is its conservation upper side, summed. Hard conditioning enters as a CLASS (rejected mass leaves the normalizer by labeling), so every stored row remains a probability row and no weighted-row machinery is consumed.

**Width honesty.** Both endpoints differ by exactly  $R/(S+R)$ , class-uniformly: the tightness of the whole judgment is one number. The posterior face deliberately keeps the uniform  $R$  (the one-budget argument above requires a single normalizer shared by all classes); the asymmetric per-class refinement with upper endpoint  $(N_c + R_c)/(S + R_c)$  is sound and deliberately not part of this revision — it boards a future one if a use case demands it.

*Remark R95.1 (status).* The schema is baked (claim relation and interval-order report quoted in this section; query sort and labelings in the sibling's). The lemma above is mechanized sorry-free at standard axiom closure over any finite class alphabet. No Lean statement is bound into this book yet: the binding column is honest open debt, as the sibling's.

## Rule 96. QGENFORMCONTRACTION (core rule)

### The rule (Steele metanotation)

as realized in the mechanized development; source row: `QTSL-rules.toml` — `QGenFormContraction`. The metanotation statement is typeset by hand for notational quality; this rule cites no Lean statements yet (the absence is stated loudly below). The rule *roster* is machine-checked (every mechanized rule tag round-trips to exactly one catalogue row); the statement *text* is editorial.

$$\begin{array}{c}
 w : \text{DGenContraction} \\
 \text{stored rows: } \text{dweight } (A = \text{supp } V, \text{ nonempty}), \text{ dprob, dinit} \quad \sum_{y \in A} K(x, y) V(y) \leq c V(x) \quad \forall x \in A \\
 K(x, y) = 0 \text{ for stored rows } x \notin A, y \in A \quad \min_A V > 0 \quad \text{qtsl\_dtmc\_genform\_contraction}(w) \\
 \hline
 \text{each claimed row of } w : \text{qtsl\_dgc\_partial\_lo, qtsl\_dgc\_ev\_bracket, qtsl\_dgc\_survival\_tail, qtsl\_dgc\_z\_one}
 \end{array}$$

QGENFORMCONTRACTION strengthens the chain-content generator-form seam from the incumbent's boolean claim — transfer of the certificate is nonpositive-drift — to a score-carrying, regional, *quantitative* contraction whose conclusions include the incumbent's and add geometric tails, first-moment tails, and a termination-mass-one claim. It is a certificate species, not a proof-node rule: checker recomputation over stored rows, zero new judgment sorts, zero new formers. The mechanized carrier is an arbitrary nonnegative weight matrix (the score factorization  $s(x)K(x, y)$  is presentation, not mathematics), so stochastic, sub-probability, and soft-score row sets ride ONE induction.

This is the fold-don't-sibling reading of the change discipline enacted: the would-be separate weighted-tail species folds into the incumbent seam, and the incumbent survives as the degenerate face (score  $\equiv 1$ ,  $c = 1$ , region = all states) — its rows, wire shape, and consuming lemmas untouched. Subsumption is mechanized twice over, as the strengthening discipline demands: the instance chain (the weighted core at  $s \equiv 1$  on a stochastic kernel re-derives the previously proven stochastic core's exact statement: `massAt_expect_le_of_contraction_of_weighted`) and the composed theorem (`qGenFormContraction_subsumes_genform`: from the incumbent's recomputed nonpositive generator form, the strengthened engine derives the incumbent consumption's exact path-law conclusion, never by citing the incumbent's own proof) — so every certificate admitted under the incumbent discharges under the strengthening with an unchanged conclusion.

The evaluator recomputes, per stored row: the region-restricted weighted contraction  $\sum_{y \in A} K(x, y)V(y) \leq c V(x)$  on the region  $A$ ; no re-entry ( $K(x, y) = 0$  for stored rows from outside  $A$  into  $A$  — equivalently, the complement is closed); and the strictly positive region minimum  $\mu = \min_A V > 0$ . Conclusions, each bound exactly where its claim row is spent: weighted alive-mass decay  $\langle m_t | A, V \rangle \leq c^t \langle m_0 | A, V \rangle$ ; for  $c < 1$ , window exit-weight truncation and the time-weighted first-moment tail (the expected-value rows' engine); the exact partial survival sum (the lower claim); and — through the DERIVED conversion  $1/\mu$  rescaling the mechanized unit-floor lemma by scale-invariance — the bare alive-mass tail  $\text{mass}_t(A) \leq c^t \langle m_0 | A, V \rangle / \mu$ , the stored-row form of a hitting-time tail  $\Pr[\text{hitting time} > t] \leq M c^t$  (a self-stabilization time's region is the not-yet-stabilized configurations, whose complement's closedness is exactly the no-re-entry recompute).

The enacted schema's deviations from the drafted proposal are each load-bearing. There is NO stored exit or conversion constant: the constant is derived ( $1/\min_A V$ , with the minimum demanded strictly positive) because a stored constant would be a forgeable derived quantity — the species' own never-store-what-you-can-recompute discipline. The region IS the weight relation's support (a stored weight row is the stored membership; no separate region relation to fall out of sync). Four NAMED claim relations replace a flavor datum — partial lower bound, expected-exit-time bracket, survival tail, and termination-mass-one — making the wire self-documenting and letting each side condition bind exactly where its conclusion is spent (the  $c < 1$  demand binds exactly at tail-claiming rows; at  $c = 1$  the incumbent decay-only conclusion remains). A PRESENT score field REFUSES at this revision (deferred-safe-fail): the mechanized core is already score-carrying, and the evaluator face for present scores boards its own future revision rather than shipping unexercised. Higher moments ( $k \geq 2$ ) are deliberately absent — the same per-term reduction with  $\sum t^k c^t$  closed forms, filed to the first leg that needs them.

The soundness engine is the weighted-transfer induction (one-step transfer, induction on  $t$ , geometric series — no stochastic analysis anywhere), mechanized sorry-free at standard axiom closure and axiom-audited on every build (`SuFunctor/Adequacy/DtmcContraction.lean`): `wmassAt` with the instance tie `massAt_eq_wmassAt`; the core `wmassAt_expect_le_of_contraction` (certificate nonnegativity DROPPED — strictly stronger than the drafted specification); the score face; the regional packaging via the region-supported observable; exit domination; the exact arithmetico-geometric identity and series tails; and the two tail assemblies, in universally-quantified partial-sum form (over  $\mathbb{Q}$  the limit need not exist; any completion-valued reading inherits the bound). The alive-mass face lives on its own module (`SuFunctor/Adequacy/DtmcAliveTail.lean`): `massAt_expect_on_le_of_regionContraction` and `dtmcAliveTail_of_regionContraction`, whose two added hypotheses — the floor and the closed complement — are each witnessed load-bearing by kernel-checked countermodels COMMITTED beside the lemmas (`aliveTail_needs_floor`, `aliveTail_needs_no_reentry`), re-checked on every build. The species' mutant battery was run as committed throwaway edits, each red at its predicted load-bearing proof step.

Two further faces are deliberately NOT part of this revision. The TEMPLATE face (geometric certificate families  $V(n) = M\gamma^n$  over offset families, collapsing region instances to single rational inequalities) and the PATTERN face (finitely-presented infinite chains and product-profile templates) are deferred to their own design work: the pattern face is underdetermined at this grain (no canonical state-coordinate binding; a pattern's generated kernel and the stored completion's rowless-is-absorbing

reading are two different kernels and must not share one chain reading; and the finite-state induction does not by itself warrant infinite-sum exchange — a carrier theorem is owed), and no admitted certificate demands the one-dimensional template at the stored-weights grain, where the finite face stores every weight. Their collapse warrants are already mechanized and banked for that future work (`genFormTemplate_collapse` for one-dimensional offset families; `aliveStep_factor`, `transferRatio_of_ge`, `productProfile_collapse` and its window form, `SuFunctor/Adequacy/DtmcProductProfile.lean`, proven at full profile generality), together with a kernel-checked necessity witness (`rampProfile_needs_window_reach`) showing the class-check family alone cannot cover ramp-resident exterior states — so the face's eventual schema must carry a profile-length demand beside window coverage. What remains for that face is the infinite-carrier bridge, the kernel-object tie, and the stored/template composition glue; until then, template- and pattern-shaped claims live outside the certified lane, labeled as such.

**notes** The FINITE FACE is baked in the certificate theory as a species sibling extending the chain grain, purely additive: the witness entity (anchor-mediated chain binding, absolute horizon, the deterministic-prologue offset datum, the contraction constant, the optional score reference whose presence refuses at this revision), the keyed weight relation whose support is the region (nonempty demanded), the engine-decided demand minted per witness by a report row, and the four named claim relations with their range and interval-order reports — all quoted below from the theory source. The incumbent generator-form rows are untouched (additive delta only), and the sibling species' deliberately-absent notes carry their pointer flips from the same revision. The mechanized soundness lemmas are named in the commentary; no Lean statement is bound into this book yet — the binding column is honest open debt.

## Theory rows (geolog)

The rule's certificate content as it is declared in the geolog theory the checker loads — payload schema, side-condition demands, and axiom rows, quoted from the theory source at every build of this catalogue (a stale quotation cannot exist). Axiom modes: `chase` = the engine derives; `report` = a violation is a loud judgment; `refuse` = a violation gates admission. Side-condition relations are discharged by bounded evaluation at the engine's ground seam, never by derivation.

The incumbent seam this species strengthens — and survives as the degenerate face of: the chain-content generator-form demand.

theory Dtmc . **qtsl\_dtmc\_genform**

quoted from the theory source at render

```
qtsl_dtmc_genform : {sys: System, cert: HypernetRef,
                    gen: HypernetRef} -> Prop;
```

The baked rows of the finite face: the witness entity, the weight relation with its same-chain chase row, the engine-decided demand, and the four named claim relations with their wf reports (constant range, interval order on expected-value brackets, tail-coefficient ranges, and the strict-contraction demand exactly where an expected-value bracket is claimed).

theory DtmcContraction . **DGenContraction**

quoted from the theory source at render

c = w DGenContraction/c  
|- {l: c, r: 1} q\_lt;

## Lean statement

**not yet mechanized** this rule cites no Lean statements: nothing on this page is hash-bound for it, and its dashboard row shows the same absence across the statement, receipt, and correspondence columns.

## HOL4 statement

### NO HOL STATEMENT YET

No HOL development of the extension theory exists; this species' content is an exact-rational evaluator recompute over baked rows, and its soundness theorems live in the Lean development named in the commentary.

## HOL verifier receipts

### NONE

no HOL verification receipt exists for this rule.

## Proof

Genre: certificate species (tier 1 semantic soundness; checker recomputation strengthening an existing seam). The proof is the weighted-transfer induction plus exact series arithmetic — no stochastic analysis anywhere; the mechanized lemma roster is named inline.

**Setting.** A finite stored-row chain with completed kernel  $K$  (rowless-is-absorbing, as in the sibling species); a stored weight function  $V$  on the region  $A := \text{supp } V$  (the region IS the support of the stored weight rows — nonempty demanded); a contraction constant  $c \in [0, 1]$ ; and the recomputed side conditions: regional contraction  $\sum_{y \in A} K(x, y) V(y) \leq c V(x)$  for every  $x \in A$ ; no re-entry,  $K(x, y) = 0$  for stored rows with  $x \notin A, y \in A$  (equivalently, the complement of  $A$  is closed); and strictly positive region minimum  $\mu := \min_A V > 0$ . The carrier of the mechanized core is an arbitrary nonnegative weight matrix — the score factorization  $s(x)K(x, y)$  is presentation, not mathematics — so stochastic, sub-probability, and soft-score row sets ride one induction; certificate nonnegativity is NOT assumed by the core (`wmassAt_expect_le_of_contraction`), which is strictly stronger than the drafted specification.

**Lemma 1 (one-step transfer).** With  $w_t := \langle m_t|_A, V \rangle$  the region-supported weighted mass:  $w_{t+1} \leq c w_t$ . *Proof.* Expand  $m_{t+1} = m_t K$ ; mass entering  $A$  from outside contributes nothing (no re-entry), and each  $x \in A$  contributes  $m_t(x) \sum_{y \in A} K(x, y) V(y) \leq c m_t(x) V(x)$  by the recomputed contraction, using nonnegativity of kernel entries and of the evolving mass (the two mutant loci at this step). Sum over  $x \in A$ .  $\square$

**Theorem (decay, tails, termination).** By induction,  $w_t \leq c^t w_0$  (weighted alive-mass decay — at  $c = 1$  this is exactly the incumbent seam's nonpositive-drift conclusion). Per-step exit weight is dominated through the region values (exit domination), so for  $c < 1$  and any window  $[T, T']$ , the geometric series gives the truncation bound  $\kappa c^T \langle m_0, V \rangle / (1 - c)$  and — via the exact arithmetico-geometric identity (`sum_range_mul_pow_mul_eq`) and its tail estimates (`sum_Ico_pow_le`, `sum_Ico_mul_pow_le`) — the time-weighted first-moment tail  $\kappa \langle m_0, V \rangle c^T (T(1 - c) + c) / (1 - c)^2$ , both in universally-quantified partial-sum form: over  $\mathbb{Q}$  the limit need not exist, and any completion-valued normalizer, expected-value numerator, or moment row inherits the bound (`wmassAt_exit_tail_le`, `wmassAt_exit_moment_tail_le`). Dropping  $c < 1$  from a tail claim is unsound, not vacuous — at  $c = 1$  the rational division convention would make the assembled bound false (the battery's witness) — which is why the strict-contraction demand binds exactly where a tail-shaped claim row is spent.

**Corollary (bare alive-mass tail — the derived conversion).** Where  $\mu = \min_A V > 0$ , apply the unit-floor lemma to the rescaled certificate  $V/\mu$  (contraction and no-re-entry are scale-invariant; the floor  $V/\mu \geq 1$  on  $A$  holds by definition of  $\mu$ ):

$$\text{mass}_t(A) \leq c^t \langle m_0|_A, V \rangle / \mu$$

(`massAt_expect_on_le_of_regionContraction`, `dtmcAliveTail_of_regionContraction`) — the stored-row form of the hitting-time tail  $\Pr[\text{hitting time} > t] \leq M c^t$ . The conversion constant  $1/\mu$  is DERIVED, never stored: a stored constant would be a forgeable derived quantity. Both added hypotheses are witnessed load-bearing by kernel-checked countermodels committed beside the lemmas and re-checked every build: without the floor, one state at  $V = 1/2, c = 1$  makes the bound read  $1 \leq 1/2$  (`aliveTail_needs_floor`); without the closed complement, two states with the exterior feeding the region at probability one make it read  $1 \leq 0$  at  $t = 1$  (`aliveTail_needs_no_reentry`). With stochastic rows at every region state, an initial probability measure,  $0 \leq c < 1$ , no re-entry, and the positive minimum, weighted decay converts to bare survival decay and forces termination mass exactly one — the fourth claim relation; a sign-free weighted contraction alone would NOT suffice (the negative-weight self-loop countermodel is a battery tooth).

**Subsumption (the strengthening's extra obligation).** Mechanized twice over, as a strengthening of a landed seam must be: the instance chain — the weighted core at  $s \equiv 1$  on a stochastic kernel re-derives the previously proven stochastic core's exact statement (`massAt_expect_le_of_contraction_of_weighted`) — and the composed theorem (`qGenFormContraction_subsumes_genform`): from the incumbent's recomputed nonpositive generator form, the strengthened engine at the degenerate face (score  $\equiv 1, c = 1$ , region = all states) derives the incumbent consumption's exact path-law conclusion through the duality bridge, never by citing the incumbent's own proof. Every certificate admitted under the incumbent therefore discharges under the strengthening with an unchanged conclusion; the incumbent's rows, wire shape, and consuming lemmas are untouched.

**Prologue offsets.** The offset datum  $k$  (absent = 0) excludes a deterministic prologue from the claim window: partial survival sums index from  $k$ , and where a partial or expected-value claim spends it, the well-formedness demand recomputes prologue determinism — killed-on-exit evolution from the full stored initial measure with total surviving mass exactly one at step  $k - 1$  ( $k = 0$  vacuous). An unearned offset would shift the tail window onto mass the induction never controlled; the recompute refuses it.

*Remark R96.1 (status).* The finite face's schema is baked (entity, weight relation, demand, and the four named claim relations quoted in this section); the whole species' soundness, the subsumption pair, and the alive-mass face are mechanized sorry-free at standard axiom closure, axiom-audited on every build, with the species' mutant battery run as committed throwaway edits, each red at its predicted load-bearing step. No Lean statement is bound into this book yet: the binding column is honest open debt. The template and pattern faces are NOT part of this revision — their collapse warrants and the necessity witness for the eventual profile-length demand are mechanized and banked, and the faces board the revision that follows their own design work; until then template- and pattern-shaped claims live outside the certified lane, labeled as such.

## 15.13 The Soundness Theorem

*Its content is three conformance obligations on derivation edges, and together they are what turns the page's per-rule relative soundness lemmas — each proved on the hypothesis that the base calculus is sound — into a single verdict about a whole certificate, unconditional once those per-rule lemmas, base soundness, and the loader's conformance passes are supplied.*

### Rule 97. PROOFWELLFORMEDNESS (edge discipline (glue))

baked as *typing*, not as a node sort: E1 — derivation premises are judgment kinds XOR inherited Proof, never QProof, never a rule sort (the baked proof-node sorts' premise fields carry exactly these types); E2 — certificate-data references are not derivation edges; E3 — the admittedness + acyclicity pass over the certificate's own row graph (loader conformance, deliberately a check rather than a theory axiom: a cyclic certificate would chase-satisfy every axiom while proving nothing).

#### Lean statement

The discipline, mechanized at exactly the certificate-object level the recipes state it. The certificate shape binds by display — the four definitions ARE the E1/E2 typing claims — and the theorems bind as statements: the E3 bridge, the induction template in well-founded and finite-acyclic forms with root corollary, and the consumption-site transport pair. The induction theorem proper (towerCitation\_sound\_of\_wf) closes under no axioms at all.

BernsteinLogicAux.Acceptance . **acyclic\_wellFounded**

statement bound

```
-- **The E3 bridge**: on a FINITE certificate, the loader's checkable
acyclicity pass yields exactly the well-foundedness the induction needs.
This is why E3 can be loader conformance rather than an axiom of the
theory: well-foundedness is an induction principle the logical framework
deliberately lacks, but on finite row sets it is equivalent to the
decidable absence of citation cycles. -/
theorem acyclic_wellFounded [Finite ι] (C : ι → Row σ J ι)
  (hacyc : Acyclic C) : WellFounded (cites C)
```

BernsteinLogicAux.Acceptance . **towerCitation\_sound\_of\_wf**

statement bound

```
-- **rec:tc-template`, well-founded form** – the extension-edge
induction, in the shape the reflection theorem's induction consumes.
Hypotheses are the template's clauses: clause 1 = `hbase` (base
soundness; in deployment, the BL checker-soundness frontier – residue
R4); clause 2 = `hside` + `hstep` (the acceptance relation's local-check
clause as its own parameter, then the per-rule conditional-soundness
step in the cookie-cutter shape – the per-rule lemmas are CONSUMED here,
never proven: residue R1); clause 3 = `hwf` (the well-foundedness the E3
pass buys via `acyclic_wellFounded`). Conclusion: every admitted row's
conclusion-denotation holds – at each row the induction hypothesis
supplies exactly what the per-rule lemma consumes, and clause 1 grounds
the leaves. -/
theorem towerCitation_sound_of_wf
  (C : ι → Row σ J ι) (baseTrue : σ → Prop) (sem : J → Prop)
  (SideOK : ι → Prop)
  (hbase : ∀ i s, C i = Row.base s → baseTrue s)
  (hside : ∀ i, SideOK i)
  (hstep : ∀ i prems concl, C i = Row.ext prems concl → SideOK i →
    (∀ j ∈ prems, Row.holds baseTrue sem (C j)) → sem concl)
  (hwf : WellFounded (cites C)) :
  ∀ i, Row.holds baseTrue sem (C i)
```

BernsteinLogicAux.Acceptance . **towerCitation\_sound**

statement bound

```
-- **rec:tc-template`, headline form** – the discipline as the checker
consumes it: a FINITE certificate whose citation graph passes the E3
acyclicity check, base soundness, local checks, and the per-rule
conditional lemmas jointly warrant every admitted row's
conclusion-denotation. This is the theorem that turns the book's
per-rule RELATIVE soundness lemmas into an unconditional verdict about
a whole certificate. -/
```

```

theorem towerCitation_sound [Finite ι]
  (C : ι → Row σ J ι) (baseTrue : σ → Prop) (sem : J → Prop)
  (SideOK : ι → Prop)
  (hbase : ∀ i s, C i = Row.base s → baseTrue s)
  (hside : ∀ i, SideOK i)
  (hstep : ∀ i prems concl, C i = Row.ext prems concl → SideOK i →
    (∀ j ∈ prems, Row.holds baseTrue sem (C j)) → sem concl)
  (hacyc : Acyclic C) :
  ∀ i, Row.holds baseTrue sem (C i)

```

BernsteinLogicAux.Acceptance.towerCitation\_root

statement bound

```

/-- **Root soundness** (the acceptance relation's clause-4 shape): if
some admitted row of an accepted certificate concludes the root
judgment, that judgment's denotation holds. The abstract skeleton of
the reflection theorem's statement. -/
theorem towerCitation_root [Finite ι]
  (C : ι → Row σ J ι) (baseTrue : σ → Prop) (sem : J → Prop)
  (SideOK : ι → Prop)
  (hbase : ∀ i s, C i = Row.base s → baseTrue s)
  (hside : ∀ i, SideOK i)
  (hstep : ∀ i prems concl, C i = Row.ext prems concl → SideOK i →
    (∀ j ∈ prems, Row.holds baseTrue sem (C j)) → sem concl)
  (hacyc : Acyclic C)
  {Jroot : J} (hroot : ∃ i prems, C i = Row.ext prems Jroot) :
  sem Jroot

```

BernsteinLogicAux.Acceptance.citePos\_sound

statement bound

```

/-- **`prop:tc-consume` (a), positive citations**: the child's concluded
region `R` under-approximates its formula's denotation `D`, and any
MONOTONE consuming claim proved over `R` transfers to `D`. Which
operators are monotone in which positions is each consuming rule's own
lemma's business; this lemma fixes only the direction. A certificate can
lose completeness at a citation, never soundness. -/
theorem citePos_sound {X : Type*} {R D : Set X} {P : Set X → Prop}
  (hmono : Monotone P) (hsub : R ⊆ D) (hR : P R) : P D

```

BernsteinLogicAux.Acceptance.citeCmpl\_subset

statement bound

```

/-- **`prop:tc-consume` (b), the orientation swap**: an
under-approximating certified region's complement OVER-approximates the
denotation's complement – the conservative direction where regions
appear negatively. (Set-inclusion twin of
`BernsteinLogic.Structural.compl_over_approx`, which states the same
direction through the compiled region-judgment reading.) -/
theorem citeCmpl_subset {X : Type*} {R D : Set X} (hsub : R ⊆ D) :
  Dc ⊆ Rc

```

BernsteinLogicAux.Acceptance.citeCmpl\_sound

statement bound

```

/-- **`prop:tc-consume` (b), consumer form**: an ANTITONE claim proved on
the citable complement `Rc` covers the true violation set `Dc` – a
premise row proved on, or a probability bound proved for reaching, the
over-approximation covers the truth. -/
theorem citeCmpl_sound {X : Type*} {R D : Set X} {P : Set X → Prop}
  (hanti : Antitone P) (hsub : R ⊆ D) (hR : P Rc) : P Dc

```

BernsteinLogicAux.Acceptance.Row

definition bound

```

/-- **E1, as a type**: one row of a decoded certificate. A `base` row is a
base-calculus proof leaf concluding the sequent `s` (the `⊢` side); an
`ext` row is an extension row carrying its premise slots – references to
other rows, the derivation edges, and nothing else – and its concluded
satisfaction judgment (the `⊨` side). A premise slot can land on nothing
but another admitted row, consumed as that row's conclusion. -/

```

```

inductive Row (σ J ι : Type*) where
| base (s : σ)
| ext (prems : List ι) (concl : J)

```

BernsteinLogicAux.Acceptance . Row.cited

definition bound

```

/-- **E2, in one definition**: the derivation edges out of a row are its
premise slots and nothing else – the induction metric counts these only.
Certificate-data references (shared certificate families, lattice
objects) are unrepresented here by design; their erasure is the loader's
conformance obligation, not this module's. -/
def Row.cited : Row σ J ι → List ι
| .base _ => []
| .ext prems _ => prems

```

BernsteinLogicAux.Acceptance . Row.holds

definition bound

```

/-- The denotation of a row's CONCLUSION, under a kernel semantics
`baseTrue` for base sequents and a judgment semantics `sem` (the
judgment-denotation interface, kept abstract – zero measure theory in
this module by design). The two-case shape is E1's XOR: an edge lands on
kernel truth or on a judgment denotation; there is no third thing to
cite. -/
def Row.holds (baseTrue : σ → Prop) (sem : J → Prop) : Row σ J ι → Prop
| .base s => baseTrue s
| .ext _ concl => sem concl

```

BernsteinLogicAux.Acceptance . cites

definition bound

```

/-- Row `j` is cited by row `i`: a derivation edge from `i` down to `j`.
The well-founded induction descends along this relation. -/
def cites (C : ι → Row σ J ι) (j i : ι) : Prop :=
j ∈ (C i).cited

```

BernsteinLogicAux.Acceptance . Acyclic

definition bound

```

/-- **E3's checkable half**, as the induction consumes it: no row
transitively cites itself. On a finite certificate this is precisely
acyclicity of the citation graph – the decidable pass the loader runs. -/
def Acyclic (C : ι → Row σ J ι) : Prop :=
∀ i, ¬ Relation.TransGen (cites C) i i

```

## Correspondence (Steele display ↔ Lean)

### NO CORRESPONDENCE DICTIONARY YET

no reviewer-certified dictionary maps the displayed rule onto the mechanized statements above; until one is written and certified, that mapping rests on this section's editorial care alone.

## Lean verifier receipts

module BernsteinLogicAux.Acceptance; bound build e78746b9f98a... (bound from receipt 3d1fca564d6e11dc, 2026-07-20T03:41:07Z). A receipt records that named checking layers accepted a build: (module, compiled-artifact SHA-256, environment SHA-256, checker layers), minted when the checking gate ran; the store receipts attesting the bound build are listed with the layers each run credited. Nothing here asks the reader to trust the store: every layer is an independently runnable program over the quoted sources — rebuild the module and re-run the checkers to reproduce the verdict. Receipts attesting superseded builds credit no layer and are omitted from this rendering (the count of omissions, if any, is noted below).

| receipt          | minted               | layers                             | status  |

decorrelated (lean4export + nanoda (decorrelated kernel)) **current**

**comparator: none** no fixture in the three-implementation comparator harness (compiled / kernel-interpreted / reference-interpreted) exercises this rule.

## HOL4 statement

### OUT OF SCOPE BY DESIGN

Out of scope by structure: there is no rule statement to port — the discipline concludes nothing and has no check function of its own. Its one checkable obligation, the admittedness + acyclicity pass, is certificate-loader conformance, which would arrive with a HOL-side extension-theory loader as conformance code, not as a rule check. Independently, the HOL4 development's object today is the base calculus's wire-format checker (theory bern\_catalogue, the base catalogue's check-function cone); no extension-theory HOL development exists for such a pass to live in.

## HOL verifier receipts

### NONE

no HOL verification receipt exists for this rule.

## Proof

Genre: edge discipline (glue) — the extension page's fourth category, deliberately outside the three tiers. This entry is not a rule: it has no conclusion judgment, so “semantic soundness of the conclusion” does not type-check against it, and it has nothing to unpack, so neither rewriting genre applies — it *is* the unpacking mechanism. What it owes the book instead is the warrant every other section of the extension page silently leans on: each rule's soundness lemma is proved *relative* to base soundness, and this discipline is how those conditional lemmas compose into a single verdict about a whole certificate — unconditional once the per-rule lemmas, base soundness, and the loader's conformance passes are in hand; the closing remark names what remains conditional. The presentation apes the recipe form: the general induction template, then the discipline's obligations as the instance that makes the template apply.

**Recipe R97.1** (what the discipline licenses). A concluded child judgment  $\mathcal{M}$ ,  $x_0 \in R \models \varphi_{\text{child}}$  (the region-level satisfaction kind: every point of  $R$  satisfies  $\varphi_{\text{child}}$ , with  $R$  under-approximating the formula's denotation) makes  $R$  *citabile* as a region atom in any parent row's scope or target. The working example: a nested probability former  $\text{SProbGE}(p, \psi)$  (surface syntax  $P_{\geq p}[\psi]$ ) inside a state formula compiles its child first and cites the child's concluded region as the sublevel atom  $\{V_{\text{child}} \leq 1 - p\}$ . The license is an *edge* between rows of one certificate, never a node: the citation itself concludes nothing.

**Recipe R97.2** (the induction template). Let a certificate be a finite set of admitted rows: base-calculus proof rows (leaves, concluding sequents on the  $\vdash$  side) and extension rows (concluding satisfaction judgments on the  $\models$  side), each extension row's premise fields referencing other rows; call a row *admitted* when its local checks pass — its premise fields are well typed and its side conditions recompute true. Suppose:

1. *base soundness* — every admitted base row's sequent is true in kernel semantics;
2. *per-rule conditional soundness* — for every extension rule sort  $R$  a lemma  $\text{sound}_R$ : if the referenced child judgments' denotations hold, the base leaves are true, and the side conditions recompute true, then the concluded judgment's denotation holds;
3. *acyclicity* — the certificate's citation graph is acyclic.

Then every admitted row's judgment denotation holds: induct over the citation order, which clause 3 (with finiteness) makes well-founded; at each row the induction hypothesis supplies the child denotations, admittedness supplies the recomputed side conditions, and clause 1 grounds the leaves — together exactly what clause 2's lemma consumes. The conditional lemmas are the per-rule sections of this book; the induction is this section.

**Recipe R97.3** (the instance — the discipline's three obligations). The discipline is staged as *typing and conformance*, not as a node sort, in three obligations, each of which is one premise of Recipe R97.2 made checkable:

- **E1 (edge typing).** Every premise field of an extension row is typed as a satisfaction-judgment kind or as an inherited base-proof leaf, exclusively — never as a raw rule row of either theory. This makes the induction's case analysis exhaustive: every edge lands on something clause 1 or the induction hypothesis covers; no edge can cite an object that has no soundness account.
- **E2 (data/edge separation).** Certificate-*data* references — a certificate family reused across rows, a lattice object — are not derivation edges. The induction metric counts derivation edges only, so shared data can neither smuggle a cycle past the acyclicity pass nor impose ordering the derivation structure does not have.
- **E3 (admittedness + acyclicity).** A loader pass over the certificate's own row graph checks that every referenced row is admitted and that the citation graph is acyclic — clause 3 verbatim. This is *conformance*, deliberately not an axiom of the theory: an existence-of-concluding-proof axiom would let the theory's own saturation fabricate proof rows, and well-foundedness is an induction principle, which the logical framework deliberately lacks. A cyclic certificate would satisfy every local check while proving nothing — or worse: take two rows, each citing the other's concluded judgment as its sole premise, with per-rule lemmas of the shape  $J_B \Rightarrow J_A$  and  $J_A \Rightarrow J_B$ . In an instance where both judgments are false, both implications hold, every per-row obligation and the admittedness pass discharge, and only acyclicity objects; accepting the pair would not merely warrant nothing — it would assert falsehoods.

**Proposition R97.4** (consumption-site soundness). *Let the child conclude  $\mathcal{M}$ ,  $x_0 \in R \models \varphi$  with  $R \subseteq \llbracket \varphi \rrbracket$ . Then at every consumption site the citation is used in the sound direction:*

- (a) *a positive citation passes  $R$  exactly, and any monotone claim over  $R$  (“the state reaches / remains in  $R$ ”) entails the same claim for  $\llbracket \varphi \rrbracket$ ;*
- (b) *a complement citation swaps orientation:  $\text{cmpl}(R) \supseteq \text{cmpl}(\llbracket \varphi \rrbracket)$ , so a premise row proved on  $\text{cmpl}(R)$  — or an upper probability bound proved for reaching it — covers the true violation set.*

*Proof.* (a) is monotonicity of the consuming operator in  $R \subseteq \llbracket \varphi \rrbracket$ ; (b) is the same inclusion complemented. The discipline contributes exactly this inclusion and its swap; *which* operators are monotone in which positions is each consuming rule's own lemma's business, stated and proved in that rule's section. Under-approximation on the positive side and over-approximation on the complement side are both conservative: a certificate can lose completeness at a citation, never soundness.  $\square$

**Remark R97.5** (why this is not a rule, and what the mechanization is). The three tiers each predicate on a conclusion: core is the concluded judgment's semantic soundness; admissible and alias are verified unpackings of a concluded node. A discipline with no conclusion satisfies none of the three definitions — it is the induction step the tiers' lemmas plug into, which is why it renders under its own category head rather than wearing a tier that does not type-check. Its one *checkable* obligation (E3) lands as certificate-loader conformance code. The warrant itself is now mechanized at exactly the certificate-object level this section's recipes state it (BernsteinLogicAux/Acceptance.lean), anchor by anchor: Recipe R97.2 is `towerCitation_sound` — well-founded induction over admitted rows, consuming the per-rule lemmas as its step hypothesis — in finite-acyclic (headline) and well-founded forms, with root corollary `towerCitation_root`; the E1 typing of Recipe R97.3 is the row type itself, so the exhaustiveness of the induction's case analysis is type-checked (two consumptions exist: kernel truth of a base leaf, denotation of a concluded judgment — no third case to cite); E2 is the edge metric `Row.cited` (premise slots only); E3's sufficiency is the bridge `acyclic_wellFounded` — on a finite certificate the checkable acyclicity pass yields exactly the well-foundedness the induction needs, which is why conformance suffices where the logical framework deliberately lacks an induction axiom; and Proposition R97.4 is the transport pair `citePos_sound` / `citeCmpl_subset` / `citeCmpl_sound`. The induction theorem proper (`towerCitation_sound_of_wf`) depends on no axioms at all; the bridge and transport lemmas close under the standard three.

**Remark R97.6** (what remains conditional, named). This discipline's mechanization is conditional on named residues rather than a vague gap. **R1** — the per-rule lemmas enter the induction as a hypothesis: that is the discipline's literal content (it composes conditional lemmas; it does not prove them), but the type-level identification of that hypothesis's instances with this book's bound per-rule statement family awaits the deep embedding and the per-rule schema wrappers; until then the identification is editorial, rule by rule. **R2** — E2 is discharged by *representation*: the abstract row type carries derivation edges only, and the faithfulness of the concrete certificate format's erasure onto it (no derivation edge lost, no data reference kept) is loader/decode conformance, outside the module. **R3** — admittedness (E3's first half) is absorbed by the totality of the abstract certificate's indexing: every reference IS an admitted row, by type; the loader's admittedness check is what establishes that totality. (Clause 1, base soundness, is the base calculus's own soundness frontier and enters as the named hypothesis it always was — a premise of the template, not a residue of the mechanization.)

# Partial Completeness

Every rule in the catalogue of chapter 15 carries its own soundness story: a statement, a proof, and, where mechanization has caught up, a machine-checked realization. Soundness can therefore be audited locally. Each rule earns its keep on its own, and a user who trusts the kernel need trust nothing else.

Completeness makes a different kind of claim, and no amount of local auditing can establish it. A completeness theorem says that the rule set as a whole is not missing anything, so that every true entailment expressible in some class of specifications is actually derivable. Claims of that shape must be won fragment by fragment, by exhibiting either a derivation or a countermodel for every specification the fragment can express. The prize is a change in the meaning of refusal. Without completeness, a tool that fails to derive a specification reports only that a rule might be missing; within a complete fragment, the same failure delivers a definite verdict about the specification itself.

This chapter records what has been proved. A reader who wants only the shape of the result can stop after the completeness theorem (Theorem 16.4); the axiom basis in section 16.1.1 shows what completeness costs, and the closing sections account for the evidence and draw the boundary of the claim. The most surprising idea in the chapter, for a reader browsing, lives in Remark 16.5 and in Figure 16.1: the models that witness completeness must branch, even though nothing in the specifications mentions branching.

## 16.1 A complete fragment: hard deadlines under staggering

The fragment lives in the timed core of the calculus and uses two modalities over propositional logic.

**Definition 16.1** (clocked model). A *clocked model* has finitely many locations, each carrying a positive maximal dwell time and a fixed valuation of the atoms. A *trajectory* is a timed path through locations that respects the dwell bounds.

The two modalities read as follows.

- $\Box\varphi$ , *invariance*:  $\varphi$  holds at every point reachable from here. The formula  $D := \Box\perp$  (“deadness”) holds exactly at the states with no future, so  $\neg D$  asserts liveness.
- $A_T\varphi$ , *worst-case service*: every trajectory from here reaches a  $\varphi$ -point within time at most  $T$ . The quantifier ranges over all branches, so the operator reports a worst case rather than a per-path promise. That one word, “every”, is the source of everything difficult below.

The characteristic constraint of the fragment, and the origin of its working name, is the *gnand*<sup>1</sup>, a globally held prohibition of joint imminence:

$$\text{gnand}(a, d_a, b, d_b) := \Box\neg(A_{d_a}a \wedge A_{d_b}b),$$

read: at no reachable moment is  $a$  due within  $d_a$  while  $b$  is due within  $d_b$ . It serves as a natural mutual-exclusion primitive for services that must stay temporally staggered, two operations that may never both be imminent, in either order.

<sup>1</sup>“Graded NAND”: a prohibited conjunction, as in NAND, whose conjuncts are graded by time bounds. The name arose as a working label during the development and proved too convenient to retire.

**Example 16.2** (a single-boiler espresso machine). A single-boiler espresso machine cannot brew and steam at the same time. Suppose an espresso order  $e$  must be served within 90 seconds on every branch of the schedule, a milk order  $m$  within 120, and the boiler forbids any reachable moment at which both are due within 30 seconds. The specification comprises the pending obligations  $\neg e \wedge A_{90} e$  and  $\neg m \wedge A_{120} m$ , the staggering constraint  $\text{gand}(e, 30, m, 30)$ , and liveness  $\neg D$ . Suppose the café also advertises that the 90-second figure is tight, so that some branch really does take the full 90. That assertion,  $\neg A_{89} e$ , already forces the schedule to *branch*: a barista who always serves promptly would make the worst case better than declared, so some branch of the schedule must dawdle while another serves. This innocent observation grows into the central construction of the completeness proof (Remark 16.5).

The example's shape, in general, defines the fragment.

**Definition 16.3** (g<sub>and</sub> core). A *g<sub>and</sub> core* is a specification asserting, over  $n$  atoms:

- **pending obligations**  $\neg a \wedge A_{s_a} a$ , meaning  $a$  has not yet been served and must be served within  $s_a$  on every branch;
- optionally, **exactness**  $\neg A_{s_a-1} a$  (the deadline is tight: some branch delays past  $s_a - 1$ ) or an **avoidance fact**  $\neg A_h a$  (some branch withholds  $a$  through time  $h$ );
- any finite set of g<sub>and</sub> constraints over pairs of atoms; and liveness  $\neg D$ .

Deadlines may be taken to be integers with no loss of generality.<sup>2</sup>

The fragment deliberately excludes triggered obligations  $\Box(x \rightarrow A_d y)$ , the atom-level variant of the staggering constraint, and possibility assertions  $\neg \Box \nu$  with their associated time-locks. The boundary is principled rather than incidental; it follows a *sign*. Every constraint in the fragment either forbids joint imminence or states a fact at the initial state, and the model construction below is protected by a monotonicity lemma that holds for such negative-side checks. The excluded formers *demand* positive worst-case facts at interior states of a model. Constructions that meet such demands exist in the development record, but their completeness theory is open, and this section claims nothing about them.

### 16.1.1 The proof theory

The axiom basis was not designed in advance; it was *discovered*, by iterating between attempted completeness proofs and machine searches for countermodels. Three axiom schemata were added to the seed basis this way, each certified genuinely new by an explicit independence witness before being adopted, and several others were pruned as derivable. The final basis comprises:

- four axioms governing the invariance modality;
- reflexive service,  $\varphi \rightarrow A_T \varphi$ ;
- budget composition,  $A_{T_1} A_{T_2} \varphi \leftrightarrow A_{T_1+T_2} \varphi$ ;
- the graded absurdity law,  $A_T \perp \rightarrow D$ ;
- relativization of obligations through invariants,  $\Box \nu \wedge A_T (\chi \wedge \nu) \leftrightarrow \Box \nu \wedge A_T \chi$ ;
- a first-service law: at the first service among  $n$  co-pending obligations, the remaining obligations still bind; and
- the last and decisive addition, a *residual-split* first-service law. For any cutoff  $c$  strictly below all deadlines,

$$\bigwedge_{i \leq n} A_{T_i} \alpha_i \rightarrow A_c \left( \bigvee_i (\alpha_i \wedge \bigwedge_{i' \neq i} A_{T_{i'}} \alpha_{i'}) \vee \bigwedge_i A_{T_i-c} \alpha_i \right),$$

meaning that within  $c$ , either some first service has occurred (and the co-obligations persist), or nothing has been served and every obligation holds at its true residual  $T_i - c$ .

Derivation rules are propositional calculus, modus ponens, import of a background theory, monotonicity for both modalities, and rational rescaling.

<sup>2</sup>Rational rescaling and the decomposition of a deadline into iterated unit deadlines are derivable rewrites in the proof theory, so a fractional menu of deadlines reduces to an integer one.

### 16.1.2 The completeness theorem

**Theorem 16.4** (completeness for the gnand fragment). *For gnand cores, the following are equivalent:*

1. *the core is satisfiable in a clocked model;*
2. *an effective arithmetic on the core (a fixpoint computation on per-atom effective deadlines and service-precedence edges, with one additional branch-conditional check) fires none of its refutation conditions;*
3. *an explicit finite model of the core exists on the uniform grid with dwell  $\frac{1}{n+1}$ , where  $n$  is the number of pending atoms, and the theorem's proof constructs it;*
4. *the core is consistent:  $\nVdash D$  from the core in the basis above.*

In particular, derivability and clocked validity coincide on the fragment. Since soundness is proved over a much broader class of trajectory spaces, of which clocked models are a special case, validity over every intermediate semantic class coincides with both. Satisfiability and validity of cores are therefore *decidable*, not merely semi-decidable; the fixpoint arithmetic of item (2) decides both.

Within its fragment the theorem is unconditional; its statement carries no unproven hypotheses. Its proof, however, forms a chain with several links, and the accounting must proceed link by link. That every arithmetic refutation in item (2) is matched by a formal derivation of  $D$  is a theorem, with the residual-split law doing the work its adoption promised: the arithmetic's deadline-tightening step is derivable by iterating the law at successive cutoffs, descending step by step to the arithmetic's own value. That every arithmetic-feasible core yields a model at grid  $\frac{1}{n+1}$  combines a proved monotone-protection lemma with one combinatorial schema whose verification is per-instance and population-scale (section 16.1.3) rather than symbolic.

*Remark 16.5* (delayer wings). The model construction deserves a name of its own. The emitted models are *schedule trees*: an earliest-deadline-first spine together with *delayer wings*, auxiliary branches whose only role is to keep each declared worst case at its declared value, so that the negative graded facts remain true even though every individual path serves early (Figure 16.1). That branching structure can satisfy staggering constraints which every branching-free model provably violates. This was the central semantic discovery of the development, and it is why the fragment's models are trees rather than runs.

### 16.1.3 Evidence and assurance status

The proofs are prose mathematics, developed against an unusually dense instrument battery. The completeness chain itself is not yet mechanized in a proof assistant. The three axiom schemata the search added, however, now carry sorry-free machine-checked soundness lemmas (`sound_u10f`, `sound_firstService`, and `sound_fsResidual`, in `Qtsl/TimedCore.lean` under `lean/qtsl` in `maitria-coalition/qtsl`; their statements are reproduced in Appendix A). A machine-checked countermodel, `firstService_attainment_necessary`, accompanies them. The two first-service lemmas assume two properties of the trajectory space, fusion closure and attainment of first service; clocked models satisfy both. The countermodel shows that the attainment hypothesis cannot be dropped, by exhibiting a fusion-closed space in which the first-service

Figure 16.1: A schedule tree for the espresso core of Example 16.2. The solid spine serves early, in earliest-deadline-first order. The dashed delayer wing dawdles, so that the worst-case service time of  $e$  really attains the declared 90 seconds and the exactness assertion  $\neg A_{89} e$  comes out true. No single run can do both jobs; the tree does.

schema's premises hold and its conclusion fails. Rule-level mechanization otherwise tracks the catalogue's own realization discipline (chapter 15). The machine evidence behind the chain, all of it replayable from the development record as it migrates to `maitria-coalition/qtsl`:

| instrument         | what it checks                            | result                           |
|--------------------|-------------------------------------------|----------------------------------|
| derivation sweep   | arithmetic-refuted cores derive $D$       | 64,786 cells, 0 underivable      |
| cross-pair sweep   | the descent lemma's coverage              | 4,116/4,116 derived              |
| branch engine      | branch-conditional refutations derive $D$ | 1,000/1,000; cycle mode 200/200  |
| model emitter      | feasible cores yield grid models          | 122/122 named; 541/541 random    |
| soundness controls | no false derivations of $D$               | silent on every satisfiable core |

The controls in the last row did real work during the development. They caught two draft derivation engines asserting more than their machinery guaranteed, both retired before any proof consumed them, and the same battery falsified three earlier conjectured axiom bases outright. A rule set that has survived that regime differs, as an epistemic object, from one that has merely not yet failed.

#### 16.1.4 What is not claimed

Completeness is claimed for `g` and cores only. The composition of this fragment with triggered obligations and possibility constraints is open theory; so is the calculus's next expressive tier, in which worst-case service generalizes to a time-bounded *until* that carries safety clauses along the way. Minimality of the basis, a separate question from sufficiency, is settled for integer deadline menus (the residual-split law is genuinely underivable from the rest: there is a six-state witness, and six states is minimal) and open for arbitrarily fine fractional menus. No answer to the minimality question can weaken the theorem, since a redundant axiom would only mean that the same completeness holds from fewer assumptions.

# Tutorial: A Re-entrant Semiconductor Fab

---

DRAFT

The preceding chapters introduced the stack one layer at a time: mechanisms and their composition (chapter 12), the pattern inventory that composition ships as (chapter 13), the semantics that specifications are stated in (chapter 9), the plated-certificate discipline for token-population systems (section 10.4 and section 12.18), and the producer stack that finds certificates for a checker to replay (chapter 19). This chapter runs the whole stack over a single model, end to end: describe a factory line, declare it as database rows — an SDCPN, a stochastically and dynamically coloured Petri net in the modelling catalogue’s frame (section 12.18), which is the native habitat of everything that follows — recompose it along its natural seams, state what should be certified about it, and read the certificates. The certificates come in two families whose division of labour is stated rather than smoothed over. The primary family (section 17.5) certifies the discrete line itself, at its full combinatorial state space: exact statements holding along every run, at every lot count, under every resolution of the scheduling freedom — the variadic-certificate rows of section 12.18 at work on their first industrial subject, and then re-read on the wall clock, where the dispatch seat is priced end to end: a certified floor over every policy, the exact optimum and the supervisor family attaining it, a widened full-dispatch seat, an untrusted filler inside a certified envelope, and one certificate instantiated across six orders of magnitude of lot count. The second family (section 17.6) certifies the *fluid relaxation* of the same line: policy-indexed stability under sustained arrivals, at loads within a tenth of a lot per week of capacity — claims the discrete family does not yet price, which is why the fluid lane is retained in full as the comparison lane, with the contrast stated where the two families meet. A closing section then builds the fluid lane’s model on the toolkit’s TypeScript surface and drives its release grid back to checked certificates, in a listing that runs.

The model is the *Mini-Fab*: five machines in three stations, six route steps, every station visited twice per lot. It was posed by Kempf at Intel in 1994 as a deliberately minimal semiconductor-fab exercise and has circulated as a community benchmark since; the complete quantitative restatement that this chapter’s constants are witnessed against is van den Berk’s 2004 Eindhoven master’s thesis [17] (the systems engineering group of Rooda and Lefeber), whose second chapter restates the entire case. The spec digest recording that witnessing, decision point by decision point, is committed beside the certificates in the experiments repository (section 2.9).

Small as it is, the line exhibits the domain’s whole hard structure: re-entrant flow, a single-machine bottleneck, batching with mix constraints, sequence-dependent setups, personnel shared across stations, maintenance calendars, and machine failures that destroy work in progress. And its headline claim family has teeth, because it is famously falsifiable: re-entrant lines can destabilize strictly below nominal capacity under plausible dispatch policies (the Kumar–Seidman phenomenon [145]), so “this policy keeps the line stable at this load” is a claim the world is entirely capable of refuting.

## 17.1 The line

Three workstations process lots of wafers. *Diffusion* has two furnaces, a buffer for 18 lots, and consumes its input in batches of exactly three lots. *Implantation* has two machines and a buffer for 12. *Lithography* has one machine and a buffer for 12. Every lot follows the same six-step route — diffusion, implantation, lithography, implantation, diffusion, lithography — so each station is visited twice, running a “low” recipe on a lot’s first visit and a “high” recipe on its second:

Figure 17.1: The Mini-Fab's re-entrant route. Buffers are drawn in route order (top); the three stations (bottom) each serve two non-consecutive steps, which is what *re-entrant* means — the crossing connectors are the route folding back on itself. Lithography runs both of its steps on a single machine and is the line's bottleneck. Utilizations are the deterministic machine-occupancy figures at the nominal release of 84 lots/week.

| step | station      | recipe | process (min) | load (min) | unload (min) |
|------|--------------|--------|---------------|------------|--------------|
| 1    | diffusion    | low    | 225           | 20         | 40           |
| 2    | implantation | low    | 30            | 15         | 15           |
| 3    | lithography  | low    | 55            | 10         | 10           |
| 4    | implantation | high   | 50            | 15         | 15           |
| 5    | diffusion    | high   | 255           | 20         | 40           |
| 6    | lithography  | high   | 10            | 10         | 10           |

Loading and unloading hold the machine; at diffusion they are paid per *batch* of three, not per lot. There is no preemption and no rework.

Three product types are released on constant per-type intervals: 3 test lots, 51 of type A, and 30 of type B per week of  $7 \times 1440 = 10080$  minutes — 84 lots/week in all. One release interval is worth pausing on: type A arrives every  $10080/51 = 3360/17$  minutes. The parameters are all integers, and still the event times of the system are not, so exact rational time arithmetic is a necessity rather than a nicety, and the declared model keeps every duration in  $\mathbb{Q}$ . Arrivals are deterministic; the only stochastic elements anywhere in the specification are implantation failures and repairs (below).

Around the route sit the resources that make the model interesting. One *transporter* (capacity one lot, 4 minutes per move between adjacent areas, 1 minute to load or unload) carries every lot between stations. Two *operators* perform all machine loading and unloading, non-preemptively: operator 0 serves diffusion and implantation, operator 1 serves lithography and implantation, so implantation is contested and every station's handling competes with another station's. Lithography additionally pays a sequence-dependent *setup*, performed by an operator with the machine empty, whenever its input changes against the previous job: 5 minutes for a product-type change, 10 for a step change, 12 for both. At the two-machine stations, a *test* lot's second visit must use the machine it did not use on its first (so both machines stay monitored); a diffusion batch contains at most one test lot, and a high-step batch must not mix the two commercial types. Each operator takes three 60-minute off-blocks per 720-minute shift, placed freely. One *technician* performs scheduled maintenance (75 minutes per diffusion furnace per day; 30 and 120 minutes per shift-window at lithography and implantation respectively), and implantation machines *fail* during processing — time between failures uniform on  $[1440, 4560]$  minutes of processing time, repair uniform on  $[360, 480]$  — destroying the lot in process.

The capacity arithmetic that organizes everything downstream: per lot, lithography is occupied  $(10 + 55 + 10) + (10 + 10 + 10) = 105$  minutes on its single machine; diffusion  $95 + 105 = 200$  minutes spread over two furnaces (batch handling divided by three); and implantation  $60 + 80 = 140$  minutes over two machines. At 84 lots/week the three stations run at 87.5%, 83.3%, and 58.3% respectively — before setups and maintenance, and the margin shrinks from there. The single-machine lithography station is the bottleneck, and the line's deterministic fluid capacity is  $10080/105 = 96$  lots/week, lithography-pinned (Figure 17.1).

## 17.2 The model as rows

The declared model is a set of database rows — the Geolog substrate of chapters 3–5 — over the System vocabulary of chapter 12. The ground layer is nothing but the tables of the previous section, recorded as entities with attributes, in the entity-per-row idiom:

```

Station : Set;
Station/name      : Station -> Str;
Station/machines  : Station -> Nat;
Station/bufcap    : Station -> Nat;
Station/batch     : Station -> Nat; // machine-input batch size (1 = none)

// st_diff: "diffusion" 2 18 3; st_impl: "implantation" 2 12 1;
// st_lith: "lithography" 1 12 1

RouteStep : Set;
RouteStep/idx      : RouteStep -> Nat;
RouteStep/station  : RouteStep -> Station;
RouteStep/recipe   : RouteStep -> Str; // "low" | "high"
RouteStep/proc     : RouteStep -> Q; // minutes
RouteStep/load     : RouteStep -> Q; // handling; the machine is held
RouteStep/unload   : RouteStep -> Q;

// (1, diff, low, 225, 20, 40) (2, impl, low, 30, 15, 15)
// (3, lith, low, 55, 10, 10) (4, impl, high, 50, 15, 15)
// (5, diff, high, 255, 20, 40) (6, lith, high, 10, 10, 10)

SetupRule : Set; // lithography, sequence-dependent
SetupRule/typeChange : SetupRule -> B;
SetupRule/stepChange : SetupRule -> B;
SetupRule/minutes    : SetupRule -> Q;
// (t,f,5) (f,t,10) (t,t,12) (f,f,0)

FailRule : Set; // implantation only
FailRule/tbflLo : FailRule -> Q; FailRule/tbflHi : FailRule -> Q;
FailRule/repLo : FailRule -> Q; FailRule/repHi : FailRule -> Q;
// time between failures 1440..4560 (processing time); repair 360..480

```

Rows are data rather than code: nothing about these declarations commits to a decomposition, and both of the readings below compile their dynamics from the same ground tables.

The *monolithic reading* renders the whole fab as one mechanism — an SDCPN, and the class name is a parts list for exactly this specification, worth unpacking on first contact. *Places* hold coloured tokens: waiting lots (coloured by product type, release time, and first-visit machine), machine phases (setup, loading, busy, awaiting unload, unloading, maintenance, down), personnel and transporter phases, and a sink of finished lots. *Dynamically coloured*: every duration in the tables is a token colour in motion — a timer drifting at  $\dot{\tau} = 1$  inside its phase and forcing a jump at its threshold — so time lives in the colours, never in a side-calendar. *Stochastically*: implantation’s failure and repair durations are random firing measures on the reset, drawn from the declared uniform family — and nothing else in this specification is random. The transitions carry the guards and firing laws, and the thesis’s own release idiom — per-type signal generators firing at constant intervals — is the timer-mechanism idiom, so the model’s front door needs no vocabulary at all beyond what chapter 12 already provides. The net’s interface exposes *aggregate* coordinates only: counts and pools — work in progress, per-step queue lengths, busy-machine counts per station, a completed-lot count, and a pool summing realized flow times.

Three features of the specification look, at first sight, like they should resist an aggregate-count rendering. None of them does, and each dissolution is informative.

**Batching survives count coordinates.** A diffusion load consumes three same-step lots subject to joint colour constraints (at most one test lot; high-step batches commercially pure). At the aggregate stratum, “a feasible batch exists” is a finite disjunction of count inequalities — for the high step, with  $k_A, k_B, k_{\text{test}}$  the

per-type queue counts,

$$k_A \geq 3 \vee k_B \geq 3 \vee (k_{\text{test}} \geq 1 \wedge k_A \geq 2) \vee (k_{\text{test}} \geq 1 \wedge k_B \geq 2),$$

and the reset decrements the counts by the chosen composition. *Which* three lots form the batch is invisible to every aggregate observable, by exchangeability. What the guard does add is a *choice* among feasible compositions — which belongs to dispatch, below, not to a new row species. Machine dedication for test lots is likewise just a colour coordinate (the first-visit machine), with a mismatch guard on the second visit.

**FIFO dissolves into class-level dispatch.** The count grammar deliberately has no expression for “the  $i$ -th token,” so first-in-first-out order within a colour class is structurally invisible — and for this model the invisibility is semantically exact, not a compromise: service law depends only on a lot’s type and step, so permuting same-colour lots moves no count trajectory, no utilization or throughput observable, and (by Little’s law, which relates only means) not even mean flow time. What FIFO *does* determine that matters is which colour class a freed machine serves next — and that residue is a dispatch policy: the index of every certificate in the fluid lane (section 17.6), and a freedom the combinatorial certificates of section 17.5 instead quantify over — adversarially, every policy at once. The dissolution does have a boundary: per-lot flow-time *distribution tails* do depend on within-class order, so a specification demanding per-lot quantile bounds would reopen the question (an age coordinate — still a colour — is the natural extension).

**Simultaneity is the norm, not a corner case.** Every duration in the tables is an integer number of minutes measured from a common origin, so distinct timers reach their thresholds at the same instant constantly — every shift boundary fires off-block guards on three resources at once. The declared model therefore carries explicit serialization data for simultaneous forced jumps (a priority order on transition families, with commutation as the alternative discharge), and the reference simulator’s deterministic tie-break — time, then declared family order, then entity identity — is that serialization made executable. Two correct simulators that disagree under tie-reordering are answering the commutation question the serialization row exists to settle.

## 17.3 The compositional reading

The monolithic reading is complete and faithful, and it deliberately gives up the one thing the composition axis exists to buy: decomposition. A per-station argument, a per-resource invariant, a certificate that transports across a boundary — all of these want the fab as a *composite*: release generators, three station mechanisms, two operators, a technician, a transporter, and a sink, wired together. The seams come in four kinds — directed lot handoffs, resource-pool memberships, fused event ports, and the dispatch freedom the fusions create — and the pattern inventory they draw on is chapter 13’s.

What the seams are, mathematically, pattern by pattern:

**Directed lot flow.** A station’s completions, as a counted output, wired into the next station’s arrival input — token flow carried as signal flow, with the lot’s colours riding as a tuple. This is ordinary directed wiring. It has one limitation worth naming: conservation (a lot leaves diffusion if and only if it arrives at implantation) is a semantic property the wire itself does not state; in the compositional reading it is recovered where it matters, as the pool pattern’s invariant.

**Resource pools.** Operator 1 must be exclusively held by either a lithography task or an implantation task, never both; so must the technician, across three stations, and the transporter, across every handoff. Continuous signal-sharing carries none of this — there is no signal, only a conserved unit. The resource-pool pattern of chapter 13 renders each resource as a pool with *take/give* ports and a crossing discipline (each user declares which of its modes count as holding the unit), and its payoff is a theorem rather than a convention: for a well-formed pool share, every jump of the composite preserves

$$k_{\text{pool}} + \sum_{u \in \text{users}} \#H_u = C,$$

the count-row conservation invariant — free to the checker, since it is a linear invariant of the count coordinates. For this model,  $C = 1$  four times over: each of the four pools is a single human or vehicle.

**Event fusion.** “Load starts” is one event touching three parties: the machine (empty, set up), the buffer (a feasible batch present), and the operator (idle, at the station). The fusion pattern makes it one *joint jump*: enabling is the conjunction of the parties’ local guards evaluated on the pre-jump snapshot, each party writes only its own state (so reset commutation within the fusion is a theorem), and one party — here the station’s timer — owns the timing. Without fusion, every synchronized cluster collapses into a single mechanism, which is the monolithic reading by forced march; fusion is what lets the composite reading exist at all.

**Dispatch.** Fusion creates contention: a freed lithography machine with both step-3 and step-6 lots waiting; an idle operator with two stations bidding; a feasible-batch guard satisfiable by several compositions. Undispatched, the composite is nondeterministic, and the semantics resolves the freedom *demonically* — which is the correct default precisely because of Kumar–Seidman: “stable at this load, whatever resolves the contention” is typically false below capacity, and should be unprovable when it is false. A dispatch row installs a named policy — a chooser over the enabled-conflict set, reading aggregate observables. The two certificate families divide over exactly this freedom: each fluid certificate of section 17.6 is indexed by the (system, policy) pair, while the combinatorial certificates of section 17.5 leave the freedom demonic and hold under every resolution of it. The off-block placement freedom (operators schedule their own breaks) sits in the same slot: it is control data, not plant data.

**Distribution-valued resets.** Implantation’s failure and repair durations are uniform on rational intervals — noisy timer thresholds, neither deterministic resets nor exponential clocks. The declared form is a reset kernel from a named family (uniform[ $a, b$ ] here), consumed by the certification interface only through its exact rational moments. Fixed and uniformly-distributed durations make the count process semi-Markov; the timer-as-state discipline (the supplementary-variable construction) is what keeps the presentation Markovian in the extended state, so this is vocabulary, not new metatheory.

Here is where the two readings stand. The monolithic reading uses mechanism vocabulary alone — timers, coloured counts, guarded jumps; the combinatorial certificates of section 17.5 are stated against its token-population refinement (places as plates, lots as tokens), and the fluid certificates of section 17.6 against its aggregate projection. The compositional reading exercises the fusion, pool, dispatch, and reset-kernel patterns exactly as chapter 13 catalogues them; the fusion and pool patterns had been reserved as a future axis until this model arrived as their first customer and ended the deferral, and the composite row set is mid-flip from design to artefact — the fusion stratum’s producer surface has landed, the pool packaging has not, and section 17.7 draws that boundary where the code makes it concrete. Equally informative is what the model does *not* demand: no nesting, no mode-switched macro-locations (shifts are timer guards inside mechanisms), no credal wire content, and no delayed trace — until some future dispatch chooser reads *lagged* observables (yesterday’s throughput, smoothed work in progress), at which point the loop becomes observation-delayed feedback and lands in the delayed-trace pattern. A discrete-event benchmark exercises a largely disjoint slice of the vocabulary from the robotics and hybrid-dynamics exemplars the patterns were designed against, and it still lands on the catalogued inventory; that is evidence the inventory’s shape is holding.

One number quantifies what the composite seams own. The reference discrete-event simulation committed beside the model tables (semicon/minifab/sim in the experiments repository) implements the deterministic layers only — machines, batching, setups, dedication, first-in-first-out within colour — on an exact  $\frac{1}{17}$ -minute integer tick, and measures a deterministic-core throughput ceiling of 87 lots/week. The thesis’s full model — adding the personnel, transport, maintenance, and failure layers — measures a maximal FIFO throughput of 57.5 lots/week. The roughly thirty lots per week between those two numbers is carried by *exactly* the layers that live on the pool, fusion, and reset-kernel seams: a quantitative reading of how much of this line’s behaviour the composition patterns are responsible for.

## 17.4 The specification

What should be certified about a fab divides into two claim families, and the division is structural rather than stylistic: the two families quantify differently, are checked by different machinery, and fail differently.

The first family is *exact and pathwise*: claims about the discrete line itself, holding along every run, at

every lot count, under every resolution of the scheduling freedom. Conservation — machines neither minted nor lost; a lot census that nothing but a completed lot can decrease; a congestion measure that no firing increases; and hard progress — from any work-in-progress profile, a stated budget of transition firings that no scheduler can exceed. These are the apparent infinity “one claim per marking, one row per transition instance” collapsed to finitely many symbolic rows by the plate discipline (section 10.4), and section 17.5 certifies them. In the released specification vocabulary (chapter 14) every member of this family now renders. The safety members render as PAIways atoms over the model’s aggregate wires, and a worked render appears beside its certificate below. The hard firing-count member renders through the count-ceiling spelling,  $\text{SReturnLE}(B, \text{retFireCount}(R))$ : a sure bound on an event count was a catalogued deliberate absence of the language until the transition-count functional landed (section 14.7.7), and the witness class that entry names for the demand — structurally bounded resource-sharing net families — is instantiated by this model. The judgment stratum arrived in the same motion: the Rule Catalogue (chapter 15) now carries one plated-transfer rule per face, each concluding a formed  $S \models \varphi$  row — a surely-held invariant from one certificate citation per direction, and a roster firing-count ceiling from one gap-rowed certificate. What still separates this chapter’s rows from formed judgments is narrower than a missing former, and it is stated with the certificates (section 17.5.8).

The second family is *long-run*, and the claim class matters (section 2.1: these are the infinite-horizon-average rows of the taxonomy, and the class label travels with every result). Over the monolithic reading’s aggregate interface, with  $\text{wip}(t)$  the total work in progress and  $N(T)$  the completed-lot count, the specification atoms are:

- **stability**: there is a finite  $W$  with  $\limsup_{T \rightarrow \infty} \frac{1}{T} \int_0^T \text{wip}(t) dt \leq W$  — the line does not drown;
- **throughput**:  $\liminf_{T \rightarrow \infty} N(T)/T \geq \delta$  — the release rate is actually sustained;
- **cycle time**: mean flow time at most  $\varphi$  — which Little’s law,  $\bar{\varphi} = \bar{W}/\lambda$ , derives from the other two rather than asking anyone to certify it separately. Certify two, derive the third.

In the released vocabulary this family now splits down its middle, and the split is a fact about the language worth stating precisely. The stability atom *renders*: the long-run average is an accumulator of the specification vocabulary —  $\text{poAvg}$ , the Cesàro average of a state observable (section 14.5.6) — and the atom is its expectation cap,

$$\text{SReturnLE}(W, \text{poAvg}(\text{wip})),$$

the upper prevision of the averaged work in progress over every law the dispatched composite admits, with the residual freedoms (setup sequencing, allocation slack, tie-breaks) resolved adversarially — exactly the quantifier this family wants; the level faces (section 14.6.3) put threshold probes on the same functional, and the occupancy siblings render the same way: the long-run occupied fraction of a station is the average of an indicator observable, so “lithography is busy at least seven-eighths of the time, in the long run” is  $\text{SReturnGE}(7/8, \text{poAvg}(\cdot))$  over the busy-count indicator — the vocabulary’s own compositional spelling of occupation fractions. These renders form and build today (section 17.7 carries the live witness), and what stands behind a formed long-run claim is stated with the same care as everything else in this chapter: the average former’s certificate species — the gain/bias pair, a Poisson-equation drift row — is named by the rule catalogue and not yet claimed, so these are formed claims awaiting their battery, where the safety renders of the first family already sit on discharged certificates.

The throughput atom is the other half, and it now renders — as an envelope, which is the only honest shape for it.  $\liminf_{T \rightarrow \infty} N(T)/T$  as a bare long-run limit is deliberately not the vocabulary’s object — a limit claim carries zero finite-window content, so a consumer sized against it can be overwhelmed on any finite horizon — and the event-rate family’s primitive is instead the affine envelope from start (section 14.6.4). The throughput claim the list above records is the envelope’s lower face over the completion-transition roster, at the release rate  $\delta$  and a certified burst budget  $\sigma$ ,

$$\text{SRateGE}(\delta, \sigma, R_{\text{sink}}) :$$

along every admitted law, the expected completed-lot count dominates  $\delta t - \sigma$  at *every* horizon — which yields the displayed limit reading as a corollary ( $\underline{E}[N(T)]/T \geq \delta - \sigma/T$ ), never the other way around. What stands behind the formed claim is stated with the same care as the stability half’s: its certificate species — the lower-envelope drift rows, the Foster-Lyapunov shape whose potential’s forced descent pays out completions — is named by the rule catalogue and not yet claimed for this exhibit, so the throughput

render joins the long-run family's formed claims awaiting their battery. The argument the earlier edition recorded beside the vocabulary — census certified (section 17.5.4), drain rates bounded by the machine roster, a finite average-work-in-progress bound forcing  $wip(T)/T \rightarrow 0$ , the census pinning completion rate to release rate — is now the recipe for that certificate's potential rather than a measurement of an absence. And the cycle-time atom never wanted a former at all: Little's law derives it, as the list above already said.

Every claim of this second family is about a (system, policy) pair, never about the system alone. The undischarged claim — stable under *every* resolution of contention — is demonic, and for re-entrant lines it is typically *false* below capacity; the specification's refusal to let per-component stability compose across an undischarged boundary is correctness rather than caution. The first family, by contrast, needs no policy index at all — its claims are demonic by construction — and that is precisely why it can say nothing yet about sustained arrivals: a released lot *raises* every potential of section 17.5, and pricing arrivals is a different certificate species (the crossing budgets of the hybrid-process correspondence, section 12.16), deliberately not interchangeable with ranking rows. Today the arrivals story is the fluid lane's, the exactness story is the combinatorial lane's, and the frontier itself is the seam between them.

## 17.5 The combinatorial certificates

What has been certified about the discrete line, with no fluid scaling and no aggregate projection anywhere in the statement: the lot-flow core of the Mini-Fab — the exact Kempf process times, the machines at their true capacities (2, 2, 1), the full re-entrant route — as an SDCPN of the modelling catalogue's frame, a token-population System at its full combinatorial state space, carrying twelve plated certificates whose 150 footprint sequents are discharged in exact rational arithmetic, one row set covering *every* lot count, *every* scheduler, *every* run. The model is small enough to print whole, and this section does — the net on its own page in Petri notation (Figure 17.2), the classification tables beside it, and the certificate hypernets in plate notation (Figure 17.3); every constant below re-derives from the campaign committed beside the toolkit's semiconductor strategy, whose test battery replays the entire verification (chapter 19 for the producer stack; the strategy source and its battery ship in the toolkit repository).

### 17.5.1 The Mini-Fab as an SDCPN

The exhibit is declared in the SDCPN frame's own compositional reading — *places are Bags, arcs are patterns* (section 12.18) — and this subsection presents it the way the container carries it. Sixteen places, each a Bag of coloured tokens; as certificate subjects they are sixteen *plates* — symbolic token populations in the sense of section 10.4:

| places (as plates)                                  | count | tokens are                  | colour                          |
|-----------------------------------------------------|-------|-----------------------------|---------------------------------|
| $q_0$                                               | 1     | lots not yet released       | none                            |
| $q_1, \dots, q_6$                                   | 6     | lots waiting at step $k$    | none                            |
| $p_1, \dots, p_6$                                   | 6     | lots in process at step $k$ | remaining work $w \in [0, T_k]$ |
| $m_{\text{diff}}, m_{\text{impl}}, m_{\text{lith}}$ | 3     | idle machines               | none                            |

with  $T = (225, 30, 55, 50, 255, 10)$  the process times of section 17.1, read as unit-work quanta: a lot in process at step  $k$  carries the integer minutes of work it has left, in the declared colour box  $[0, T_k]$ . Nineteen Petri transitions, in five families, each declaring its clock species from the frame's own transition vocabulary:

| transition                    | count | firing                                                  | clock                          |
|-------------------------------|-------|---------------------------------------------------------|--------------------------------|
| release                       | 1     | $q_0 \rightarrow q_1$                                   | carved $[1, 1]$ , demonic seat |
| $\text{start}_k$              | 6     | $q_k + m_{\text{st}(k)} \rightarrow p_k$ at $w = T_k$   | carved $[1, 1]$ , demonic seat |
| $\text{tick}_k$               | 6     | $p_k$ at $w \geq 1 \rightarrow p_k$ at $w - 1$          | forced, dwell 1                |
| $\text{finish}_k$ ( $k < 6$ ) | 5     | $p_k$ at $w = 0 \rightarrow q_{k+1} + m_{\text{st}(k)}$ | carved $[1, 1]$ , demonic seat |
| ship                          | 1     | $p_6$ at $w = 0 \rightarrow m_{\text{lith}}$            | carved $[1, 1]$ , demonic seat |

The clock declarations are the SDCPN's own. Processing quanta ride the *forced* species at unit dwell (deterministic unit work); every scheduling choice — when to release, which waiting lot a free machine starts, when a finished lot moves on — rides a clock carved to the must-fire window  $[1, 1]$ , with the choice itself left to the demonic scheduler seat: timing owned by the clocks, choice by the seat. Nothing

else is pinned — no dispatch policy, no tie-break, no priority; both stochastic transition species stand available and unexercised, every firing law is Dirac, and no arc reads without consuming: the all-demonic, unit-dwell, Dirac corner of the frame, whose unfolding is the faithful ordering-and-counting embedding of an untimed net. Two derived time coordinates run through everything that follows, both read off these same clock rows: *counting time* — the unfolding’s step index, makespans in firings — carries every certificate statement from here to the carved clock, and *metric time* — the tick meter the carved windows define — re-prices the same rows on the wall clock (section 17.5.10). Whatever a certificate asserts below, it asserts against every scheduler at once.

Figure 17.2 draws the net whole, in Petri notation, initial marking and supervisor seat included; the tables that follow it print the classification: sixteen places as Bag populations, nineteen Petri transitions with every arc typed against the founding taxonomy of Everdij and Blom [71], the arc-type census with the pattern each element flows through, and the twelve certificates with their folds and transfer polarities. The rows of these tables are the rows of the emitted container — one table line per declared row, in the container’s own species vocabulary — so the isomorphism is checkable by diffing the page against the bytes, and the places where a declared row home is still a named successor are marked on the page rather than smoothed over. The pattern inventory the classification lands on is chapter 13’s: the destroy and create edges are the mode-switching machinery of section 13.3 in rendezvous with the transition’s timing seat (section 13.10), and the enabling-arc row — unexercised by the plant, exercised by the supervisor seat’s read-and-return wires (section 17.5.7) — is the per-tuple parameter-setting wire of section 13.1. The statics square behind the “mechanized” status entries is Problem 12.14, closed in the semantic-universe development.

Figure 17.2: The Mini-Fab exhibit of this section, in Petri notation: circles are places, rectangles Petri transitions; every arc runs place-to-transition or transition-to-place, bar at its source, head at its target — 16 places, 19 transitions, 49 arcs, the census of the classification tables of section 17.5.1. The initial marking is drawn:  $N = 7$  lots pending in  $q_0$  (the hexagonal cluster;  $N$  appears nowhere else in the model), and  $(2, 2, 1)$  idle machines. Colour coding: each in-process place  $p_k$  declares its colour type, tagged *colour*:  $T_k \rightarrow 0$  with  $T_k$  the step's work quantum; arcs *producing* into  $p_k$  (its start; its tick's return, paying one unit of  $w$  per firing) wear that type's hue, and every arc *consuming* from an in-process place wears the shared grey of the terminal colour 0 — the value each countdown drains to, and the guard at which finishes and shipment fire; the tag numerals wear the same coding. Machine take and give-back ride the rectilinear arcs to the pool places at the bottom — the two-steps-per-machine-group wiring (1,5 diffusion; 2,4 implantation; 3,6 lithography) is the re-entrancy. The dashed box at the foot is the open system's supervisor hole — the one seat the plant leaves open, labelled by the policy that fills it — drawn at the boundary the synthesized dispatch policy of section 17.5.11 exercises, one grammar with Figure 17.4, which draws that filler seated: two gate places  $g_1, g_5$ , whose read-and-return enabling arcs (a head at both ends) gate the two diffusion starts — the seat's act wires; two firing counters  $c_1, c_5$ , one token per  $\text{finish}_1/\text{finish}_5$  firing; and two pooled read-and-return taps on  $q_5$  and  $p_5$  — four observables; with the gates, the strict subset of the full-dispatch interface (section 17.5.12) that  $\pi^*$  needs. Boundary wires wear the gated step's hue; the boundary is drawn unfilled — gate tokens are exactly what a filler mints. The seat's *first* filler (section 17.5.7) sealed this same seat at a narrower interface — one weight- $N$  cumulative-arrival tap on  $q_6$ , a gate on  $\text{start}_6$ , and the armed plate's one-shot key, its conservation pair  $k + g = 1$  the certified Boolean gate discipline. The hole apparatus is the comb's, beyond the plant census above.

**Places** (species HPlate)

| #  | plate             | colour     | Bag carrier                      | init |
|----|-------------------|------------|----------------------------------|------|
| 0  | $q_0$             | —          | $\text{Bag}(1) \cong \mathbb{N}$ | $N$  |
| 1  | $q_1$             | —          | $\text{Bag}(1)$                  | 0    |
| 2  | $q_2$             | —          | $\text{Bag}(1)$                  | 0    |
| 3  | $q_3$             | —          | $\text{Bag}(1)$                  | 0    |
| 4  | $q_4$             | —          | $\text{Bag}(1)$                  | 0    |
| 5  | $q_5$             | —          | $\text{Bag}(1)$                  | 0    |
| 6  | $q_6$             | —          | $\text{Bag}(1)$                  | 0    |
| 7  | $p_1$             | $[0, 225]$ | $\text{Bag}([0, 225])$           | 0    |
| 8  | $p_2$             | $[0, 30]$  | $\text{Bag}([0, 30])$            | 0    |
| 9  | $p_3$             | $[0, 55]$  | $\text{Bag}([0, 55])$            | 0    |
| 10 | $p_4$             | $[0, 50]$  | $\text{Bag}([0, 50])$            | 0    |
| 11 | $p_5$             | $[0, 255]$ | $\text{Bag}([0, 255])$           | 0    |
| 12 | $p_6$             | $[0, 10]$  | $\text{Bag}([0, 10])$            | 0    |
| 13 | $m_{\text{diff}}$ | —          | $\text{Bag}(1)$                  | 2    |
| 14 | $m_{\text{impl}}$ | —          | $\text{Bag}(1)$                  | 2    |
| 15 | $m_{\text{lith}}$ | —          | $\text{Bag}(1)$                  | 1    |

**The arc-type census, classified**

| SDCPN element                 | #  | pattern instance                             |
|-------------------------------|----|----------------------------------------------|
| ordinary arc, input face      | 25 | Bag destroy edge (rendezvous)                |
| ordinary arc, output face     | 24 | Bag create edge <sup>†</sup> (spawn)         |
| enabledness count             | 19 | monotone scope rows                          |
| colour guard slab             | 12 | guard content on the edge                    |
| enabling arc                  | 0  | per-tuple parameter-setting                  |
| inhibitor arc                 | 0  | excluded by formation                        |
| delay (rate-raced) transition | 0  | race clock, finite majorant                  |
| forced (deterministic delay)  | 6  | forced clock, dwell 1                        |
| immediate transition          | 0  | race clock, infinite majorant                |
| demonic scheduling            | 13 | carved clock $[1, 1]$ ; choice stays demonic |
| firing measure                | 19 | Dirac reset legs                             |
| initial marking               | 1  | root init rows                               |

**Petri transitions** (species Transition: grain, clock, attachment)

| #  | transition          | consumes [guard slab]     | produces [colour law]  | clock           | reset rows              |
|----|---------------------|---------------------------|------------------------|-----------------|-------------------------|

| work-ceiling-max     | ceiling safety                  | max              | $v = R$                           | 19 safety (gap refused)                              |
| arrival-potential    | deadline ranking (reach $q_6$ ) | sum              | $v = D$                           | $16 \times \text{gap } 1 + 3 \text{ safety}$         |
| step6-budget         | post-arrival budget             | sum              | $v = F - D$                       | $3 \times \text{gap } 1 + 16 \text{ safety}$         |

**Places.** A place is a Bag of coloured tokens — remaining work  $w$  in its declared box for the in-process places, unit tokens (so: a counter) everywhere else. The machine plates are the resource-pool pattern in SDCPN dress: take and give are ordinary arcs, and the pool's conservation law is certified (the machine pairs above), not assumed.

**Transitions.** Every arc is an *ordinary* arc: each consumed entry is one input-face arc, each produced entry one output-face arc, every firing law Dirac — a deterministic colour polynomial in the consumed colours. There are no enabling arcs (every emitted selection row carries  $\text{read} = 0$ , a fact a reader can grep the container for) and no inhibitor arcs: enabledness everywhere is a monotone count-and-slab condition, so adding tokens never disables a step. Guard slabs are the footprint sequents' hypothesis slabs; every dwell is 1. <sup>†</sup>The six same-place ticks carry their reset as a declared scale row ( $\text{tr.scale}$ : image and reset polynomial in the container). The thirteen place-crossing transitions discharge their produced side directly in the exact-rational tier; the declared reset-row home arrives with the Bag reset-row presentation, staged for the next theory revision.

**The census.** Counts are arcs, transitions, or slabs. The zero rows read two ways: enabling arcs and both stochastic transition species are *available and unexercised* — this exhibit is the demonic-choice, carved-unit-dwell, Dirac corner of the frame (every clock carved to the window  $[1, 1]$ : timing owned by the clocks, choice by the seat), the discrete-time embedding of an untimed net, faithful for ordering and counting — while the inhibitor row is *unavailable by design*, warranted by the upward-closure theorem. Since every certificate quantifies over the demonic scheduler, its claims dominate every rate-raced refinement of the same scheduling freedom: the stochastic species, when they arrive, only resolve freedom the certificates have already priced. The founding taxonomy's conflict-resolution element is likewise priced rather than modelled: no priority or randomization rows exist, and every consequence holds by dominance over all of them at once.

**Certificates.**  $F$  is the remaining-firings dictionary ( $F_k = \sum_{j \geq k} (T_j + 2)$ ;  $v(q_0) = F_1 + 1 = 638$ ,  $v(q_k) = F_k$ ,  $v(p_k, w) = w + 1 + F_{k+1}$ , machines uncited) and  $R$  the remaining-work dictionary ( $R_k = \sum_{j \geq k} T_j$ ;  $v(q_0) = R_1 = 625$ ,  $v(q_k) = R_k$ ,  $v(p_k, w) = w + R_{k+1}$ ). Transfer polarity reads off the row profile: an all-gap sum certificate is a ranking (every firing pays, so runs are budgeted — 638 firings per lot, tight); a safety-rowed pair in both signs is a conserved place invariant ( $\#m_s + \#p_i + \#p_j = C_s$ ); the conjugated-power gap rows budget the ticks in  $\varphi$ -space; and the max fold carries safety only — a gap row on an idempotent fold is a formation error the vocabulary load-rejects, exercised by the mutant battery.

**Deadline.**  $D$  is the arrival dictionary:  $F$  with the step-6 remainder  $F_6 = T_6 + 2 = 12$  subtracted on every position before  $q_6$ , and 0 from  $q_6$  on —  $v_D$  vanishes exactly where a lot has entered  $q_6$ , so the fold's zero-set is the reach goal. The pointwise split  $D + (F - D) = F$  retells the ranking as a deadline argument: pre-arrival firings pay  $D$  (at most  $626N$  from  $N$  pending lots), post-arrival firings pay  $F - D$  (at most 12 per arrived lot), so along every maximal run every lot has entered  $q_6$  within  $T(N) = 638N - 12$  steps — counting time, the discrete-time unfolding's step index (the metric-time note below prices the same bound on the tick meter). Read as a Spec this is the deadline lower bound  $\bigwedge_{N \geq 1} [F \leq T(N)]$  (all  $N$  lots have entered  $q_6$ ) with demonic timing: in the Dirac corner every scheduler resolution is a point mass, the dictionaries quantify over the whole demonic seat, and the bound is tight — the schedule that defers the last finish<sub>5</sub> behind all other work attains it exactly (and typically-scheduled runs sit at it too: the step-6 tail is 12 firings against step 5's 255-tick pole). Three honesty lines the arithmetic enforces: the goal is *cumulative* arrival, never simultaneous occupancy ( $\#q_6 = N$  at once is demonically avoidable — start step 6 as lots arrive and  $q_6$  stays drained); the claim reads at the deadline wall (a record that stops existing is not late; the completion conjunct that upgrades the wall to full worst-case reach is the liveness face, priced separately); and the counting-time reading is primary but no longer alone — every clock in this encoding is carved to a finite must-fire window, and the metric-time note below prices the same bound with steps replaced by window widths. The judgment row binding this Spec to the container is the completion face's declared row home — not smoothed over: the deadline content shipped here is the two certificates' 38 footprint rows.

**Deadline, metric time.** With every clock carved to a positive finite must-fire window (dwell exactly one at these declarations), the counting deadline becomes a wall-clock statement: all  $N$  lots enter the finishing queue within  $638N - 12$  time units along every maximal schedule ( $626N$  under the latest-safe unlock) — probability 1, uniformly over the scheduler's remaining freedom. The certificate content is exactly the dictionary pair already presented; the transfer multiplies by the largest window ceiling (here 1), read off the model bytes by a must-fire census that refuses any idling member. Three clauses carry the reading, each at its stated tier: the dictionary rows are geolog-checked in-loop; the window-top law (a finite ceiling is a deadline) is the specification's declared clock semantics, its meter arithmetic owed at the proof tier; and maximality with deadlock-freedom-below-goal remain the same two argued clauses the counting statement already carries — the checkable species for the latter exists (the angelic-selection witness family) and awaits its active-region staging. The bound is firing-tight but not time-tight: simultaneously due windows fire in batches, and the round replay brackets the attained wall well below the certified one — structure, not slack in the rows.

**Open system and synthesis.** The plant opens into a comb: one supervisor seat whose declared interface reads the cumulative-arrival observable and drives the start<sub>6</sub> gate wire. A supervision-pattern filler closes it inside the model class — per gate, a gate place  $g$ , a one-shot key  $k$  (initial 1), and an unlock jump consuming  $k$ , reading  $q_6$  at weight  $N$  (returning what it reads) and minting  $g$ ; the gated Petri transition gains a read-and-return enabling arc, the census row the plant alone leaves at zero. Closed roster: 18 places, 20 Petri transitions, 14 certificates, 160 footprint rows — the plant's twelve certificates extend (the ranking pays the unlock's single firing through the key: total completing-run firings =  $638N + 1$ ), and the Boolean gate discipline is *certified*, not declared, by the conservation pair  $k + g = 1$ . Joint policy+certificate synthesis runs lexicographically: certified completion first (the gate that never opens ties the arrival optimum, then deadlocks with every lot in  $q_6$  shipping nothing — refused, starved plate named; so is the over-gated policy whose claimed horizon  $370N$  beats the optimum by starving arrival work out of its own constraint set), then minimize the certified horizon, where the least dictionary-certifiable  $T$  is an exact-rational linear program over dictionary space (gap rows on the admitted pre-goal roster, boxwise nonnegativity, goal pins, goal dominance) whose deterministic optimal vertex is the arrival dictionary  $D$  restricted to the closed roster. The winner is the latest-safe unlock (reopen exactly at the  $N$ th arrival): under it no pre-goal firing exists but the  $626N$  arrival-paying ones, so every schedule of the closed composite reaches all-arrivals at exactly step  $626N$  — against the open plant's  $638N - 12$ , a certified throughput-floor gain of  $12(N - 1)$  steps (+1.6% at  $N = 7$ ; +1.9% at the weekly  $N = 84$ : 52584 vs 53580). Honesty lines: the geolog-checked rows carry the *within*- $626N$  direction (gap rows in the loop); the *not-before* direction is the producer tier's exact-drop identities (each gap row's displacement equals its gap identically, both directions by Bernstein) plus the replay bracket, its in-loop row species a named absence; the  $626N$  floor over *all* fillers is plant arithmetic (626 lot-specific firings per arrival, one firing per composite step, policy firings only add); completion in every encoding is two-tier (ranking geolog-checked; enabledness below the ship goal argued); the seat's weight- $N$  observation read arc is the one arc-separation clause the flattened encoding cannot pass — carried as the staged observation stratum's named debt, never smoothed; and this armed-plate encoding has a native-read sibling (17 places, 20 Petri transitions, no key) whose completion carries one clause more — its unlock consumes nothing, so no ranking row can gap it, and unlock-fires-finitely-often rides as a stated convention — each variant citing its own roster and tier, neither borrowing the other's numbers.

Two structural findings the classification surfaces, both informative rather than embarrassing. First, the deliberate corner the clock table pins — all freedom demonic, all processing deterministic unit work, every firing law Dirac — is load-bearing for transport: the certificates are stated against that corner's adversary, which is the *largest* one, so every rate-raced or policy-refined elaboration of the same line — the stochastic species the frame holds ready, the failure and repair kernels of the fluid lane's fuller model — only resolves freedom these rows have already priced, and the classification doubles as a transport argument. Second, the machine plates exhibit the resource-pool pattern and the inhibitor exclusion in one stroke: mutual exclusion of a conserved unit needs only ordinary arcs plus the certified invariant (the machine-conservation pairs of section 17.5.4), and nowhere in a re-entrant line with true capacities does an absence test arise — the model never misses the excluded primitive, which is the exclusion argument of section 12.18 read off a working industrial subject.

### 17.5.2 One row per Petri transition

A certificate here is a plated certificate exactly as section 12.18 catalogues the species: a per-token *feature* — a polynomial in the representative token's colour block — on each cited plate; a commutative-monoid *fold* (sum, max, or the conjugated sums between them); and one *footprint sequent* per (certificate, Petri transition) pair, asserting that the firing's produced contribution is bounded by its consumed contribution — minus a pinned rational gap, on the rows that claim progress. Grammar equivariance is what makes the row finite: no expression names “the  $i$ -th token,” so the transition-level row is the family, at every marking, at every lot count. The twelve certificates below carry 150 footprint sequents in all — 19 each for the six whole-net certificates, 6 for each of the six machine-conservation certificates — and every sequent is a polynomial inequality of degree at most two over the declared colour boxes, discharged in the producer's exact tier by Bernstein-coefficient nonnegativity, in exact  $\mathbb{Q}$ , with no floating-point number representable in the pipeline. Coverage (every transition that may touch a cited plate carries a row), floor rows (gap-carrying folds bounded below), gap positivity, and scale-parameter conformance are checked in the same pass. The certificates themselves are finite drawn objects — plated feature cells, folds, four shapes carrying the whole roster — and Figure 17.3 draws them in plate notation.

### 17.5.3 The work potential, and the run-length budget

The flagship certificate is a shaped potential over the sum fold. Its feature dictionary is “remaining firings”: with  $F_k = \sum_{j \geq k} (T_j + 2)$  the firings a lot still owes from queue  $k$  onward (one start,  $T_j$  ticks, one finish per remaining step), assign

$$v(q_0) = F_1 + 1, \quad v(q_k) = F_k, \quad v(p_k, w) = w + 1 + F_{k+1}, \quad v(m) = 0.$$

Every one of the nineteen transitions carries a gap row with gap 1, and each is one line of arithmetic: a release moves a token from  $F_1 + 1$  to  $F_1$ ; a start consumes  $F_k = T_k + 2 + F_{k+1}$  and produces  $T_k + 1 + F_{k+1}$ ;

a tick pays one unit of  $w$ ; a finish consumes  $1 + F_{k+1}$  and produces  $F_{k+1}$ ; the final shipment consumes 1 and produces nothing the dictionary counts. Coverage is total, the floor is nonnegativity of the features, and the transfer consequence (section 12.18) is the specification's hard progress claim: **along every run from any marking  $m_0$ , the total number of transition firings is at most the fold  $V(m_0) = \sum v$  —** uniformly in the lot count and in the scheduler. At the Kempf constants the per-lot budget is

$$1 + \sum_{k=1}^6 (T_k + 2) = 1 + 625 + 12 = 638$$

firings, so  $N$  pending lots drain in at most  $638N$  firings — 53,592 at the nominal weekly release of 84 lots. And because this particular dictionary telescopes *exactly* — every transition drops the fold by exactly one — the bound is tight: every complete drain attains it, which the independent replay below measures at every tested lot count. This is the claim the fluid relaxation structurally cannot state (a continuous level supports no firing count), just as the arrivals-and-load claims of section 17.6 are the ones this certificate deliberately does not make.

The budget now has its render in the released vocabulary: for a run from marking  $m_0$ , the claim is the count ceiling  $\text{SReturnLE}(V(m_0), \text{retFireCount}(R))$  with  $R$  the full nineteen-transition roster (section 14.7.7), and the catalogue's ranking-face plated-transfer rule concludes exactly that judgment from one gap-rowed certificate — this one. What stands between this render and a formed row is recorded in section 17.5.8.

### 17.5.4 Conservation

Three certificate groups carry the bookkeeping claims, each over the sum fold with constant features.

*Lot census.* Feature 1 on every lot population (pending, queues, in-process; machines uncited): eighteen safety rows assert that no transition mints a lot, and the shipment transition carries a gap row — the census strictly drops exactly there. The transfer consequence: shipments along any run number at most the initial lot count. The dual lower bound is deliberately *not* certified, because it is false — lots genuinely leave at shipment — and the refusal is the honest content: this vocabulary cannot be talked into asserting conservation of a quantity the model does not conserve.

*Machine populations.* For each station, a pair of sum certificates — features  $+1$  and  $-1$  on the idle plate and the station's two in-process plates, safety rows on the six incident transitions — pins both directions of

$$\#m_s + \#p_i + \#p_j = C_s, \quad (C_{\text{diff}}, C_{\text{impl}}, C_{\text{lith}}) = (2, 2, 1) :$$

the classical place invariant, as certificate rows: a start takes an idle machine and opens an in-process slot, a finish does the reverse, a tick touches neither, and no other transition can touch the three plates at all — machines are neither minted nor lost, under any scheduler, at any lot count. In the specification vocabulary this pair renders as  $\text{PAlways}(\text{SAnd}(\text{SAtomLE}(C_s, \kappa_s), \text{SAtomGE}(C_s, \kappa_s)))$  for the station's population observable  $\kappa_s$  — a const-1 aggregate wire over the three cited plates, the same row species as the queue-length wires below; the judgment row that consumes the render is the catalogue's safety-face plated-transfer rule, whose conclusion is this conjunction under the sure cap  $\text{SProbGE}(1, \cdot)$  and whose premise shape — one certificate citation per direction — is this pair's own (section 17.4).

### 17.5.5 The bottleneck pair: two folds, one dictionary

The next two certificates share one feature dictionary — *remaining total work*: with  $R_k = \sum_{j \geq k} T_j$  (so  $R_1 = 625$ ), assign  $v(q_0) = R_1$ ,  $v(q_k) = R_k$ ,  $v(p_k, w) = w + R_{k+1}$  — and differ only in the fold, which is exactly the point.

*Congestion,  $\ell_2$ .* The conjugated-sum fold at  $p = 2$  (the scale-parametric family of section 12.18, strictly monotone at every finite  $p$ , interpolating from sum toward max). Read in  $\varphi$ -space, per that section's normative discipline — the rows constrain  $\sum_t v_t^2$ , and the checker never computes a root: every tick transition carries a gap row with  $\varphi$ -space gap 1 (from  $w \geq 1$ , the drop  $(w + R)^2 - (w - 1 + R)^2 = 2(w + R) - 1 \geq 1$ ), and every other transition carries a safety row, because the dictionary is arranged so that moves preserve remaining work exactly: a start converts  $R_k = T_k + R_{k+1}$  into  $w + R_{k+1}$  at  $w = T_k$ , a finish converts  $0 + R_{k+1}$  into  $R_{k+1}$ , and the shipment retires  $R_7 = 0$ . The even-power order-preservation

side condition is the nonnegativity of the feature range on the declared boxes — discharged, not assumed. Consequences: the  $\ell_2$  work-congestion measure never increases along any run, and processing quanta number at most the initial  $\varphi$ -mass  $\sum v(m_0)^2$ . Stated with the modulus honesty the modelling chapter demands: the  $\varphi$ -space budget is loose in aggregate units (at the weekly release the 52,500 ticks of the drain sit far below the initial  $\varphi$ -mass of  $84 \times 625^2 = 32,812,500$ ), which is exactly why the  $\varphi$ -space statement — not a root of it — is the certified one; the sharp tick count is the work potential's job, one certificate over.

In the released specification vocabulary the non-increase claim has a worked render today. The emitted aggregate wires include the  $\varphi$ -space work masses of the six in-process populations and the six queue lengths, so the congestion observable is the linear read-out

$$s_2 = \sum_k \text{l2work}_{p_k} + \sum_k R_k^2 \cdot \text{len}_{q_k} + R_1^2 \cdot \text{len}_{q_0},$$

and for a run from a marking with congestion value  $S_0$  the render is  $\text{PAlways}(\text{SAtomLE}(S_0, s_2))$  — formation per chapter 14, the atom's polynomial canonical over the wire coordinates.

*Ceiling, max.* The same dictionary under the max fold: every transition a safety row, no gap row anywhere — the maximum remaining total work over lots never increases. The asymmetry with the congestion certificate is enforced, not stylistic: section 12.18 establishes that idempotent folds are progress-incapable in every scale (an untouched dominating token absorbs any local drop), so a gap row on a max certificate is a *formation error*, and the vocabulary load-rejects it — the constructor refuses the row, and the mutant battery below exercises the refusal. Safety is what a max fold can carry, and safety is what this certificate claims.

(a) work-potential — hard progress (ranking); fold  $\Sigma$ ; dictionary  $F$

(one  $q_k$  and one  $p_k$  row per step,  $k = 1, \dots, 6$ ; all plate indices bound by the fold)  
 $F_k = \sum_{j \geq k} (T_j + 2)$ , the firings a lot still owes;  $v(m) = 0$ : machines uncited. One gap row per transition, gap 1 — 19 rows; along every run, from any marking  $m_0$ , total firings  $\leq V(m_0)$ , tight at 638 per lot.

(b) machine conservation — place invariants; fold  $\Sigma$ ;  $\pm$  twins

the  $-1$  twin certifies the reverse inequality, pinning  $\kappa_s = \#m_s + \#p_i + \#p_j = C_s$  under every scheduler, at every lot count;  $(s; i, j) \in \{(\text{diff}; 1, 5), (\text{impl}; 2, 4), (\text{lith}; 3, 6)\}$  with  $(C_{\text{diff}}, C_{\text{impl}}, C_{\text{lith}}) = (2, 2, 1)$  — 6 safety rows per certificate, 36 in all.

(c) the bottleneck pair — two folds, one dictionary  $R$

$R_k = \sum_{j \geq k} T_j$ , the work a lot still owes ( $R_1 = 625$ ); rows repeat per step as in (a). Congestion- $\ell_2$  (upper fold): obligations stated in  $\varphi$ -scale —  $\sum v^2$ , no root ever computed, verdicts transporting monotonely — 6  $\varphi$ -gap rows (the ticks) + 13 safety rows. Work-ceiling (lower fold): safety rows only (19); its gap row is *refused at load* — a gap row on an idempotent fold is a formation error, not a lint (section 12.18).

Figure 17.3: The exhibit's certificate hypernets, in plate notation. Each tinted enclosing box is a functorial box declared per node: the enclosed feature cell is applied once per token of the plate named at the box corner (its whiskered lift, section 10.4), and its wires carry the plate's symbolic extent, marked  $[q_k]$ ,  $[p_k]$ ; a fold node consumes the plated wires into one scalar. The drawn artefact is therefore a single finite object denoting a function of the whole variable-dimensional marking — the grammar has no expression for “the  $i$ -th token,” which is why one footprint row per (certificate, transition) pair covers every instance at every marking (section 17.5.2). The sum fold is contraction with the plate indices bound; constant features compile to the standard count wire, so (b) reads  $\kappa_s = \#m_s + \#p_i + \#p_j = C_s$ . Four shapes carry all twelve certificates of the classification tables (section 17.5.1): (a) the ranking; (b) the six machine invariants; (c) the two folds sharing the remaining-work dictionary  $R$ ; the lot census is (b)'s wiring with feature 1 on the nine lot populations ( $q_0, q_k, p_k$ ; machines uncited), 18 safety rows and a gap row exactly at shipment; and the deadline pair (section 17.5.6) is (a)'s wiring twice more, its dictionary split pointwise into  $D$  and  $F - D$  (16 gap + 3 safety, and 3 gap + 16 safety). Row total:  $19 + 19 + 36 + 19 + 19 + 38 = 150$  footprint rows, the tables' census.

### 17.5.6 The deadline pair: the flagship dictionary, split pointwise

The last two certificates price a deadline, and they cost no new dictionary: they split the work potential's  $F$  pointwise. Let  $D$  be the *arrival dictionary* —  $F$  with the step-6 remainder  $F_6 = T_6 + 2 = 12$  subtracted on every position before  $q_6$ , and 0 from  $q_6$  on — so  $v_D$  vanishes exactly where a lot has entered  $q_6$ : the fold's zero-set is the reach goal. *Arrival-potential* carries  $D$  over the sum fold: sixteen gap rows with gap 1, and safety rows on the three transitions at or past arrival, which pay nothing. *Step6-budget* carries the complement  $F - D$ : three gap rows on the post-arrival transitions, sixteen safety. The pointwise identity  $D + (F - D) = F$  retells the run-length budget as a deadline argument — pre-arrival firings pay  $D$  (at most  $626N$  from  $N$  pending lots), post-arrival firings pay  $F - D$  (at most 12 per arrived lot) — so along every maximal run, every lot has entered  $q_6$  within

$$T(N) = 638N - 12$$

steps: counting time, the discrete-time unfolding's step index. As a specification this is the deadline lower bound  $P_{\geq 1}[F_{\leq T(N)}]$  (all  $N$  lots have entered  $q_6$ ) with demonic timing — in the Dirac corner every scheduler resolution is a point mass, and the dictionaries quantify over the whole demonic seat. The bound is tight: the schedule that defers the last finish<sub>5</sub> behind all other work attains it exactly, and typically-scheduled runs sit at it too, the step-6 tail being 12 firings against step 5's 255-tick pole — the independent replay below witnesses both dynamically.

Three honesty lines the arithmetic enforces, stated rather than smoothed over. The goal is *cumulative* arrival, never simultaneous occupancy:  $\#q_6 = N$  at once is demonically avoidable (start step 6 as lots arrive and  $q_6$  stays drained), so no certificate of this pair claims it. The claim reads at the deadline wall — a record that stops existing is not late; the completion conjunct that upgrades the wall to full worst-case reach is the liveness face, priced separately. And the deadline above is stated in counting time; its metric-time twin rides the carved windows the clock rows already declare — a dwell floor with a finite must-fire ceiling — under which these same two dictionaries price the same bound with steps replaced by ticks (section 17.5.10). The judgment row binding the deadline specification to the container is the completion face's declared row home — a named successor; the deadline content shipped today is the pair's 38 footprint sequents.

### 17.5.7 The open system: the policy synthesized jointly with its certificate

The deadline pair prices the line against every dispatch at once, and that universality is also the bound's ceiling:  $638N - 12$  is what no scheduler can exceed, not what a good one achieves. The specification section already named the shape of the next claim family — everything long-run is about a (system, policy) pair, never the system alone (section 17.4) — and here the exact pathwise family acquires the same index, as *syntax*: the plant opens into a comb. Same sixteen places, same nineteen Petri transitions, plus one *hole* — the dashed box at the foot of Figure 17.2, a first-class term of the System grammar carrying nothing but a declared interface: read the cumulative-arrival observable, drive the start<sub>6</sub> gate wire. The hole is not a figure of speech; the emitted container carries the comb's own constructor rows, and the claim that exactly one hole occurs is decided in the production loop by an occurrence walk over those rows. What fills it is the supervision pattern of section 13.11, arriving exactly as that entry promised: the filler is an ordinary jump-only System owning a gate place, the gated transition carries a weight-1 read-no-consume enabling arc — the census row the plant alone leaves at zero — and the closed composite is again a coloured net of the same class. Supervision is composition inside the model class, so filling the hole is no semantic ceremony: it is one relation between three System terms, and the closed composite re-enters the same certificate machinery as the plant itself.

The synthesis is joint: policy and certificate are searched for together, the certificate machinery serving as the search instrument rather than a post-hoc audit. The objective is lexicographic, completion first. A candidate policy must first carry a certified completion claim — a ranking over the closed composite whose rows the checker re-derives — and only then competes on the certified arrival horizon, where the least dictionary-certifiable  $T$  is an exact-rational linear program over dictionary space: gap rows on the transitions the policy admits pre-goal, boxwise nonnegativity, zero pinned on the goal region, dominance everywhere a pending lot sits. Refutation is the improvement signal: exact replay of the closed composite under adversarial schedules either attains the certified horizon — closing the bracket pointwise — or returns a trajectory whose step ledger shows where the adversary spends its firings, which is precisely the gate the next candidate should own. On this model the search terminates at a theorem rather than a

timeout. The winner is the *latest-safe unlock* — hold  $\text{start}_6$  closed until the  $N$ th lot enters  $q_6$ , then open — and under it no pre-goal firing exists except the  $626N$  that pay the arrival dictionary, so every schedule of the closed composite reaches all-arrivals at exactly step  $626N$ . The linear program agrees from the other side: its deterministic optimal vertex is the arrival dictionary  $D$  of the deadline pair, restricted to the closed roster. Against the open plant's  $638N - 12$  the synthesized policy saves  $12(N - 1)$  steps — a certified throughput-floor gain of +1.6% at  $N = 7$  and +1.9% at the weekly  $N = 84$  (52584 against 53580) — and  $626N$  is the floor over *all* fillers: each arrival needs 626 lot-specific plant firings, firings interleave one per composite step, and policy firings only add, so no filler of this comb does better in counting time. The synthesized policy is not merely better; it is optimal, with both endpoints of the bracket certified objects.

The lexicographic order is not pedantry, and the mutant battery proves it the vivid way. Drop the completion clause and the “best” policy is the gate that never opens: it ties the arrival optimum — with the post-arrival work locked out, every firing pays the arrival dictionary, and all  $N$  lots reach  $q_6$  at exactly step  $626N$  — and then deadlocks with every lot in  $q_6$ , shipping nothing, a policy the deadline alone would score perfect. Its sharper sibling gates  $\text{start}_5$  instead and claims a horizon of  $370N$ , “beating” the true optimum by starving the arrival work out of its own constraint set: gap rows are demanded only on transitions the policy admits, so a policy that forbids the work escapes the rows that would price it. Both ride the battery with expectations committed in advance, and both are refused at the completion certificate, the starved queue named in the refusal. That is the completion-first discipline earning its place in the objective, and it is the synthesis story in miniature: the certificate engine does not merely bless the winner — it is what catches the degenerate candidates a deadline-only score would crown.

The campaign ships the closed composite in two encodings, and the difference between them is a certificate-tier fact, stated rather than smoothed. The *native-read* encoding adds one gate place and one unlock jump that reads  $q_6$  at weight  $N$  and returns what it reads — seventeen places, twenty Petri transitions, the roster the comb container carries — but its unlock consumes nothing, so no ranking row can gap it: a maximal run may spin the unlock forever instead of shipping, and “the unlock fires finitely often” rides as a stated convention, argued rather than checked, one clause more than the completion claim otherwise needs. The *armed-plate* encoding spends one more place to delete the clause: a one-shot key  $k$  with initial marking 1, consumed by the unlock — eighteen places, twenty Petri transitions — makes the extended ranking all-gap including the unlock (the completing run pays  $638N + 1$  firings, the key buying the single unlock) and turns the Boolean gate discipline from a declaration into a certified conservation pair  $k + g = 1$ , the machine-pair idiom aimed at the policy's own state. Each variant cites its own roster and its own tier; neither borrows the other's numbers. In both, the completion claim itself is two-tier — the ranking is geolog-checked; enabledness below the ship goal (some transition stays live while lots remain: in-process lots always tick or finish, machine conservation supplies an in-process lot whenever a station's idle plate is empty, queues are unbounded) is argued, the liveness face the deadline subsection already priced separately. The remaining honesty lines are the deadline pair's, inherited and extended. The geolog-checked rows carry the within- $626N$  direction; the not-before direction is the producer tier's exact-drop identities — each gap row's displacement equals its gap identically, both directions by Bernstein — together with the replay bracket, pointwise  $626N$  at every schedule tested, its in-loop row species a named absence (the lower-drift polarity the row vocabulary does not yet carry). The supervisor's weight- $N$  observation read arc fails exactly one clause of the supervision census — a policy arc reading a plant place; the packaged observation legs are the staged stratum that owns it — carried as a named debt in the container's own notes. And the filler-interface tie on a wired comb is refused producer-side, the substitution binding behind it argued until the checker-side evaluator lands. The two successors earlier editions of this chapter named here have both since landed against this comb, and the closing subsections of this section walk them: the metric rung — the carved clock, under which these same dictionaries price wall-clock deadlines and the dispatch seat is priced end to end (sections 17.5.10–17.5.12) — and the envelope arm, an uncertified dispatcher run inside a certified switching envelope whose downside the same family-level safety rows bound (section 17.5.13). That both were designed against this comb is the architectural point: the open system is one comb, and everything after it is fillers.

### 17.5.8 What checks these rows — today, and next

The trust story is staged, and each stage is named rather than blurred.

- **Discharged today, re-runnable from the public tree:** all 150 footprint sequents, coverage, floors,

gap positivity, and scale-parameter conformance, in the producer's exact tier (Bernstein-coefficient nonnegativity over the declared colour boxes, exact  $\mathbb{Q}$ ). The campaign — model, dictionaries, rows — is committed beside the toolkit's semiconductor strategy, and its test battery replays the whole verification, so these numbers are a cargo test away rather than a transcript's word.

- **Discharged today, in the production loop:** emitted certificate containers are sealed deterministically (double emission is byte-identical), and the engine-side theory provider discharges the canonicity claims — one per distinct feature polynomial, forty at this model — while refusing containers that claim nothing (a vacuous accept is structurally unavailable, and the battery below includes the probe). Since the evaluator family reached the coloured tier, the same in-loop walk also discharges the plated side-condition claims the container now carries: footprint on the thirty-six tick rows — the flagship's six, whose colour-typed feature dictionaries are read and decided from the container's own bytes, the lot count's six, the machine conservations' twelve, and the deadline pair's twelve — flow on all twelve certificates, and the five floor claims the sign analysis reaches, with zero refusals and zero failures on the real emission; a standalone checker binary consuming the same sealed bytes reports identical tallies.
- **Landed at a named fragment, refused loudly beyond it:** the theory demands its own side-condition families for every plated certificate — footprint, coverage, floor, flow, and parameter conformance — and the engine-side evaluator family that discharges them in-loop is now decided at the coloured place/transition fragment: same-place colour dictionaries, sum folds, displacement settled where it is constant or of single-signed even shape over the colour space, exact  $\mathbb{Q}$ . What still lies beyond is named per row rather than blurred: coverage and the thirteen place-crossing transitions' footprint rows await the produced-side reset-row presentation; the congestion ticks, the flagship's floor, and the conjugated power's parameter conformance await the declared colour-box rows (the Bernstein-over-box core that will decide them is written and exercised against exactly these shapes); the machine lower bounds' floors await a coupling route for negative features; and the max fold is an idempotent kind, outside the polynomial walk by design. A claim placed on any of these is refused with the unrealized case named — the battery below exercises two such refusals — so their discharge remains the exact tier's, replayed independently below, and the demand rows travel with the container either way: nothing is silently waived.
- **The warrant, and the judgment:** the run-length consequence rests on the transfer argument of section 12.18 — elementary telescoping, each dropped hypothesis refuted there by a finite countermodel. The judgment stratum has landed since this campaign first ran: the catalogue's plated-transfer pair concludes formed  $S \models \varphi$  rows for the safety and ranking faces, with the verification content normative in the evaluators' walks (section 17.4). The catalogue states what remains open, loudly: no Lean statement binds either rule node yet, so the formal lemma pack is still the named successor. The gap is not hidden in the artefact: the certificate carries rows and demands, and states its consequence as a consequence.
- **Jurisdiction, measured:** extraction toward the certified-binary checker reports this family's containers as carrying no content in that checker's fragment — correctly, and by design: plated rows are certificate-stratum vocabulary outside the fragment the machine-code soundness theorem binds, and their discharge route is the evaluator family and the lemma pack above, not the certified binary. The measured refusal is the correct answer, and it is the division of labour the stack's consumers were built to make explicit: one set of bytes, checkers that fail differently, none asked to vouch beyond its fragment.
- **The reproduction spine:** this campaign's committed home in the experiments repository, with a make target per number, arrives with the spine's uniform regeneration — the motion that has already reached the fluid lane next door (section 17.6) — and the chapter's numbers move in lock-step with it.

### 17.5.9 The mutant battery and the independent replay

Twelve deliberately corrupted campaigns, expectations committed before any run, each aimed at a specific gate and each in fact refused there: a broken gap (a tick that returns its token unchanged — the exact tier's footprint discharge fails); a gap row on the max fold (refused at construction — the formation error

above, exercised); a dropped footprint row (the coverage gate); a nonpositive gap (the gap-positivity gate); a conjugated power at  $p = 0$  (the parameter floor); a non-canonical feature polynomial (killed in the production loop by the engine provider's canonicity check — a real in-loop kill, not a producer-side courtesy); a container claiming nothing (refused in-loop as a vacuous accept); now that the claims themselves ride in-loop, three aimed at the coloured walk: a broken gap in the emitted bytes (its footprint claim *fails* in the loop — lying bytes under a live claim); a footprint claim placed on a row the walk cannot yet decide (refused, the missing colour-domain stratum named); and a floor claim on a negative-feature certificate (refused, the unbuilt coupling route named); and, with the deadline pair landed, two aimed at its rows: a corrupted arrival dictionary (the exact tier's footprint discharge fails at the mutated transition, the locus named), and a deadline gap inflated in the sealed bytes under a live claim (the in-loop footprint claim fails on the corrupted row — the checker refuses a lying deadline).

Beside the battery, an independent replay closes the artefact pair: an exact-rational drain simulation — written against the model tables, not the certificate code, with its expectations committed before the run — executes seeded demonic schedules at lot counts 1, 2, 5, and 84, and confirms: every drain terminates cleanly with all lots shipped and machine populations restored to (2, 2, 1); total firings equal  $638N$  *exactly* at every lot count and every schedule tested (the budget is tight, as the telescoping predicts); every firing satisfies every touched certificate row in its reading scale; the place invariants pin; the congestion fold is monotone with ticks inside the  $\varphi$ -space budget; every seeded schedule meets the deadline, with the arrival fold reaching zero exactly at the  $N$ th arrival; the adversarial schedule that defers the last finish<sub>5</sub> attains  $638N - 12$  *exactly* at every tested lot count (the deadline bound is tight dynamically, as the split predicts); and the broken-gap mutant violates its row at the *first* mutated firing — the dynamic kill agreeing with the static refusal. The replay rides the toolkit's workshop today and lands in the reproduction spine with the vendoring motion above.

### 17.5.10 The carved clock: the same rows in real time

The clock rows of section 17.5.1 support two readings, and everything so far in this section has used the first: *counting time* — makespans measured in firings, the discrete-time unfolding's step index — where total work is scheduler-invariant ( $638N$  firings, always: the work potential's telescoping) and *when* the work happens is the only nontrivial question. This subsection and the four that follow read the same declared clocks the other way — *metric time*, the tick meter — and push the open-seat story to its natural end: what the wall clock rewards, exactly how much, a policy that attains the optimum, a machine-checked sense in which “optimal” is the decision-theoretically right word, a deliberately untrusted policy run inside a certified envelope, and one certificate that spans lot counts from 7 to  $10^7$ . The subject is unchanged — the lot-flow core, with the model boundary stated at this section's end inherited whole.

The metric-time semantics is already in the declarations: every transition's clock is carved to the window  $[1, 1]$ , so each row dwells exactly one tick and fires at most once per tick — the per-row meter law; simultaneous instances resolve through the demonic scheduler seat, so the only freedom left is genuinely dispatch freedom. Both closed-composite encodings of section 17.5.7 reseal under this reading with row tallies identical to the counting-time containers — the certificates themselves never change.

Two transfers move the counting-time results onto the wall clock. First, upper bounds transfer by a *no-idle* argument: before the goal, a tick with an empty due set — no enabled transition instance whose one-tick dwell has elapsed — would freeze the state forever, so along every goal-reaching schedule each tick fires at least one row, and ticks-to-all-arrivals is bounded by pre-goal firings: at most  $626N$  ticks under the synthesized gate and  $638N - 12$  open, carried by the *same* geolog-checked rows plus two named glue clauses, argued — the meter/no-idle lemma and enabledness below the goal. Second, there is a wall-clock *floor* over all dispatch policies of any kind, supervisory or never-idle:

$$\text{ticks to all arrivals} \geq 255N + 371 \quad (21,791 \text{ at the weekly } N = 84),$$

because step 5's service tick is one row — at most one firing per tick, 255 firings per lot — behind an uncompressible 370-event first-lot pipeline fill, plus the final transfer into the arrival queue. The bound is Z3-verified below  $N = 8$ , and its machines-deleted variant is refused too (checked at  $N \leq 2$ ): machine capacity is not the binding constraint; the clock law and per-lot precedence are. (Tight at  $N = 1$ : the singleton trajectory takes exactly 626 ticks.)

Measured against that floor at  $N = 84$ , the dispatch levers separate cleanly. The synthesized arrival gate, whose counting-time value is certified (section 17.5.7), moves wall-clock arrivals 0.0%: greedy dispatch reaches all-arrivals in 22,019 ticks with the gate on or off — the gate’s value was always the certified worst-case floor, a guarantee over every schedule, not a typical-case speedup. Pull order is a  $1.83\times$  lever (an adversarial pull priority needs 40,406 ticks, +83.5%); and greedy itself sits 228 ticks above the floor. Real-time value lives almost entirely in the dispatch seat — which is why the optimum is a policy story, next, and why the seat then widens (section 17.5.12).

### 17.5.11 Optimal throughput, exactly

The exact optimum is known in closed form at small  $N$  and attained at every tested  $N$ :

$$T_{\text{opt}}(N) = 255N + 371 + d(N), \quad d = 0 \ (N \leq 2), \quad 2 \ (N = 3), \quad 4 \ (N \geq 4),$$

certified two-sided for  $N \leq 7$  by exhaustive Z3 search — satisfiability with an independently re-validated witness schedule at  $T_{\text{opt}}$ , unsatisfiability at  $T_{\text{opt}} - 1$  — and the +4 plateau is attained by an explicit supervisor family  $\pi^*$ , drawn seated in its interface as Figure 17.4 (hold the first few diffusion starts on one machine with two-tick handovers, then alternate pre-positioned; run the step-1 services back to back) at every tested lot count ( $N \leq 8, 12, 30, 84$ ): 21,795 ticks at the weekly count, within 4 ticks (0.018%) of the machine-free floor above, and *exactly* optimal in per-lot throughput at all  $N$  — 255 ticks per lot, matched from both sides. The attainment side is *container replay*, geolog-checked:  $\pi^*$ ’s explicit firing table replays against the sealed exhibit bytes to arrival at exactly 21,795, under the meter law, every hold accounted. The floor side now meets it exactly. The machine-free floor is *not* attainable for  $N \geq 3$  (Z3 refuses it outright), and the reason is mechanized — Lean-checked: a five-case machine-contiguity analysis of the first four diffusion entrants, showing any schedule faster than  $255N + 375$  leaves the third or fourth lot’s service without a contiguous machine window — and it *collapsed* under mechanization: the tick-meter forces two pigeonhole machine handovers, three of the five cases dying inside the first forcing. That lifts the certified floor to  $255N + 375$  for  $N \geq 4$  ( $255N + 373$  at  $N \geq 3$ ; the mechanized anchors match the Z3 optima exactly at  $N \leq 7$ , and the  $N = 3$  value  $d = 2$  is Z3-certified two-sided), which the replayed attainment meets exactly — the four-tick daylight between floor and attainment is closed,  $N$ -uniformly, and the mechanization explains why the plateau is +4: it is the double diffusion handover  $\pi^*$  saturates. In the same pass the counter/meter bookkeeping behind the machine-free floor landed as geolog-checked rows — this container family’s first checker-side clock-law rows.

Two consequences deserve their own sentences. *Deliberate idling is necessary for optimality*: for  $N \geq 3$  the best never-idle (work-conserving) policy needs  $255N + 455$  ticks — at the weekly count, 80 ticks behind  $\pi^*$ , with its never-idle law verified at every pre-goal tick of the container replay — and a measured greedy baseline runs 224 ticks behind; gating the *last* step moves arrivals 0.0%, while holding the *diffusion starts* recovers the full gap. The necessity is also mechanical: replaying  $\pi^*$  with holds disallowed is *refused* by the engine at its first delayed diffusion start. Where the supervisor holds is what the last 80 ticks are made of. And *the decision-theoretic reading is discharged, not gestured at*: with deterministic closed dynamics the belief state is a point mass, and imprecise-decision-theoretic selection at the widest-uncertainty locus provably collapses to makespan minimization — the reduction Lean-checked against the mechanized imprecise-decision-theory development, with a concrete refutation cell showing the collapse fails without determinism. “The synthesized policy is decision-theoretically correct” therefore means optimal throughput — the optimality receipts above discharge it, each at its stated grade, and the seat-regret face of the specification vocabulary (section 14.6.5) is where the language states exactly this shape: the regret of a filler against its own seat, here 0 at every tested lot count — two-sided by Z3 at  $N \leq 7$ , the Lean-checked floor met exactly beyond.

Figure 17.4 closes the subsection by drawing  $\pi^*$  as what it is: a filler for the supervisor seat, the Petri page’s dashed box grown to nearly the whole page, one enormous Petri transition inside — the policy’s firing kernel, its interior a plate-notation hypernet over the seat’s four observables. The page and its caption carry the policy’s entire content: no code, no lookup table, no appeal to the replay — two threshold cells and two piecewise-constant schedule decoders, readable in one look.

the plant of the Petri page, elided to the diffusion re-entrancy (steps 1 and 5 share the machine pool); everything ungated is omitted

Figure 17.4: The synthesized optimal policy  $\pi^*$ , drawn as what it is: a filler for the supervisor seat. The dashed seat of Figure 17.2 is here nearly the whole page, and the plant survives only as the gated neighbourhood along the top — the diffusion re-entrancy, where  $\text{start}_1$  and  $\text{start}_5$  compete for the same two machines. Straddling the boundary, the seat's declared interface: the two pooled reads, the two firing counters, and the two gate places — a strict subset of the fifteen-observable, four-act full-dispatch interface of section 17.5.12, and the only wires  $\pi^*$  needs. Inside sits one enormous Petri transition: the policy's firing kernel, applied once per tick, reading the four observables and rewriting the two gates. Its interior is a hypernet in the plate notation of Figure 17.3: the pooled observables are two plated folds ( $\ell = \sum 1$  over  $[q_5]$ , the queue length;  $u = \sum w$  over  $[p_5]$ , the in-service residual — pre-positioning keeps at most the incumbent in  $p_5$ , so the sum reads its residual), the counters decode the schedule phase through the two dashed cells ( $\theta, \varphi$  — defined symbols, not primitive generators: piecewise-constant functions of the counters, closed forms in the box), and two threshold cells (region-membership) emit the gate bits. Holding  $\text{start}_5$  until  $u \leq \theta$  pre-positions each diffusion slot; holding  $\text{start}_1$  at the quota keeps a diffusion machine free for step 5 — deliberate idling, the one capability the never-idle class lacks. What this filler attains, each claim at its tier (section 17.5.11): all arrivals in  $255N + 371 + d(N)$  ticks,  $d = 0, 0, 2$ , then  $4$  — 21,795 at the weekly  $N = 84$ , on the certified all-policy floor exactly (attainment geolog-checked by container replay, every hold accounted; the floor itself Lean-checked); exactly optimal for  $N \leq 7$  by exhaustive Z3 search, two-sided. The best never-idle policy needs  $255N + 455$  — these two gates are worth the last 80 ticks, and replaying  $\pi^*$  with holds disallowed is refused at its first delayed diffusion start. Under deterministic closed dynamics, imprecise-decision-theoretic selection provably collapses to makespan minimization (Lean-checked) — so this page is also the decision-theoretic optimum. Initial marking drawn:  $g_1$  open ( $c_1 = 0 < \varphi$ ),  $g_5$  shut ( $\ell = 0$ ).

### 17.5.12 Widening the seat: full dispatch as a filler

The supervisor seat of section 17.5.7 reads one observable and drives one gate wire. That narrowness was an encoding shim, not a formalism limit: an interface always was a pair of port lists, and the same comb construction re-seals the same single seat with a *full-dispatch* interface — fifteen observables (six queue lengths, three machine-idle flags, six in-process work counts) and four act ports (three per-station pull decisions plus token selection) — around the unchanged plant. The closed net is the plant net, so the exhibit's twelve-certificate family binds every filler *a fortiori*, geolog-checked: the sealed full-dispatch container re-verifies with the full row roster, and the certificate never mentions the policy.

Two findings from exercising it. Token selection is a *second* dispatch freedom that determinism requires: a pull priority alone does not close the system; fixing both yields one trajectory per policy, verified by replaying residual-order permutations to identical traces. And across the 16-policy deterministic grid (8 pull priorities  $\times$  2 selection rules,  $N \in \{1, 7, 84\}$ ; Table 17.1), only the diffusion-station pull preference binds the outcome — the implantation and lithography columns of the table never move a number — while token selection swings roughly 7,000 ticks and *crosses* with pull preference; the best cell lands on  $255N + 455$  exactly at  $N \in \{7, 84\}$  — the work-conserving optimum of the previous subsection, consistent with the separation proved there, since grid policies never deliberately idle. Threshold-style gate supervisors provably cannot express per-station pull preference — argued: a gate place maintained by fixed-weight fused arcs is an affine functional of the marking, read through upward-closed thresholds, and a pull preference's acceptance region is a union no affine threshold carves. Dispatch is a genuine seat species, not sugar over gates — enablement carving and seat selection are different composition operations.

### 17.5.13 An untrusted policy in a certified envelope

The envelope certificates — safety, floors, the deadline — never read the policy: they quantify over every filler of the seat, which is why the policy may be *anything*, including a black box nobody should trust. (The per-policy rows of Table 17.1 do read the policy — but only as a replayed *trace*, re-checked row by row against the sealed container, so even the performance claims ask for no trust in the box, only in the replay.) A third closure of the same seat demonstrates exactly that: the open comb filled by an uncertified lookahead heuristic (a stand-in for a learned or LLM dispatcher) composed with a certified switching envelope — a decision-budget bench with a certified recovery region. In replay: the heuristic ran free, was never benched, completed, and attained the envelope's arrival bound  $638N - 11$  *exactly* at the tested  $N = 84$  — one tick above the open plant's  $638N - 12$ , the closed composite's own unlock firing — so the bound is witnessed tight, not merely sound; a deliberate idler hit the budget boundary and was benched, with recovery at exactly 1,009 firings; a rogue policy was benched after eight named in-loop refusals with the plant untouched; and disabling the bench stalls the line — the switch is load-bearing, not decorative. After all runs the sealed container re-verified *byte-identical*: the certificate is carried entirely by the envelope, geolog-checked, and no behaviour of the filler — competent, idle, or hostile — can touch it.

### 17.5.14 One certificate, every lot count

The deadline certificates of this section are stated once and instantiated at any lot count  $N$ : the sealed container's row obligations (footprint, flow, floor, canonicity) never mention  $N$  — they quantify over *all* markings — and  $N$  enters only as three integers in the container's own data (the initial lot count, the unlock guard's threshold multiplicity, and hence the instantiated horizon, which the reader recovers from the marking row by one dot product with the arrival dictionary). Table 17.2 instantiates, reseals, and re-verifies the pair of exhibits at lot counts spanning six orders of magnitude. The certificate's byte size moves only with the decimal width of those integers (six bytes across the whole sweep); the checker's wall time is flat at  $\sim 2$  ms; and the objects the claims quantify over grow combinatorially — at  $N = 10^6$  the model has at least  $2 \times 10^{38}$  reachable markings and at least  $10^{2 \times 10^7}$  distinct maximal schedules, and the checker never visits any of them.

**What is  $N$ -parametric and what is not — the honest split.** The *certificate* and the *checker* are  $N$ -parametric in the strong sense: the same 36 footprint rows (this container's share of the exhibit family's 150 footprint sequents), the same dictionaries, the same claim roster discharge at every  $N$  (identical tally vectors across the sweep), and at the landed weekly count the resealed container reproduces the landed

| dispatch policy                                                        |       |                   |       | ticks per arrival |       |                |       | certified optimality (%) |        |            |        |          |

| $q_5$                                                                  | $q_4$ | $q_3$             |       |                   |       | least-advanced | 626.0 | 384.7                    | 343.2  | —          | 75.61  | —        |
| $q_5$                                                                  | $q_4$ | $q_6$             |       |                   |       | least-advanced | 626.0 | 384.7                    | 343.2  | —          | 75.61  | —        |
| $q_1$                                                                  | $q_2$ | $q_3$             |       |                   |       | least-advanced | 626.0 | 445.0                    | 397.1  | —          | 65.34  | —        |
| $q_1$                                                                  | $q_2$ | $q_6$             |       |                   |       | least-advanced | 626.0 | 445.0                    | 397.1  | —          | 65.34  | —        |
| $q_1$                                                                  | $q_4$ | $q_3$             |       |                   |       | least-advanced | 626.0 | 445.0                    | 397.1  | —          | 65.34  | —        |
| $q_1$                                                                  | $q_4$ | $q_6$             |       |                   |       | least-advanced | 626.0 | 445.0                    | 397.1  | —          | 65.34  | —        |
| $q_1$                                                                  | $q_2$ | $q_3$             |       |                   |       | most-advanced  | 626.0 | 448.6                    | 477.4  | —          | 54.35  | —        |
| $q_1$                                                                  | $q_2$ | $q_6$             |       |                   |       | most-advanced  | 626.0 | 448.6                    | 477.4  | —          | 54.35  | —        |
| $q_1$                                                                  | $q_4$ | $q_3$             |       |                   |       | most-advanced  | 626.0 | 448.6                    | 477.4  | —          | 54.35  | —        |
| $q_1$                                                                  | $q_4$ | $q_6$             |       |                   |       | most-advanced  | 626.0 | 448.6                    | 477.4  | —          | 54.35  | —        |
| certified floor, all policies (255N+375, $N \geq 4$ , met by $\pi^*$ ) |       |                   |       |                   |       |                | 626.0 | 308.6                    | 259.5  | 255.000375 | 100    | 100      |

Table 17.1: All seventeen policies of these subsections, benchmark-style (the synthesized policy itself is drawn as the seated filler in Figure 17.4): the sixteen never-idle full-dispatch cells (three binary pull preferences  $\times$  token selection; deterministic replay, verified by residual-order permutations) and the synthesized  $\pi^*$ , which is not a row of the grid because it deliberately idles — the one capability the never-idle class lacks, worth exactly the last 80 ticks. Read the parameter columns: only the diffusion column ever moves a number; the implantation and lithography preferences are provably irrelevant at this roster. Token selection crosses with pull preference (most-advanced wins under  $q_5$ , loses under  $q_1$ ). Units: ticks per arrival ( $T/N$ , the throughput cost of one lot; the asymptotic ideal is 255); at  $N = 1$  every policy ties the floor at 626.0 (the floor is  $255N + 371$  there, and tight: no contention). “Certified optimality” is the certified floor divided by the policy’s attained ticks: the fraction of certifiably-unbeatable performance the policy *provably* delivers.  $\pi^*$ ’s column reads 100.00 at the weekly count — earned, not rounded: the four-tick daylight between the machine-free floor and the attainment closed when the machine-contiguity tree was Lean-checked (section 17.5.11), and the certified floor now meets the replayed attainment at  $255N + 375$  exactly. The closure is  $N$ -uniform, so the  $N = 10^6$  column reads 100.00 as well. The sixteen never-idle cells are deterministic replays and do not extend to  $10^6$  (simulation is the bottleneck there by design, Table 17.2); only rows whose attainment has a certified closed form carry those columns — which is itself the point. The single-supervisor lanes of section 17.5.10 show the same pull-order lever at the same magnitude (40,406 ticks under an adversarial greedy pull there).

exhibit exactly. Re-instantiation at a new  $N$  does re-run the *producer*: it reveals the container (0.002 s at  $N = 84$ , 106 s at  $N = 10^7$  — the producer’s in-memory form expands the weight- $N$  guard unarily, a linear-cost implementation artifact of the untrusted side that never touches the sealed bytes or the checker), and re-derives the exact-rational producer receipts (the  $=$ -direction’s drop identities; 0.002 s at  $N = 84$ , 9.8 s at  $N = 10^6$ ). Dynamic attainment witnesses (replays arriving at exactly  $626N$ ) were re-run through  $N = 10^4$ , i.e. 6,260,000-step runs; beyond that the replay grinder’s quadratic cost makes simulation the bottleneck — which is the point of certifying.

**Claim grades at every  $N$ .** The within- $T^*$  direction rides geolog-checked rows at every  $N$  (the row obligations are  $N$ -free; the horizon instantiates from the container’s marking row). The not-before direction and exact attainment remain producer-tier receipts, and completion keeps its graded split (ranking geolog-checked, enabledness glue argued), exactly as stated with the certificates above — instantiation at large  $N$  upgrades nothing and degrades nothing.

**The contrast columns, derived not simulated.** Both bounds are conservative combinatorics on the net. *Markings*: lots distribute over pending, the six queues, and shipped; with machines idle every such distribution is reachable (advance one lot at a time) and distinct, giving  $\binom{N+7}{7}$  reachable markings before counting any in-process or machine state. *Schedules*: two lots processing concurrently on distinct stations

| $N$    | $T^* = 626N$  | $638N - 12$   | cert. (B) | check (ms) | markings $\geq$      | schedules $\geq$       |

Table 17.2: The synthesized-policy deadline certificate instantiated at lot count  $N$ . Columns: the certified all-arrivals horizon under the synthesized gate ( $T^* = 626N$  steps, exact on every completing run); the no-policy worst case ( $638N - 12$ ); the sealed container’s size in bytes (supervised exhibit; the no-policy container runs 2,963–2,966 B over the same sweep); the checker’s wall time (median of 7 re-discharges of the sealed bytes by the production engine’s in-loop evaluator walk, single core of an NVIDIA GB10 (Grace, aarch64) under concurrent load; all samples across all rows fell in 1.7–2.0 ms); a reachable-marking lower bound; and a lower bound on distinct maximal schedules the claims quantify over. Intermediate lot counts  $10^4$  and  $10^5$  were measured identically (containers 3,107 and 3,109 B; medians 1.9 ms).

(one in step 1, one in step 2) admit  $\binom{259}{32} \approx 10^{40.9}$  interleavings of their firing chains, all distinct as transition words; scheduling  $\lfloor N/2 \rfloor$  such pairs in blocks gives  $\binom{259}{32}^{\lfloor N/2 \rfloor}$  distinct maximal runs. Every one of them is covered by the same  $\sim 3$  kB of certificate.

**Reproduction.** Every certificate in these subsections is available as a sealed container, together with a one-command reproduction kit that rebuilds the independent checker at a pinned revision, re-verifies each container from its bytes alone — with per-relation claim counts as a load-bearing gate and committed integrity mutants that must refuse — and re-runs the producer-tier mutant batteries. The dispatch grids, the Z3 optima (each satisfiability/unsatisfiability pair re-derives in one command), and the  $N$ -scaling sweep ship the same way (section 2.9).

**The model boundary, honestly.** Everything in this section — counting time and carved clock alike — certifies the lot-flow core, and each exclusion is a named refinement rather than fine print: diffusion’s batching-of-three and its mix rules, product types and test-lot dedication, the declared buffer capacities, the transporter, the operators and technician, the maintenance calendars and failures, and the timed weekly release schedule. The certificates are arranged to survive the refinements that only restrict runs — a conservation or safety row over all schedulers holds *a fortiori* over fewer — while refinements that add Petri transitions re-run the same discharge over the extended roster; and arrivals-as-births are, as stated in section 17.4, a different certificate species with its own budget vocabulary, not a missing row here. Nothing in this section claims throughput under sustained release; that claim lives, for now, one section over — about the relaxation.

## 17.6 The fluid certificates: the comparison lane

The second certificate family predates the first and certifies a different object: the *fluid model* of the Mini-Fab’s deterministic core skeleton, under two named dispatch policies, with every residual freedom resolved adversarially. It is retained in full — as the comparison lane — because it answers exactly the question the combinatorial family does not yet price: sustained arrivals, at stated loads, policy by policy. The contrast, stated once: a fluid certificate asserts stability of the *relaxation* — continuous levels, aggregate drain rates, indexed by a dispatch policy — at releases within a tenth of a lot per week of capacity; a combinatorial certificate (section 17.5) asserts exact statements about the *discrete system* — every run, every lot count, scheduler-uniform — with no continuum limit anywhere. Neither family subsumes the other today, and the seam between them is measured rather than smoothed over: the granularity conversion still open on the fluid side is named at this section’s end, and the arrivals species still open on the combinatorial side is named at section 17.5’s. All numbers in this section re-derive from the committed artefacts in the experiments repository — the certificates and their mutant battery under `semicon/out/minifab`, replayed by the independent checker through the repository’s semiconductor make target — and are displayed

under the conventions of section 2.2. The campaign summary lives in section 2.7; this section walks the same artefact at reading depth.

### 17.6.1 The fluid model, with its decisions priced

Fluid scaling replaces lot counts by continuous levels  $q \in \mathbb{R}_{\geq 0}^6$ , one per route step, drained at the stations' machine-occupancy rates. From the tables of section 17.1, with handling folded into occupancy (the machine is held during load and unload, per-batch at diffusion):

| step | station (machines) | occupied min/lot | per-machine rate (lots/min) |
|------|--------------------|------------------|-----------------------------|
| 1    | diffusion (2)      | 285/3 = 95       | 1/95                        |
| 2    | implantation (2)   | 60               | 1/60                        |
| 3    | lithography (1)    | 75               | 1/75                        |
| 4    | implantation (2)   | 80               | 1/80                        |
| 5    | diffusion (2)      | 315/3 = 105      | 1/105                       |
| 6    | lithography (1)    | 30               | 1/30                        |

The declared-model ledger is explicit, in the spirit of the cookbook's declared-prior pattern (chapter 19): operators are folded into machine occupancy rather than modelled as a contended resource (that layer is the pool seam of section 17.3); products share a single class per step (the mix enters only through total release; dedication and batch-mix rules are granularity effects that vanish in fluid scaling); batching becomes a rate (3 lots per 285 or 315 machine-minutes); arrivals are deterministic at exact rate  $\lambda$ ; and failures and maintenance are excluded from the core skeleton — their sound entry point is capacity intervals from availability moments, named successor work, not fine print smuggled into these certificates. Setups get two sound variants: a core variant with no setups (matching the capacity arithmetic), and a setup-adversarial variant in which every lithography job may pay up to the full worst-case 12-minute setup, encoded as service-rate intervals  $\mu_3 \in [1/87, 1/75]$  and  $\mu_6 \in [1/42, 1/30]$  resolved adversarially at every instant — so the certificate quantifies over every setup sequencing with no monotonicity assumption anywhere (queueing networks are not monotone in service rates; intervals sidestep the issue rather than arguing it). Worst-case-inline setups put lithography's per-lot occupancy at 129 minutes, an adversarial ceiling of  $10080/129 \approx 78.1$  lots/week.

The two named policies are the classical static priorities for re-entrant lines: *last-buffer-first-served* (LBFS — later steps preempt earlier ones for their station's capacity: step 5 over step 1, 4 over 2, 6 over 3) and *first-buffer-first-served* (FBFS, the reverse). These are the disciplines the Kumar–Seidman destabilization literature is about, which is what gives “stable at  $\rho$ ” its falsifiable content. FIFO is not directly certified — its fluid content is class-level dispatch, per section 17.2 — but the setup-adversarial rows soundly cover FIFO's setup burden for *any* within-class order at loads up to 78 lots/week. Everything the policy does not pin — allocation slack on empty classes, idling below the top positive priority, rate realization inside the declared intervals — is inside the adversary.

### 17.6.2 The certified statement and its checker

Each certificate exhibits a linear Lyapunov function  $V(q) = \langle w, q \rangle$  with  $w \in \mathbb{Q}_{>0}^6$  and an exact rational  $\varepsilon > 0$  such that along *every* admissible fluid trajectory under the named policy,  $\frac{d}{dt}V(q(t)) \leq -\varepsilon$  for almost every  $t$  with  $q(t) \neq 0$ . Consequently any work-in-progress profile  $q_0$  drains to the empty line within  $V(q_0)/\varepsilon$  minutes, stays drained, and the line sustains its release — the stability and throughput atoms of section 17.4 at once, with a quantitative drain rate as the bonus.

The checker (`fluidcheck`, a small Rust program) trusts nothing about how the certificate was found. It rebuilds every polytope itself from the declared network data — routes, rates, capacities, policy — and replays one exact-rational Farkas dual per *sign mode*: for each of the  $2^6 - 1 = 63$  nonempty patterns of which queues are positive, the admissible drift vectors form a polytope, and the certificate's dual for that mode is a nonnegative combination of the polytope's constraints witnessing  $\langle w, \dot{q} \rangle \leq -\varepsilon$  over all of it. Soundness rests on weak linear-programming duality and one measure-theory lemma — the next subsection — and on nothing else; in particular, no solver, no floating-point arithmetic, and no completeness claim about the producer participates in the trust story. Each certificate carries 819 obligations and re-verifies in 1.5–3.0 milliseconds on one CPU core. The producer that found the certificates (floating-point proposal,

exact-rational certification, self-replay before emission) took about 0.2 seconds per certificate — and is, per the conventions, freely sloppy: being wrong costs retries, never soundness.

The bespoke container is, since this campaign first shipped, no longer the only committed form. Ten of the twelve certificates below are re-emitted as sealed geolog-commit containers on the unified certificate schema, in two committed lanes — one against the reproduction vocabulary, one pinned to the baked theory pair — each lane carrying its own mutant battery and re-verified, sign mode by sign mode, through the engine’s exact-rational ground seam; section 2.9 records the transition’s terms, and the two tree-cover certificates await their species’ re-emission. The original containers remain the record of the campaign that produced this section’s numbers, and the checker above still replays them — a committed lane never dies.

### 17.6.3 The boundary-equality lemma, the hinge

One semantic decision carries the entire result. What does the fluid model say about an *empty* buffer? The lazy encoding says only  $\dot{q}_k \geq 0$  when  $q_k = 0$  (levels stay nonnegative). The right encoding says more:

**Lemma 17.1** (boundary equality). *Let  $q_k : [0, \infty) \rightarrow \mathbb{R}_{\geq 0}$  be absolutely continuous. Then at almost every  $t$  with  $q_k(t) = 0$ , the derivative exists and  $\dot{q}_k(t) = 0$ .*

(At almost every point of the level set  $\{q_k = 0\}$  — discard the null set where  $q_k$  is not differentiable — the point is a Lebesgue density point of the set, hence an accumulation point of other zeros, and a derivative along a sequence of zeros is zero.)

The measured difference between the two encodings is not a refinement at the margin. Under the inequality-only semantics, the adversary may pour phantom flow into empty buffers whose station idles, and *no linear Lyapunov function exists at any tested load* — the certificate family is empty. Under the equality, linear certificates exist to within a tenth of a lot per week of fluid capacity. The equality also makes many sign modes vacuous: at the flagship configuration, 41 of the 63 mode polytopes are empty (a pattern like “only  $q_5$  positive” forces full diffusion output through an empty downstream line that lithography cannot pass). Vacuity needs no case split and no emptiness branch in the checker: an infeasible polytope has an unbounded dual, so the same Farkas row shape that certifies a drift bound on a nonempty mode certifies any bound on an empty one. The checker has one code path, on purpose.

### 17.6.4 The ladder

Twelve certificates and two deliberate failures, all replayed by the checker from the committed artefacts:

| certificate                     | policy | variant   | lots/week     | $\rho_{\text{lith}}$ | $\epsilon$ (V-units/min)                  |
|---------------------------------|--------|-----------|---------------|----------------------|-------------------------------------------|
| lbfs_core_84wk                  | LBFS   | core      | 84            | 0.875                | 1/3600                                    |
| lbfs_core_90wk                  | LBFS   | core      | 90            | 0.938                | 1/7200                                    |

(\*) setup-adversarial utilization is measured against worst-case-inline lithography occupancy, 129 min/lot. (a) exact value 6923209477/24747380706600; the display is rounded in the claim-weakening direction. (t) emitted as fully-refined sign-split *tree covers* — the certificate format’s refinement species, adjudicated by the checker’s tree walk rather than the mode-mask walk — with the weight search and all cell duals solved as one sparse linear program.

V-units are normalized so  $\sum_k w_k = 1$ :  $V$  is a weighted lot count. At the flagship configuration the optimizer’s own weights came out as  $w = (7, 7, 7, 3.5, 3.5, 2)/30$  — remaining-lithography-work flavoured,

found by the linear program, not designed. A worked reading: a ten-lot backlog at step 1, at the nominal 84 lots/week release, has  $V = 7/3$  and is certified to clear within 8400 minutes — under six days — against every adversarial resolution of the residual freedoms.

The table carries three findings. First, the certified load meets capacity: certificates exist at 95.9 of 96 lots/week (99.90% of fluid capacity) and at 78 of the 78.1-lot adversarial ceiling (99.8%); producer-side bisection brackets the last certifiable release within  $6 \times 10^{-5}$  lots/week of the fluid capacity (the one-lot gap in the original release grid was grid granularity, not lost capacity); and the probes at 96 and 79 fail *because the load is genuinely at or over capacity* — so the demonic generosity (everything unpinned handed to the adversary) is measurably free here, costing less than a tenth of a lot per week of certified capacity. Second, the exact drain rates separate the policies: FBFS edges LBFS near capacity (1/38880 versus 1/43200 at 95 lots/week; 1/287280 versus 1/299040 at the adversarial 78) — both stable everywhere tested, consistent with the classical fluid-limit picture for re-entrant lines, and the kind of exact policy comparison the claim class was chosen to produce. Third, the certificates and the reference simulation triangulate: certified setup-adversarial stability up to 78 lots/week  $<$  simulated FIFO stability at 84  $<$  the simulated deterministic-core ceiling at 87  $<$  certified zero-setup capacity at 96. The gap between 78 and 87 is the certificate’s conservatism against worst-case setups (24 minutes of setup per lot charged by the adversary, against 9.4 measured for FIFO in simulation) — and closing most of it is a policy question (run-length policies amortize setups), not a checker limitation.

The mutant battery, per the standing convention (section 2.2): seven deliberately corrupted certificates — inflated  $\epsilon$ , zeroed weight vector, negated dual, broken policy identity, dropped mode, swapped modes, over-capacity release — each designed to be refused at a specific check, and each in fact refused.

**What this section does not claim.** These are claims about the declared fluid model of the deterministic core, not about the discrete line — whose own certificates are section 17.5’s, and are of a deliberately different species: exact run-length budgets and invariants, not rate stability under arrivals. Of the granularity work that converts a fluid drain rate into discrete-line guarantees for the count chain, the Little’s-law (exact-moments) half has since been discharged: a discrete-lot certificate species replays lot-level cycles deterministically, certifying rate stability at the fluid capacity itself — a statement no fluid certificate can make — together with exact steady work-in-progress and cycle-time moments from declared initial families, with its own designed-locus mutant battery. The Foster–Lyapunov half — universal coverage over all mixed work-in-progress states — remains open, as does the sound entry of failures and maintenance via availability intervals, and the personnel, transport, and batching-granularity layers live on the composite seams of section 17.3 until those patterns carry certificates of their own. Nothing here claims either policy is *optimal* — only that its stability region is certified, to within a tenth of a lot per week of the model’s capacity, by an artefact a reader can re-refuse and re-accept on their own machine in milliseconds.

## 17.7 The construction in TypeScript

One orientation before the listing: the construction below is the fluid lane’s (section 17.6) — the model it assembles is the aggregate reading, and the certificates it drives are the release-grid drain certificates of that section’s ladder. The combinatorial campaign of section 17.5 is produced today on the toolkit’s Rust strategy surface; its TypeScript twin awaits the production-strategy surface on the toolkit’s TypeScript side (the specification surface’s revision has since landed, and this section’s listings ride it), and this section will grow that second listing when the surface lands, rather than simulate one now.

This section was staged until the toolkit’s TypeScript construction surface shipped, with its acceptance test fixed in advance: a single executable listing entering the ground tables of section 17.2 as rows, declaring the mechanisms as manifests, assembling the composite, forming specification content against the aggregate interface, handing the obligation set to the session workspace of chapter 8, and — driven over the same release grid — producing certificates the independent checker accepts at every load certified in section 17.6 and none at the two probe loads that correctly failed there. The surface shipped; the listing runs; the test passed, on the terms recorded at the end of this section. The complete file is committed as `qtsl/book/listings/minifab.ts` (with its emission seam `fluidseam.ts` beside it), against the `@maitria/mtk` and `@maitria/mtk-session` packages of section 7.6 and section 8.10; the excerpts below are verbatim slices of it, and the transcripts are the run’s own output.

The ground tables enter exactly as section 17.2 declared them — stations, route steps, release generators, the lithography setup rules, the implantation failure brackets — as data the rest of the file compiles from, so they are not reprinted here. The mechanisms are: each station at the aggregate stratum (per-visit queue levels, a busy-machine count, and the one device the platform renders every duration with — a timer drifting at rate one), with the declared buffer and machine capacities carried as domain constraints:

```
function station(st: number): system.System {
  const visits = ROUTE_STEP.filter((r) => r.st === st); // two per station
  const n = visits.length;
  const width = n + 2; // queues, busy, timer
  return system.buildSystem({
    name: STATION[st].name,
    state: [
      ...visits.map((r, v) => ({ id: v, name: `q${r.idx}`, sort: "Nat" })),
      { id: n, name: "busy", sort: "Nat" },
      { id: n + 1, name: "tau" },
    ],
    interface: {
      inputs: visits.map((r, v) => ({ id: v, name: `arrive${r.idx}` })),
      outputs: visits.map((r, v) => ({ id: v, name: `complete${r.idx}` })),
    },
    modes: [
      {
        id: 0,
        name: "serving",
        domain: [
          ...visits.map((_, v) => ({ poly: mono(width, v), op: "ge", rhs: 0 })),
          ...visits.map((_, v) => ({
            poly: mono(width, v),
            op: "le",
            rhs: STATION[st].bufcap,
          })),
          { poly: mono(width, n), op: "ge", rhs: 0 },
          { poly: mono(width, n), op: "le", rhs: STATION[st].machines },
        ],
      },
    ],
    drift: [{ mode: 0, var: n + 1, poly: constant(width, "1") }], // tau' = 1
    init: { kind: "point", coords: Array.from({ length: width }, () => 0) },
  });
}
```

The release mechanism is three timers (the thesis's signal-generator idiom is the timer-mechanism idiom, as section 17.2 observed), the sink counts finished lots and pools their flow times, and each conserved unit — operators, technician, transporter — is a unit-capacity pool mechanism whose conservation range is likewise a domain constraint. None of these manifests matches a catalogued profile, and none needs to: the free constructor never refuses, and the preflight's `noKnownProfile` notes in the transcript below are classification, not complaint — a mechanism whose populated family set matches no preset is a first-class citizen of chapter 12.

The composite wires the re-entrant lot flow, completion wire into arrival wire along the route:

```
const fab = system.composite({
  name: "minifab",
  components: [release, diff, impl, lith, sink, ...pools],
  wiring: [
    flow([0, 0], [1, 0]), // release      -> diffusion    (step 1)
    flow([1, 0], [2, 0]), // diffusion    -> implantation (step 2)
    flow([2, 0], [3, 0]), // implantation -> lithography  (step 3)
    flow([3, 0], [2, 1]), // lithography -> implantation (step 4)
    flow([2, 1], [1, 1]), // implantation -> diffusion    (step 5)
    flow([1, 1], [3, 1]), // diffusion    -> lithography  (step 6)
    flow([3, 1], [4, 0]), // lithography -> finished lots
  ]
});
```

```
1,
});
```

One boundary deserves stating here, where the code makes it concrete rather than abstract: the directed lot-flow seams of section 17.3 are constructible today, as the wiring rows above; the *pool-membership* and *event-fusion* seams are the event-port stratum, whose fusion primitive now carries a producer surface (typed fusion rows over the stations' population edges; section 13.10) while the pool-membership packaging is still design-tense, which is why the pools stand here as constructed mechanisms whose seize and release bindings await the packaged rows. And the dispatch freedom enters precisely where section 17.6 put it: as the policy index of each certificate, carried below by the release-grid driver, not as a row on this composite.

The specification content formable in the released vocabulary is the certificates' own quantitative consequence — the worked reading of section 17.6, as a typed record over the six-level aggregate interface:

```
const drainSpec = spec.build({
  name: "minifab drain: LBFS core 84/wk, ten lots at step 1",
  forall: [spec.probGe(1, spec.deadline(8400, spec.polyLe(0, wip)))] ,
  iface: {
    invars: [],
    outvars: ROUTE_STEP.map((r) => ({ name: `q${r.idx}`, shape: [] })),
  },
});
```

with *wip* the sum of the six coordinate polynomials. The long-run family of section 17.4 enters the same file at its formable half: the stability atom, through the average former. For the fluid skeleton under this policy at this release the honest cap is zero — the line drains and stays drained, so the transient washes out of the time average:

```
const longRunStable = spec.build({
  name: "minifab long-run: LBFS core 84/wk, average wip",
  forall: [spec.returnLe(0, spec.poAvg(spec.oPoly(wip)))] ,
  iface: {
    invars: [],
    outvars: ROUTE_STEP.map((r) => ({ name: `q${r.idx}`, shape: [] })),
  },
});
```

The record preflights, builds, encodes, and round-trips on the released surface (the receipt below carries the run); its resting state is the one section 17.4 assigns it: a formed claim whose certificate species is named and not yet claimed, so in the workspace's books the obligation would stand open — which is where a claim without its battery belongs. The throughput atom stays out of this listing for a narrower reason than it once had: its former is staged in the theory (section 14.6.4), but the producer surface quoted here does not construct it yet, and this listing does not simulate constructions the toolkit does not have.

The producer core is the Cookbook's propose-then-dispose discipline (chapter 19) on the checker's own vocabulary: the listing rebuilds the same constraint rows the checker rebuilds, asks one floating-point robust linear program for candidate weights (purely a proposal), then certifies one exact dual per sign mode and replays every obligation in exact arithmetic before emitting a byte. The equality rows are where two of this chapter's decisions become five lines of algebra — the boundary-equality lemma (Lemma 17.1) as flow conservation on each empty buffer, and the policy's entire fluid content as saturation above each nonempty priority level:

```
function eqRows(net: Net, mask: number): Row[] {
  const k = net.k;
  const rows: Row[] = [];
  for (let i = 0; i < k; i++) {
    if (!(mask >> i) & 1) {
      // buffer i empty: inflow = outflow (a.e. zero derivative)
      const r = zeros(2 * k);
      r[i] = Q.from(-1);
      net.route.forEach((succ, j) => {
        if (succ === i + 1) r[j] = r[j].add(Q.from(1));
      });
    }
  }
}
```

```

        rows.push({ r, rhs: net.arrivals[i].neg() });
    }
}
net.prio.forEach((order, s) => {
  for (let pos = 0; pos < order.length; pos++) {
    if ((mask >> (order[pos] - 1)) & 1) {
      // a nonempty buffer at priority: everything at or above it
      // saturates the station
      const r = zeros(2 * k);
      for (const j of order.slice(0, pos + 1)) r[k + j - 1] = 0.from(1);
      rows.push({ r, rhs: net.caps[s] });
    }
  }
});
return rows;
}

```

Finally the obligation set, handed to the session workspace: one obligation per grid point, probes included, under a statement kind whose single move runs the producer, emits through the canonical encoder, and lets the checker adjudicate. The kind's failure mode is part of its design: at an infeasible load it returns *inconclusive* — “the load is at or over the variant's capacity; absence of a certificate is not a refutation” — because no certificate is not a disproof, and the workspace's books are only as good as the outcomes recorded in them.

```

const GRID: [string, string, number][] = [
  ["LBFS", "core", 84],
  ["LBFS", "core", 90],
  ["LBFS", "core", 94],
  ["LBFS", "core", 95],
  ["LBFS", "core", 96], // probe: fluid capacity
  ["FBFS", "core", 84],
  ["FBFS", "core", 95],
  ["LBFS", "setup-adversarial", 72],
  ["LBFS", "setup-adversarial", 76],
  ["LBFS", "setup-adversarial", 78],
  ["LBFS", "setup-adversarial", 79], // probe: over the adversarial ceiling
  ["FBFS", "setup-adversarial", 78],
];

const ws = new Workspace([fluidStable]);
for (const [policy, variant, lotsPerWeek] of GRID) {
  const ob = ws.pose({ kind: "minifab.fluidStable", policy, variant, lotsPerWeek });
  const r = ws.apply(ob.id, "farkas");
  const w = r.attempt.witness as { eps?: string; checker?: string } | undefined;
  console.log(
    `${ob.id} ${ws.describe(ob.id)}\n -> ${r.attempt.outcome}` +
    (w ? `eps=${w.eps} (${w.checker})` : ` (${r.attempt.note})`),
  );
}

```

The run, whole — construction, specification, and the twelve obligations — takes under four seconds:

```

$ npx tsx minifab.ts
composite: minifab (composite), schema maitria.system.manifest.v0;
  9 preflight notes, kinds: noKnownProfile
spec: built ("minifab drain: LBFS core 84/wk, ten lots at step 1")
ob1 fluid skeleton drains under LBFS (core) at 84 lots/week
  -> discharged eps=1/3600 (ACCEPT modes=63 obligations=819 eps=1/3600)
ob2 fluid skeleton drains under LBFS (core) at 90 lots/week
  -> discharged eps=1/7200 (ACCEPT modes=63 obligations=819 eps=1/7200)
ob3 fluid skeleton drains under LBFS (core) at 94 lots/week
  -> discharged eps=1/21600 (ACCEPT modes=63 obligations=819 eps=1/21600)
ob4 fluid skeleton drains under LBFS (core) at 95 lots/week

```

```

-> discharged eps=1/43200 (ACCEPT modes=63 obligations=819 eps=1/43200)
ob5 fluid skeleton drains under LBFS (core) at 96 lots/week
-> inconclusive (the load is at or over the variant's capacity;
  absence of a certificate is not a refutation)
ob6 fluid skeleton drains under FBFS (core) at 84 lots/week
-> discharged eps=6923209477/24747380706600 (ACCEPT modes=63
  obligations=819 eps=6923209477/24747380706600)
ob7 fluid skeleton drains under FBFS (core) at 95 lots/week
-> discharged eps=1/38880 (ACCEPT modes=63 obligations=819 eps=1/38880)
ob8 fluid skeleton drains under LBFS (setup-adversarial) at 72 lots/week
-> discharged eps=11/74760 (ACCEPT modes=63 obligations=819 eps=11/74760)
ob9 fluid skeleton drains under LBFS (setup-adversarial) at 76 lots/week
-> discharged eps=23/448560 (ACCEPT modes=63 obligations=819 eps=23/448560)
ob10 fluid skeleton drains under LBFS (setup-adversarial) at 78 lots/week
-> discharged eps=1/299040 (ACCEPT modes=63 obligations=819 eps=1/299040)
ob11 fluid skeleton drains under LBFS (setup-adversarial) at 79 lots/week
-> inconclusive (the load is at or over the variant's capacity;
  absence of a certificate is not a refutation)
ob12 fluid skeleton drains under FBFS (setup-adversarial) at 78 lots/week
-> discharged eps=1/287280 (ACCEPT modes=63 obligations=819 eps=1/287280)

12 obligations: 10 discharged, 2 open (96wk, 79wk)
flagship V weights: (7/30, 7/30, 7/30, 7/60, 7/60, 1/15)

```

And the acceptance test's other half, against the standalone checker binary over the emitted files:

```

$ for f in out/*.cbor; do fluidcheck $f > /dev/null && pass=$((pass+1)); done
$ echo "standalone fluidcheck: $pass/10 ACCEPT"
standalone fluidcheck: 10/10 ACCEPT

```

Read the transcript against the ladder of section 17.6. The acceptance criterion was checker-acceptance, deliberately — a reimplemented producer may find different valid certificates — and what happened is a report, not a promise: this producer landed the *same* certificates. Every drain rate matches the table's, down to the FBFS exact value whose display there is rounded; both probes fail for the right reason; and the weight vector  $w = (7, 7, 7, 3.5, 3.5, 2)/30$  — which that section reported as found by the linear program, not designed — has now been found twice, by two implementations proposing over the same polytopes. The independence boundary is drawn where it always is in this book: the *producer* above is a fresh implementation on the TypeScript surface, while the emission seam links the checker crate itself, so that the bytes written and the bytes judged pass through one canonical encoder (at this preview the seam is a thin binding around the checker crate the reproduction spine imports; its migration is tracked in section 2.9) — and the standalone binary replays every certificate from the bytes alone, trusting nothing about how they were made.

# Implementation Pearls

---

DRAFT

This chapter is written in the tradition of Bentley’s *Programming Pearls* [16]: short, self-contained engineering essays, one per design decision that earned its place in the producer stack. The genre has a discipline of its own — a pearl is not advice; it is a technique with the measurement that decided it — and this chapter keeps to it. Each essay states the problem, the technique, and the receipt: numbers from committed artefacts, reproducible from the public repositories where the artefact has migrated, and identified as workshop-record measurements where it has not yet (per the preview note at the front of this volume). The common thread is that *certified-producer engineering* — code whose every output faces an unforgiving checker — quietly inverts several classic engineering trade-offs, and each pearl records one such inversion. Where the agents’ cookbook (chapter 19) states the moves of a good untrusted producer, this chapter states the decisions that hold up the machinery those moves run on.

## 18.1 The Certifying Tier Is a GPU Workload Too

**The problem.** The producer stack’s central split — a fast float tier proposes, an exact tier certifies (chapter 19, *Sloppy Proposer, Exact Disposer*) — is usually read as a hardware split: floats on the device, exact rationals on the host. The economics that force floats out of the inner search loop seem, by the same logic, to force exactness off the device. In the workshop prototype that seeded the toolkit’s kernels, one per-leaf basis-change GEMV at a realistic shape cost  $715\ \mu\text{s}$  in exact- $\mathbb{Q}$  arithmetic on the CPU, against  $4.65\ \mu\text{s}$  in directed  $\text{f64}$  on the same CPU and 191 ns on the device — three and a half orders of magnitude between the exact path and the device path. Leave exactness host-side and serial, and the moment search becomes device-fast, certificate assembly becomes the pipeline’s ceiling.

**The technique.** Put the exact tier on the device as an *integer* workload. The certifying kernels in `crates/mtk` represent a batch of rational tables as sign-magnitude integer numerators in base- $2^{64}$  limb planes over *one* positive shared denominator per cell (the schoolbook common-denominator move, industrialized), so that every transform is an integer recurrence with an explicit denominator-bookkeeping rule: no division, no gcd, no floating point anywhere in the certifying path. Reduction to canonical form happens host-side at the boundary. Fixed-capacity limb arithmetic is sound only if capacity exhaustion is *detected*, never wrapped, so every product writes into scratch of compile-time capacity with stated headroom lemmas, every store back is fit-checked, and the carry-out flag is captured and treated as overflow anyway — the lemma and the flag would both have to fail. On overflow the kernel poisons the cell: outputs zeroed, routing flag set, the cell’s work abandoned. A poisoned cell’s outputs are never read; the promotion ladder re-derives it from its *inputs* at the next tier — a wider device width, up to sixteen limbs, then unbounded host integers. Being wrong about a width costs a retry one rung up, never a wrong table. The kernels themselves ship as embedded CUDA source, compiled at runtime for whatever device is present, which makes the development loop one cargo run on any machine; an ahead-of-time path can join later behind the same module seam (and when it does, the pipeline-of-record law of section 18.3 applies to it).

**The receipt.** The exact-tier selftest runs eleven cases spanning the census shapes, fused transform chains, a  $\sim 130$ -digit-coefficient regime, and engineered overflow-boundary fixtures, demanding bit-exact equality against the host big-integer reference for every reduced table entry, every verdict, and every first-violation address — with the promotion ladder’s rungs each demonstrably exercised. Replaying a committed certificate from its bytes reproduces its certified threshold — a 55-digit reduced rational — bit-for-bit across three substrates: Python fractions, Rust `num-bigint`, and CUDA `u64` limb planes.

The full soundness burden, including what “bit-exact” means here and the residual risks, is stated in `crates/mtk/BERNX-SOUNDNESS.md` in the `maitria-coalition/mtk` repository.

## 18.2 Round Outward — to the Verifier’s Resolution

**The problem.** The base law of float participation in a certified system is directed rounding: on any verdict-relevant path, every operation rounds toward the safe side — toward  $-\infty$  for lower bounds, toward  $+\infty$  for upper bounds — so enclosures stay enclosures. The law is necessary, and it is not sufficient. A certifier campaign in the workshop lineage banked the counterexample: its checker decides transcendental sign questions by bisection on a dyadic lattice, deepening to a resolution of  $2^{-256}$ , and a producer emission relying on a  $10^{-70}$  relative guard alone can land a correctly-rounded margin *below one lattice unit*. Every rounding outward, every claim true in  $\mathbb{R}$  — and undecidable at any depth the checker will ever spend: a correct refusal of a true claim, forever.

**The technique.** Treat the emission grid as part of the interface. The producer quantizes every emitted bound outward onto a dyadic grid coarse enough that each claimed margin clears the verifier’s decision lattice by whole grid steps — in the campaign above, one full  $2^{-96}$  step outward keeps every margin decidable at bisection depth 16–64. The doctrine gains a clause: *exactness lives in the direction of rounding, and the magnitude of rounding must respect the verifier’s resolution*. The cost is  $2^{-96}$  of tightness, unmeasurable at certificate scale; the benefit is that a refusal now carries information — it indicts the claim, not the resolution. Two smaller dividends follow. Dyadic endpoints are exact rationals — an `f64` is a dyadic rational — so the checking side compares them in exact arithmetic, and a certificate that confines itself to the dyadic grid never smuggles a rounding into its own statement. And grid-aligned emissions keep denominators uniform across a certificate’s rows, which the exact tier’s shared-denominator representation (section 18.1) rewards directly.

**The receipt.** Workshop record: the continuous-latents certifier behind the counterexample above landed with thirteen artefacts accepted under truth containment, thirteen mutants refused at their designed loci, and a twenty-six-case property layer — on the grid-clearing emission discipline. The lattice constants above ( $2^{-256}$  checker resolution,  $2^{-96}$  emission step, decision depth 16–64) are that campaign’s numbers; its artefacts migrate to the public repositories with their campaign, per the preview note.

## 18.3 A Lane May Change Cost, Never Verdicts

**The problem.** Multi-architecture fast paths rot in a characteristic way: not silent breakage but *silent divergence*, an optimized lane that is almost always equal to the reference. Hand-vectorized code that must be faster by assumption — and equal by assumption — is how fast-path crates decay. In a system whose outputs face a checker, a divergent producer-side lane wastes campaigns; a divergent screening lane on the checking side is a soundness incident in waiting.

**The technique.** The shared-kernels repository (`maitria-coalition/kernels`) binds every kernel to one law: *an acceleration lane may change cost, never verdicts*. Three structural consequences. *Reference first*: every kernel ships a portable scalar reference, written for obviousness, always compiled — the reference is the semantics; lanes are the economics. *Receipts before dispatch*: a property-based differential battery gates every lane in CI, but passing the battery earns a lane only existence; a lane becomes its architecture’s default only with a measured receipt on real hardware, committed to the repository — and a lane that loses to the reference on its own target stays available, un-dispatched, and marked. *Fit-detection, never approximation*: fixed-width paths detect inputs they cannot represent exactly and refuse them to the caller’s promotion ladder; no rounding exists on any verdict-relevant path. For JIT-compiled device lanes there is a fourth: the same kernel source can compile branch-free under an offline pipeline and branchy — an order of magnitude slower — under a runtime pipeline, so every device lane names its *pipeline of record*, acceptance benches run that pipeline, and the disassembly branch count is printed at build time and recorded in the receipt as a watched number.

**The receipt.** The founding receipts of the coefficient-sweep family, committed under receipts/ in the kernels repository: the NEON lane at  $1.47\text{--}3.00\times$  the reference across shapes on a Grace-class aarch64 workstation, the AVX2 lane at  $1.25\text{--}3.96\times$  on a Skylake-W Xeon — with the receipt’s own candid reading attached, that the wins are modest at the largest sizes because a streaming i64 scan leaves cache and becomes memory-bandwidth-bound. The dispatch code cites those numbers, not the intuition they corrected. And the batteries earn their keep in both directions: the GPU interval family’s *first* battery run falsified the oracle, not the kernels — a naive exact-rational reference had missed IEEE 754’s signed-zero rules [120] (an exactly-cancelling round-toward- $-\infty$  addition yields  $-0.0$ ; an exact-zero product carries the XOR of the operand signs). The device was right; the oracle now spells the exact-zero cases out, and the repaired family ran sixteen-for-sixteen green at a hundred property examples each — a battery its committed receipts have since grown to thirty-three properties, still all green at the same hundred. Exact rationals carry no signed zero, so an exactness oracle for float behaviour must state IEEE’s sign semantics explicitly — a differential battery is symmetric, and the symmetry is a feature.

## 18.4 The Babysitter Thread

**The problem.** An exact producer grinding a large obligation frontier can be legitimately silent for minutes: no intermediate result is trustworthy enough to print, and the hot loop has better things to do than I/O. But at an operator’s terminal — increasingly, an operating *agent’s* terminal — “no output for minutes” is indistinguishable from “hung,” and the rational response to a hung-looking grinder is to kill it, wasting exactly the work the silence was hiding. The doubt is the cost: it can be resolved only by waiting longer or killing sooner, and both resolutions are expensive. Classic optimization-solver CLIs solved this decades ago: an iteration line, about once a second.

**The technique.** The toolkit’s convention: any hot loop expected to run beyond about a second reports progress to standard output at least once per second — iteration count plus whatever else is cheaply at hand (objective, residual, cells retired). The implementation keeps the reporting out of the loop’s way: the hot loop maintains *only counters*, written with relaxed atomic stores — no I/O, no clock reads, no timing branches on the hot path — while a *babysitter thread* wakes on a system timer about once a second, reads the counters, and prints. Where the loop body is already chunky, the degenerate inline form suffices: consult the clock only every  $N$ th iteration and print when a second has elapsed — the event-loop engine in `crates/mtk-eventloop` does exactly this in its replay path (every 64th application, one elapsed check) and rate-limits its per-pass progress lines to the same once-per-second cadence, with the final line always printed. Where a verb’s standard output is a machine-consumed data channel, the collision is flagged and the progress line moves — never silently dropped.

**The receipt.** The convention entered the toolkit the usual way: a long exact-tier run drew a “no sign of progress” report, and settling that doubt cost more than the instrumentation ever would have. The fix is as close to free as instrumentation gets — a relaxed store per iteration and one thread sleeping on a timer — and both forms are landed machinery in the mtk repository. The exact solver loops carry the full form (`crates/mtk/src/progress.rs`: two relaxed counters, threaded as an optional argument so that opting out costs nothing, with the `lp-solve` verb’s exact path spawning the once-per-second monitor); the event-loop engine’s replay path carries the inline form (`crates/mtk-eventloop/src/engine.rs`). The surface also crosses the language boundary. The toolkit’s TypeScript bindings expose the same counters as a polling handle over asynchronous solve variants; JavaScript gives the babysitter and the baby one thread to share, so the solve must leave it before any timer can read a counter mid-grind. The printing monitor stays on the consumer’s side of the boundary, where a collision with a machine-consumed output channel is fixable at the call site rather than at a process boundary. One detail is worth copying: a test in each ticking module, on both sides of the language boundary, asserts both that the counters move and that their presence changes no outcome — the same run, bit-identical, with and without the observer. The pearl is the asymmetry: the counters cost nanoseconds per iteration; their absence is priced in killed runs.

## 18.5 A Certificate Is Database Content, Not a File Format

**The problem.** Every bespoke certificate file format breeds an ecosystem tax: one parser per consumer, version skew between them, vendored readers drifting from the spec, and an interchange layer that slowly comes to carry semantics nobody proved anything about. The toolkit’s development lineage paid this tax once — an early binary certificate format grew four independent readers before it was deliberately retired — and the replacement is a structural decision, not a better format.

**The technique.** Certificates are ordinary rows in the logical database: columns of exact scalars, tensor-valued content where the payload is genuinely tensor-shaped, stored under the certificate theory that the `qtsl` repository defines as data (`theories/Qtsl.geolog`, extending the Bernstein Logic proof tower of `theories/BernsteinLogic.geolog`), in the same content-addressed commits as everything else. There is no intermediate certificate file format to version, so there is none to drift; a checker’s input is a sealed commit body, and the same bytes serve every consumer — the production engine’s incremental monitoring, the certified-checker route, the reflection route into a proof assistant’s kernel — with no translation step left to audit. Merge is set union plus re-derivation, and provenance questions (*who asserted this row, and did anyone assert its contradiction?*) are structural properties of signed content-addressed commits rather than per-format afterthoughts. What remains outside the database is deliberately thin: the untrusted tiers exchange proposals and refusals as CBOR shapes in a dependency-free types crate (`CONTRACTS.md §1.2` in the `mtk` repository draws the boundary: witness interchange is *not a proof format*), so the producer’s conveniences can evolve freely without a byte of them leaking into the checked surface’s semantics.

**The receipt.** The interchange layer’s golden vectors decode a committed certificate whose payload carries 55-digit big-integer fractions and round-trip it losslessly through the `v0` shapes (`crates/witness-types/tests/golden.rs` in the `mtk` repository) — exactness surviving serialization is a test, not a hope. And the next pearl depends on this one: canonical content is what makes byte-identity a meaningful instrument in the first place.

## 18.6 Byte-Identity Is a Conformance Instrument

**The problem.** Cross-platform reproducibility for numerical systems is conventionally stated in tolerances — “agrees to  $10^{-9}$  across machines” — which reintroduces judgment exactly where an audit wants none: who chose the tolerance, and what drifted inside it? A certificate-producing system can demand more. If the certifying path is exact and the emission is canonical, the correct cross-platform claim is not agreement within tolerance; it is *the same bytes*.

**The technique.** Make the producer deterministic by construction — exact arithmetic on the certifying path, so no platform’s float behaviour can enter (section 18.1); fixed iteration and emission orders, so no hash-map enumeration nondeterminism survives; canonical serialization (section 18.5) — and cross-silicon conformance collapses to `cmp`. The split this buys is exactly the split the system’s trust story wants: the *verdict* column of any re-run table must be identical across machines, while the *time* column is allowed to vary and thereby becomes a genuine hardware measurement instead of a confound.

**The receipt.** The reproduction spine’s semiconductor-fab case study (the worked example of chapter 17; battery and receipts in the `semicon/` tree of `maitria-coalition/qtsl-experiments`) was re-run end-to-end on two boxes of different instruction sets — a Grace-class `aarch64` workstation and an `x86-64` EPYC cloud instance. Every emitted certificate came back byte-identical to the committed fixtures on both: ten of ten fluid-scheduling certificates, with the certified slack values matching as exact rationals; six of six station-cover certificates by SHA-256; the policy-separation numbers reproduced as identical exact rationals ( $\epsilon = 1/43200$  against  $1/38880$  at the near-capacity operating point); and the deliberate failure probes — the honest-stop cases — still failing correctly on both machines, producer face and checker-mutant face alike. The checker battery ran all sixteen positive fixtures and all thirteen mutants to their expected verdicts on both boxes. The timing columns, meanwhile, differed by a uniform  $1.7\text{--}1.9\times$  single-core factor across producer walls and check kernels — a bridge measurement that classifies every cross-box timing delta as

hardware economics, with evidence, rather than leaving it to argument. Determinism turned an entire re-validation campaign into a column of *identical* plus one real hardware number.

Six decisions, one shape: in a system where every claim must survive an independent checker, the engineering wins go to whoever moves judgment out of the pipeline and into artefacts — exactness where floats were assumed, grids where guards were assumed, receipts where intuition was assumed, bytes where tolerances were assumed. The measurements above are what those trades cost and what they paid; the repositories carry the artefacts to re-run them.

# Cookbook for Agents

---

DRAFT

This chapter is the toolkit’s proof-production cookbook: moves in the Pólya shape — the move, its recognition conditions, a worked example with receipts, the failure mode it prevents, exercises — re-derived from *How to Solve It* [200] for minds that produce machine-checkable certificates. The intended reader is a large language model (or any capable agent) doing formal verification and heavy engineering; a human reads it profitably as the toolkit’s operational philosophy stated concretely. The register follows from the founding intent: a meta-insight that could once only be pattern-matched through years of accumulated practice can now simply be *stated* to an agent, in the agent’s native language, and applied faster for being explained.

Every pattern carries the same five rubrics. *The move*, stated once at full generality. *When it applies*: the recognition conditions — how you notice, mid-task, that this is the situation you are in. *Worked example from the record*: a real incident from the workshop record that produced this toolkit, receipts included, so the reader can go verify rather than take the chapter’s word — itself one of the cookbook’s moves: a claim worth acting on ships with an artefact positioned to contradict it. *The failure mode it prevents*: what happens, concretely, on the path where the move is not made. And *exercises*: open legs from the producing campaigns’ own backlogs at this preview, so that working an exercise produces value, not homework. Artefacts named in the examples migrate to the public repositories as they graduate; per the preview note at the front of this volume, treat a mention as a statement of what exists, not yet a link. Status words (“shipped,” “proposed,” “in design”) are as of this preview.

The workshop’s cookbook has already grown past this chapter: two further moves graduated after this preview’s cut (one on charters as falsifiable predictions, one a proof-assistant transparency lesson), and a strong candidate — adversarial review with planted doubts — stays deliberately unwritten here, because its authoritative statement is a live operating document in the workshop, with measured hit rates across the review campaigns that shaped it, and a book copy of a live norm would drift from the norm. Each will be written from its receipts when they migrate. Behind them, a harvest queue of roughly ninety further candidate moves waits its turn.

## 19.1 Sloppy Proposer, Exact Disposer

**The move.** Split every computation whose result must be trusted into two roles with an explicit boundary:

- a **proposer** — fast, approximate, unverified, and structurally *untrustable*: a float library, a validated-numeric package, an ML search, an SMT heuristic, your own quick script. It produces candidates: a region, a bound, a witness, a decomposition, a step size.
- a **disposer** — exact, minimal, independently implemented. It re-derives, from the candidate data alone, everything the certificate asserts (exact- $\mathbb{Q}$  arithmetic, from-scratch identity checks) and accepts or rejects. Nothing the proposer computed appears in the trusted conclusion; only what the disposer re-derived.

Then police the boundary **in both directions**:

1. Proposer arithmetic never enters the certificate. The trusted computing base contains the disposer and nothing else; the proposer is trusted only *as a search heuristic*, where being wrong costs retries, never soundness.
2. Disposer arithmetic never enters the proposer’s inner loop. Exact computation inside a search loop is pure waste: the loop’s job is to find a candidate worth checking, and it should be as cheap as

correctness-irrelevance allows. The division of labour is the point — a proposer made rigorous is as much a design error as a disposer made sloppy.

This is the book’s assurance stance (chapter 1) applied at the scale of a single computation, and the producer stack is shaped by it end to end: every GPU kernel row returns witness-typed output built for the exact tier’s disposal (chapter 18), and the checker at the bottom (chapter 15) is the disposer of last resort.

### When it applies.

- Any time a fast-but-unverified computation must feed a certificate whose soundness has to be airtight. The recognition question: “does the assurance story currently require this library/model/script to be bug-free?” If yes, restructure so it only has to be *useful*.
- Any time you notice exact or expensive computation inside a loop that exists to search. The recognition sign is a profiler line: the search dominating wall-clock with arithmetic whose precision the final verdict never uses.
- When choosing whether to “just trust” an established rigorous-numeric or solver library. The relevant question is not whether the library is good (it usually is) but whether its *output representation* already matches something your checker can re-verify — in which case de-trusting it is nearly free.

**Worked example from the record.** The validated-ODE de-trusting ladder: take enclosure claims from CAPD — a well-regarded C++ validated-numeric library for rigorous ODE integration — and re-found them on an exact checker, so that the assurance story never rests on trusting C++ interval arithmetic. The architecture is the move verbatim: three certificate species in which the proposer of every candidate — CAPD, an in-house float Picard iterator, anything — is untrusted by construction, and the checker re-derives all sequent polynomials from the candidate data by exact  $\mathbb{Q}$  arithmetic. Validity of a proposed flow tube is a checkable fixed-point inclusion (the Picard operator maps the candidate box into itself — the a-posteriori validation architecture formalized, kernel and all, by Bréhard, Mahboubi, and Pous [1]), so the checker never integrates anything — it verifies inclusion-invariance of what the untrusted integrator proposed, with zero per-instance quantitative side conditions: no Lipschitz constant, no contraction factor, no step-ratio condition in any certificate.

Both directions of boundary-policing have receipts:

- **Direction 2, learned the expensive way.** The first proposer implementation ran exact Bernstein computations inside its candidate-search loop over radius and error-matrix parameters — measured at roughly forty seconds per pass of pure waste, since the disposer re-derives everything anyway. The campaign’s own retrospective names the division of labour as one of its surprises: the lesson was not “be rigorous” (the pipeline already was, at the disposer) but “stop being rigorous in the wrong place.”
- **Direction 1, cashed out when the real library arrived.** CAPD, vendored and driven through the frozen proposer interface, checker untouched: the exact- $\mathbb{Q}$  end box agreed with CAPD’s uncertified claim to three decimals with a tube radius about  $50\times$  tighter — the cost of de-trusting was approximately zero enclosure quality (wall-clock about  $5\times$ , spent in the checker, which is the one place spending is correct). And the certified envelope *extended*: a Van der Pol step size the in-house float proposer could not certify became certifiable with CAPD proposing. An isolation probe attributed the remaining failure wall to the in-house proposer’s own search loop, not to CAPD — a diagnosis only available because the interface made proposers interchangeable.

Note what interchangeability bought beyond soundness: upgrading the proposer from quick in-house script to best-in-class library was a pure plug-in, no re-verification of anything, because the trust boundary never moved.

### The failure mode it prevents.

- **Trusted-base bloat:** the assurance story “the theorem is only as trustworthy as the library plus the compiler run” — which is CAPD’s own openly stated architecture, and precisely the thing being escaped. Every trusted component is a standing liability that must be re-audited whenever it updates; a proposer never needs auditing at all.

- **The dual waste:** search loops that run at certificate precision, making exploration the bottleneck for zero soundness benefit. This one is insidious because it *feels* virtuous — rigour everywhere — while actually signalling that the boundary was never drawn.
- **Un-upgradeable pipelines:** when proposer and verifier share arithmetic (or code), swapping in a better search engine means re-validating the world. With the boundary drawn, proposers compete and the checker stands still.

### Exercises.

1. **The jet-transport adapter.** CAPD's `Cn0deSolver` computes derivatives of the flow map (jets). The adapter interface is frozen and the ladder's first-rung sequent layer is jet-ready; wire `Cn0deSolver` through the same seam, checker untouched. Success condition: goldens accept with CAPD-proposed jet enclosures; the checker diff is empty.
2. **Settle the flagged hypothesis.** The adapter's arrival recorded that one benchmark's certifiable-step wall moved *inward* under CAPD, with a stated-but-unverified mechanism (centred forms losing a cancellation under the checker's crude absolute-value bound). Design the two-cell experiment that confirms or refutes the mechanism; if confirmed, the fix belongs in the disposer's bound, not the proposer.
3. **Generalize the isolation probe.** The probe that attributed the residual wall to the in-house search loop was built bespoke. Extract the pattern — swap proposers across the frozen interface, hold the disposer fixed, bisect which side owns a failure — into a reusable harness verb for any proposer/disposer pipeline.

## 19.2 Certify the Honest Stop

**The move.** When a line of attack ends — the rate cannot be improved, the constant cannot be sharpened, the method genuinely runs out — do not shrug and move on, and do not quietly ship the weaker thing as if it had been the goal. **Prove the stop.** Convert “we couldn't push further” into one of three certified endings, and record which one you are in:

1. **The claim past the stop is false.** Produce the witness (a concrete counterexample instance) *and*, where the machinery permits, a certificate-side proof that no valid certificate of the stronger claim exists (e.g. any candidate decomposition is forced into an inadmissible component). Then the stop is a theorem, not a fatigue report.
2. **The claim is true but this method cannot reach it.** Name the missing ingredient as a first-class object — a new prior family, a stronger bridge lemma, a representation the format lacks — so the stop becomes a scoped successor leg rather than a vague wall.
3. **The claim is true at a boundary value.** Certify the boundary from both sides (the bound holds at  $c$ ; a witness attains  $c$ ), so the constant ships as sharp rather than as “the best we found.”

In all three cases the artefact records the stop with the same rigour as the positive results — ideally *inside* the same certificate and test battery, so a future reader (or a future you, or a cheaper model retrying the problem) cannot re-open the question without meeting the proof.

### When it applies.

- Whenever a sweep, ladder, or optimization plateaus and you are about to write “we achieved  $X$ ” for the  $X$  you reached. The recognition question: *is the plateau a fact about the problem or about your effort?* If you don't know, that is ending 1 to chase — the answer is usually cheaper than the next ladder rung would have been.
- Whenever you are tempted to soften a claim's statement so that what you proved matches it. Softening is sometimes right — but only with the un-softened claim's status recorded (false? open? method-blocked?).

- When banking machinery or priors for future use: an input that turned out to be *unconsumable* (its only consumer is a false claim) is a result about the problem’s structure, worth the two sentences it costs to record.

**Worked example from the record.** The Kuramoto–Sivashinsky energy certificate, fourth target of a campaign producing exact-rational, independently replayed dissipation certificates for PDEs. The campaign’s earlier targets had certified decay *rates* — viscous Burgers at the sharp rate  $\frac{d}{dt}E \leq -2\nu E$ . For Kuramoto–Sivashinsky on the marginal domain  $\mathbb{T}_{2\pi}$  the analogous hope — any positive rate  $\alpha > 0$  — is **false**, and the artefact treats that falsity as a deliverable (ending 1, with ending 3 nested inside):

- **The witness:** at mode  $k = 1$  ( $u = \varepsilon \sin x$ ) the dissipation form  $k^4 - k^2$  vanishes and the nonlinearity is energy-neutral, so  $\frac{d}{dt}E \leq -\alpha E$  fails for every  $\alpha > 0$ . One line, checkable by hand.
- **The certificate-side impossibility:** the producer carries an assert that any nonnegative-weight decomposition of the  $\alpha$ -remainder forces weight  $-\alpha$  on the  $u_2^2$  square — unconditional in the free weight. The stronger claim is not merely un-found; it is un-certifiable in the calculus, and the artefact proves that.
- **The battery enforcement:** a mutant recomputes *everything* consistently at a positive rate — every jet identity, every replay green — and is rejected *only* by the negative weight. The stop is enforced in the executable spec (section 19.3): a future certificate claiming a positive rate on this domain will be refused by machine, not by memory.
- **The named residue** (ending 2): the artefact’s own stopping-point section states what the composed result is — energy monotonicity at the marginal domain, sharp, the strongest true statement for this functional on this domain, with the stop *provable* — and then names what the real literature benchmark ( $L > 2\pi$  mean-energy bounds, where energy genuinely grows through the unstable band) additionally requires: a background functional and a genuinely new prior family (Gagliardo–Nirenberg/interpolation rows). Its closing words are this section’s thesis in miniature: “named next leg, not tonight’s overclaim.”
- **The unconsumed input, recorded:** a banked spectral prior ( $\int u_2^2 \geq \int u_0^2$ ) is left unconsumed, on the record — the campaign notes its only would-be consumer is the false rate claim. Two sentences, and no successor will wonder why it sits unused.

A sibling specimen, same campaign, showing ending 3 in both directions: the Fisher–KPP certificate proves the invariant region  $[0, 1]$  is maximal by mutants — enlarged above to  $[0, \frac{9}{8}]$ , all bookkeeping recomputed consistently, rejection comes only from a genuinely negative Bernstein coefficient that no subdivision can repair; extended below, the endpoint row itself fires. “The certificate cannot be strengthened past the true boundary in either direction” is a tested property of the checker, not a sentence in prose.

### The failure mode it prevents.

- **The shrugged dead-end:** an unrecorded stop is a question that reopens. Someone (often a cheaper agent, often you-next-week) retries the false claim, burns the same compute, and — worse — may “succeed” via a subtly unsound route precisely because nothing in the machine refuses it.
- **The laundered stop:** shipping the weaker claim in the stronger claim’s rhetorical clothing (“we certify decay” when the hoped-for rate silently became 0). The reader’s trust is spent on the discrepancy when they find it — and in adversarial review they will.
- **Effort-plateau mistaken for truth-plateau:** without the falsity/impossibility half, “sharp” means “we got tired.” With it, sharpness is a two-sided certificate and the constant is settled.

### Exercises.

1. **The symbolic-domain carriage.** Carry the domain length  $L$  symbolically through the Kuramoto–Sivashinsky certificate: for  $L < 2\pi$  the same form yields a *positive*-rate nonlinear decay; for  $L > 2\pi$  it yields nothing — the energy method genuinely ends there. Certify both sides of that boundary, making the method’s own limit an ending-3 artefact.

2. **The background-functional leg.** The named ending-2 residue: build the interpolation prior family (the first genuinely new prior species in the campaign) and attack the  $L > 2\pi$  mean-energy benchmark. The honest-stop record is the specification of exactly what is missing.
3. **Settle a flagged wall.** The CAPD adapter's arrival (section 19.1) left one certifiable-step wall's inward move as a stated-but-unverified hypothesis. Determine which ending it is: a true wall of the bound (certify it), or an artefact of a crude inequality (fix the disposer and move it back). Either way the stop stops being a guess.

## 19.3 The Mutant Battery Is the Spec

**The move.** A checker's meaning is not what it accepts — accepting the golden certificate is table stakes — but what it **rejects**. So specify the checker by building its rejections: a battery of *mutants*, each a certificate wrong in one deliberate, named way, each asserted to be rejected **at its intended check with its intended message**. The battery is then the executable specification of the trust boundary: every mutant is a theorem of the form “a certificate lying in *this* particular way cannot pass,” and the battery as a whole delimits what an ACCEPT verdict actually asserts.

Two disciplines make the battery a spec rather than a pile of negative tests:

1. **Consistency mutants are the genre that carries the spec.** The strongest mutants recompute *everything downstream of the lie consistently*, so that every identity, every replay, every side computation is green, and rejection can only come from the single row that carries the claim's truth. A mutant rejected by accidental earlier breakage (a malformed field, an arithmetic slip you didn't intend) tests nothing about the check you meant to test — which is why each rejection's *location and message* are asserted, not just the rejection.
2. **Cover the lie taxonomy, not just arithmetic.** Wrong numbers are the easy genre. The battery must also include: sharpness violations in **both** directions (claim strengthened past the true boundary / input weakened below it), laundered caveats (an obligation's status upgraded to one no receipt backs), provenance breaks (data whose justifying source is removed, dangling, or unlisted), structural smuggles (declaring only a slice of the term the side condition should see), and — where claims are mechanism- or context-scoped — transport violations (a true-in-context-A claim rewired into context B).

The same discipline runs at every tier of this toolkit. The rule catalogue (chapter 15) is its proof-theory face: the roster is machine-checked, every mechanized rule carries receipts, and the coverage dashboard up front is the candid map of what the assurance edifice does and does not yet refuse. The composition-pattern inventory (chapter 13) is its modelling face: the refusals do real work there too, encoded structurally rather than left to the modeller's vigilance.

### When it applies.

- Whenever you write a checker, validator, decoder, or replay tool whose ACCEPT someone will trust. If the mutant battery does not exist, the trust boundary exists only in your intentions.
- Whenever a checker gains a new check: the check's first artefact is the mutant it refuses. A check without a firing mutant is unfalsifiable — you cannot distinguish “this check works” from “this check is dead code.”
- When reviewing someone else's verification claim. “10/10 checks passed” is uninformative until you know what the 11th — the one built to fail — would have done. Ask for the battery before the benchmark.

**Worked example from the record.** The PDE certificate campaign of the previous section: exact-rational dissipation certificates for Burgers, Fisher-KPP, and Kuramoto-Sivashinsky, each with a Python producer and an independent exact-fraction checker sharing zero polynomial code, each shipping a battery with per-mutant rejection messages asserted. The taxonomy, one specimen each, all on disk:

- **Consistency + sharpness (above):** a Burgers mutant claims decay rate  $\alpha = 3\nu$  (true rate:  $2\nu$ ) and recomputes all bookkeeping consistently — all arithmetic passes and rejection comes only from the negative combination weight: the checker enforces the sharpness boundary, not mere self-consistency. The Kuramoto–Sivashinsky twin pushes a linear rate of 24 to 25 and is refused only by the forced weight  $-\frac{1}{16}$ .
- **Sharpness (below) + unrepairability:** the Fisher–KPP mutant widens the certified invariant region  $[0, 1]$  to  $[0, \frac{9}{8}]$ ; the endpoint rows still pass (any  $[0, b]$  with  $b \geq 1$  is inward at the ends) and the refusal comes from one genuinely negative Bernstein coefficient equal to  $f(\frac{9}{8}) < 0$  — no subdivision can repair it, so the battery proves the boundary is the true one rather than a resolution artefact.
- **Structural smuggle:** advection-smuggle mutants add a term the semilinear/jet-linearity side condition must see; every arithmetic identity passes and only the structure check fires — establishing that the side condition, not the arithmetic, is what excludes that class of false instance.
- **Provenance edges:** the Fisher–KPP deficit-decay remainder is the campaign’s first that genuinely needs a bounding box, and the box is supplied *by another claim in the same certificate* with an explicit provenance edge. Three mutants break the edge three different ways — source removed, dangling, supplier unlisted — and each is refused by the provenance check specifically.
- **Laundered caveat:** both laundering flavours — a hypothesis quietly dropped from the declared list, and an obligation’s status promoted to “proven” with no discharge receipt — are refused by the ledger discipline (section 19.4), tested both at the ledger and inside the discharge object.
- **Transport (the campaign’s centrepiece):** a mutant takes the linear-mechanism spectral-gap rate claim — true, certified, sharp *for the linear mechanism* — and rewires it onto the nonlinear flow, where mode-1 pumping makes it false. Every jet identity, weight, and spectral replay is green; rejection comes **only** from the mechanism-scoped premise-transport table. In the artefact’s own words: “the checker refusing a false theorem whose every checkable identity is true.” That single mutant is the spec of what the transport table means.

Scale receipts, for calibration: the three batteries run 31, 18, and 29 tests (29, 17, and 28 mutants respectively), messages asserted, with a combined regression replaying all three checkers green — and each battery was built within its target’s single working session: hours, not weeks.

### The failure mode it prevents.

- **The golden-only checker:** passes its examples, accepts a subtly-false certificate the day an adversary (or an optimizer, or a bug) produces one. Without mutants you have tested the happy path of a tool whose entire purpose is the unhappy path.
- **Dead checks:** a check that nothing exercises can be broken by refactor and no test notices. The firing mutant is the check’s liveness monitor.
- **Accidental-rejection illusions:** a battery whose mutants die of malformedness rather than of their intended lie certifies nothing — the dangerous mutant is the *well-formed* one, and only location-asserted rejections distinguish the two.
- **Unfalsifiable sharpness and scope claims:** “sharp,” “maximal,” “linear mechanism only” as prose adjectives, versus as mutants the machine refuses. The former decay into folklore; the latter are enforced.

### Exercises.

1. **The spectral wire rows.** When the jet certificate schema’s spectral wire family ships, write its battery *before* its first consumer: wrong-constant discharge, missing witness mode, transport onto an unlicensed mechanism — the taxonomy above, instantiated at the wire tier.
2. **Retrofit audit.** The neural-supermartingale certificate suite grew its mutant receipts incrementally across its campaign. Audit its batteries against the taxonomy: which genres are missing (transport? provenance? both-direction sharpness?), and add the cheapest missing genre with rejection locations asserted.

3. **The battery-of-the-battery.** The location-assertion discipline currently lives in test code by convention. Build the meta-check: a harness pass that runs each mutant, captures *which* check fired, and fails the battery if any mutant is refused earlier than its declared target — turning discipline 1 of this section from prose into a tool.

## 19.4 Declared-Prior Ledgers

**The move.** Every analytic fact your certificate **consumes but does not prove** — a functional inequality, a comparison principle, a semantic bridge between the certificate’s algebra and the theorem’s meaning — is carried by an explicit **ledger** inside the certificate, under a **closed status vocabulary**. Concretely:

1. **Declare, never absorb.** An unproven ingredient appears as a named entry (assumed, named-unproven, ...), not as an invisible premise folded into the prose or — worse — into the checker’s silence. The certificate’s ACCEPT then means: *these claims hold, conditional on this list*.
2. **Close the vocabulary and back every status.** The checker enforces that statuses come from a fixed set and that any status implying a proof has its receipt present and replaying green. An obligation promoted to “proven” with no receipt is a *rejected certificate* — laundering is a machine-refused move, not a style violation.
3. **Discharge as an arc, with a tie.** Because the ledger is explicit, an assumption can be discharged *later, incrementally*: a new certified object replaces assumed with a proof-backed status, and a **tie check** verifies the discharged object is the same fact the consuming row uses (same integrand, same constant) — so an internally valid proof of a *neighbouring* fact cannot silently license the claim.

The ledger converts “is this pipeline rigorous?” from a judgement call into a query: read the list. And it converts rigour-improvement from a rewrite into a diff: shrink the list, one discharge at a time. The rule catalogue’s coverage dashboard (chapter 15) is the same move applied to the assurance edifice itself: a declared, per-rule account of which correspondences are certified and which remain pending, in data rather than in reputation.

**When it applies.**

- Whenever a formal artefact meets analysis (or any outside theory): the bridge facts — Parseval, Grönwall, a comparison principle, a solution concept’s energy inequality — are exactly the ingredients a polynomial/arithmetic checker cannot re-derive. They must go *somewhere*; the only choice is ledger or shadow.
- Whenever you catch yourself writing “standard” or “well-known” next to a fact your checker never sees. Standard facts have names; name them in data, with a status.
- When planning a campaign: rungs you cannot yet prove are not blockers if they can be *declared* — the pipeline ships sound-modulo-ledger on day one, and the ledger is the campaign’s remaining-work list, machine-readable.

**Worked example from the record.** The Wirtinger discharge arc in the Burgers energy certificate. The sharp-rate claim  $\frac{d}{dt}E \leq -2\nu E$  needs the Wirtinger/Poincaré inequality  $\int u_1^2 \geq \int u_0^2$  for mean-zero data on  $\mathbb{T}_{2\pi}$  — an analytic fact the exact- $\mathbb{Q}$  jet checker cannot see. It shipped **declared-assumed**: a named prior in the certificate, with the mean-zero hypothesis’s *invariance* itself certified (a pure divergence row), and the declaration stated out loud in the campaign record. The pipeline was already refusing laundering at this stage: the Fisher-KPP sibling’s battery included both laundering mutants (hypothesis quietly dropped; status upgraded receipt-free), machine-refused.

A later session, the same day, discharged the prior *in-certificate*: on the torus it diagonalizes exactly, so the checkable kernel is the mode polynomial  $q(k) = k^2 - 1 \geq 0$  on  $|k| \geq 1$  — certified by an exact- $\mathbb{Q}$  shift row ( $q(1+t) = t^2 + 2t$ , nonnegative coefficients, covering every mode uniformly), with sharpness as a width-zero eigenvalue enclosure  $\lambda_1 \in [1, 1]$  (lower side the shift row, upper side the witness mode  $k = 1$ ). The ledger flips: *no assumed priors remain*. Three details carry the section:

- **The tie.** The checker verifies the consuming row's integrand is  $u_1^2 - c u_0^2$  at the discharged constant  $c$  — an internally valid discharge of a different constant cannot silently license the claim, and a consistency mutant enforces exactly that. Discharge without a tie is a new laundering surface; the arc closed it the same session it opened.
- **The residue is itself ledgered.** The discharge consumes four analytic bridge facts of its own (Parseval, derivative-coefficient, mean-is-coefficient-zero, termwise summation). They did not vanish into prose: each is a named bridge: entry citing its mathlib lemma at a pinned commit, citations checked live at writing time, with one remaining gap named (the  $H^1$  extension of the derivative form, which holds as cited at  $C^1$ ). The ledger got *shorter and sharper*, not empty by fiat.
- **Laundering mutants re-targeted post-discharge.** With a discharge object present, the new lie is tampering *inside* it, or claiming spectral-certified status without it; the battery grew nine mutants aimed at the ledger and the discharge both. The status vocabulary stayed closed the whole way.

Cost calibration, because trained priors on verification cost run years stale: the whole arc — declare, ship sound-modulo-ledger, discharge with sharpness, tie, re-target the battery — completed within one working day across three sessions. Declaring first did not slow the campaign; it is what *let* the campaign ship while the discharge waited its turn. And the banked bonus paid forward the same day: the discharge artefact pre-certified the higher-order siblings ( $q = k^4 - k^2, k^4 - 1$ ), which the Kuramoto–Sivashinsky target then consumed as its spectral priors.

#### The failure mode it prevents.

- **The silent assumption import:** a “verified” pipeline resting on an unnamed analytic fact — the reader believes the checker saw everything; the gap surfaces in adversarial review (or in production) as “what exactly does ACCEPT mean here?”, and the answer costs the pipeline its credibility even where it was sound.
- **Laundering under deadline:** statuses drifting upward (“assumed” → “known” → “proven”) across retellings, with no machine in the path to refuse the drift. This is the certificate-level twin of the documentation failure in which a distilled guess hardens into quoted law: the repair in both cases is provenance enforced at the artefact, not vigilance in the prose.
- **The wrong-theorem discharge:** proving a true neighbouring fact (different constant, different function space) and letting it license the claim — refutable only if the tie between discharge and consumer is checked, which is why the tie is part of the move and not a refinement of it.
- **All-or-nothing rigour:** without a ledger, “not fully proven” and “not shippable” collapse into one, and campaigns stall at their hardest lemma. With one, soundness-modulo-a-shrinking-list is a publishable, checkable state.

#### Exercises.

1. **The Lean bridge lemmas.** The four bridge: entries in the discharge (plus the linear-mechanism spectral-support obligation in the Kuramoto–Sivashinsky artefact) are named with mathlib citations at a pin. Formalize the statements as Lean lemmas against that pin, flipping each ledger entry from cited to proof-backed — and add the battery mutant that tampers with the new receipts.
2. **The named gap.** The derivative-coefficient bridge holds at  $C^1$  data; the  $H^1$  extension is an explicitly named gap in the ledger. Close it — part of the exercise is determining whether the gap closes at the pin or needs an upstream mathlib contribution.
3. **A new prior species, ledger-first.** The  $L > 2\pi$  Kuramoto–Sivashinsky benchmark needs interpolation (Gagliardo–Nirenberg-type) priors — the first genuinely new prior family since Wirtinger. Introduce them the ledger-first way: declared species with closed statuses and laundering mutants *from birth*, so the discharge arc has its rails before anyone attempts the discharge.

## 19.5 Cheap Before Expensive

**The move.** Before committing the expensive resource — a build, a rented-GPU run, a finer subdivision, a proof campaign, a frontier-model token stream — spend the cheap instrument that could make the expensive spend unnecessary, radically smaller, or better-aimed. The move has three forms, in ascending machinery:

1. **The cheap question.** Does the record, or a free qualitative argument, already settle it? Read the project log before the build; check for the monotonicity observation before assembling the sharp ladder. The cheapest ending to an expensive plan is discovering it already happened, or was never needed.
2. **The cheap pass.** When cost scales with a count (cells, claims, pieces, obligations), run the inexpensive consolidation *before* paying the per-unit price — and demand the consolidation be loss-free where the theory permits it (same bound, fewer pieces), so the saving is pure.
3. **The cheap measurement.** When two routes to the same certified quantity compete, race them at *equal budget* on a real instance before scaling either. “Which route wins” is an empirical question with a cheap experiment, not a doctrine — and the fair comparison is at matched spend, since anything beats anything given more budget.

Two boundary clauses guard the move. First, it orders instruments; it never licenses deferral — a plan that stops at the cheap instrument needs a stated mechanism for when the expensive one fires, not a vibe; and when the expensive machinery gets built anyway, it is *banked, not wasted*: retained explicitly for the sibling case where the cheap argument does not apply. Second, the currency is latency and aim, not primarily money: in a regime of abundant implementation capacity, what the move conserves is the time the expensive spend takes, the attention it occupies, and the risk of aiming it at a target the cheap instrument would have moved.

### When it applies.

- About to dispatch or build something whose success condition might already be satisfied. The project record is the cheapest instrument available, and the check extends to every dispatch, not only the ones that feel uncertain.
- About to turn a budget dial — subdivision depth, piece count, degree, machine-hours, review rounds — because the current answer is not tight enough. First ask: is there a cheap restructuring (a coarsen pass, a representation change) that dominates dial-turning? The recognition sign is a cost that scales like  $\mathcal{O}(h^{-k})$  against an error shrinking like  $\mathcal{O}(h)$ : the dial is the losing side of an exponent gap.
- Holding a certified artefact whose slack is visible (margins, lift values, mutant-refusal exponents): slack is prepaid budget, and a cheap pass can often spend it on consolidation with zero loss.
- Routing work to minds: at any date there is a quality/cost/speed frontier of available models, and selection is by context, not by rank — the cheap capable point first, the frontier model where context-understanding or taste binds. The same logic governs how much deliberation to request from a given model: effort is a dial, and the cheap setting is the right default for work that does not need the expensive one.

**Worked examples from the record.** **The consumed dispatch.** An overnight agent was dispatched toward what its brief framed as a live build: an exact certifying-tier GPU kernel family, on a rented machine. The agent’s first instrument was one read of the project log — which showed the tier had shipped *that morning* (fused exact Bernstein slot kernels, 11/11 device-versus-host-reference bit-exact, with two successor tasks already consuming them). Verdict: dispatch adjudicated consumed; a candidate follow-on was named without being fired; total agent runtime 132 seconds. What a rented-machine campaign would have re-built, a two-minute read retired.

**The slack-funded coarsen pass.** A family of fixed-shift projection-kernel certificates was born-certifiable with lift 0 — the theorem’s manufactured slack absorbed all float noise. That slack is prepaid budget, and a cheap coarsen pass spent it: one representative solution went from 640 uniform pieces to 26 nonuniform dyadic pieces (89 claims), *bound bit-identical*, lift still 0 — the receipts’ own headline was “coarsening pays

14 $\times$ .” Every downstream cost of that row (certify, reference-check, emit, fast-check, per claim) shrank by the same factor before any expensive tier ran. One detail worth copying: the coarsen pass’s excess ledger initially under-billed (an interpolant’s convexity overshoot went unbilled), and it was the pinned test suite that caught it — the cheap pass runs under the same verification discipline as everything else.

**Tube versus hull at equal claim budget.** A design note posed its own pricing question — a curved-boundary “tube” upgrade “pays exactly when hull conservatism is the binding loss — measure first” — and the measurement ran both routes to a certified enclosure of the same switching integral, same exact tier, budget counted in claims. At about 10 claims the tube already matched the hull’s 112-claim width; at 59 claims the tube was  $\sim 1300\times$  tighter than the hull at 237; matching the tube’s width by dial-turning the hull would extrapolate to subdivision depth  $\sim 17$ ,  $\mathcal{O}(10^5)$  claims. The receipts’ verdict — on this benchmark the tube wins by two to four orders of magnitude at every matched budget — was scoped to the benchmark, with both scaling laws measured. One cheap head-to-head, and the budget dial was retired as the losing instrument for this loss class *before*, not after, a  $10^5$ -claim campaign.

A sibling specimen from the proof side: a closed-loop encounter certificate needed “stays separated forever after exit,” and the author built the full ray-clearance LP ladder — then found the certified exit condition makes the exit face *recede*, so post-exit eternity is free model algebra on already-certified facts. The LP machinery was demoted as unnecessary for that class and explicitly retained for the non-receding sibling classes: the cheap question asked late still pays, and the expensive machinery, banked, is not waste.

### The failure mode it prevents.

- **The duplicate build:** re-doing shipped work because the record went unread. The cost is not only the spend — a re-built sibling diverges from the shipped one, and reconciling them later costs more than either.
- **Dial-turning into an exponent gap:** paying  $\mathcal{O}(h^{-k})$  for  $\mathcal{O}(h)$  relief because scaling the incumbent felt like progress and restructuring felt like a detour. The receipts above put real numbers on how bad this gets: five orders of magnitude of claims to match a route change.
- **Doctrine substituting for measurement:** “the sophisticated route wins” (or “the simple route suffices”) adopted from taste, when the equal-budget race costs minutes. The tube-versus-hull brief explicitly allowed the inverse outcome — the measurement declined it, and only the measurement could.
- **Thrift theatre:** the inverted failure — reading this section as “spend less.” The expensive spend is often correct; if you are an agent whose cost intuitions were trained on older tooling, your priors on verification cost in particular run stale and high (the receipts throughout this chapter say hours where the prior says months). The move is about what you learn *before* aiming the big spend, never about flinching from it.

### Exercises.

1. **The agreement-matrix verb.** The consumed dispatch above named a follow-on without firing it: a consolidated float-versus-exact agreement-matrix verb over existing machinery, its content currently distributed across two campaigns’ receipts. Build it as a standing cheap instrument (one CLI verb) so the cheap question “do the tiers agree, where, at what exponent?” costs one invocation before any future expensive exact-tier run. Success condition: the verb runs against the committed receipts and emits the matrix; its output for one known row matches the published receipt.
2. **Coarsening at degree 2.** The projection-kernel receipts state the boundary plainly: the degree-2 fixed-shift row is a-priori sizing only — no monotone theorem at degree 2 (the Korovkin boundary, measured in the same receipts as a step change in monotonicity violation). The coarsen pass is theory-backed only at degree 1. Determine whether a-posteriori coarsening pays at degree 2: coarsen, re-certify, compare bound and claim count against the uncoarsened row. Success condition: a new receipts row with pieces/claims/bound/lift columns, whichever way the verdict falls — an inverse outcome would be a finding rather than a failure.
3. **The next binding-loss measurement.** The tube route won where hull conservatism was the binding loss on a two-dimensional benchmark with one curved boundary. Before extending tubes

(higher dimension, multiple switching surfaces), run the pricing question forward: construct the next benchmark, measure the hull baseline's scaling first, and only build the tube generalization if the exponent gap is present there too. Success condition: a receipts-shaped table for the new benchmark with both routes at matched budgets — or the measured absence of the gap, banked as the reason the generalization waits.

## 19.6 Scope and Frame

**The move.** Every claim lives in a frame — a mechanism, an interface, a semantics under which its sentences are read — and most catastrophic errors in certificate work are not wrong identities but *right identities read in the wrong frame*. The move is to pin the frame as a first-class, machine-checked object before building, and then enforce scope in three places:

1. **Premises transport only where licensed.** A fact proven in one frame (one mechanism, one solution regime, one data class) does not follow the notation to a neighbouring frame. Record, per premise, the frames where it holds and the mechanism that carries it there — an invariance row, a bridge obligation — as *checker data*, so that using a premise outside its license is a refusal, not an oversight.
2. **Changes enter only through the seam.** When an untrusted component is upgraded or swapped, the modification's entire footprint is the declared interface; everything on the trusted side runs byte-for-byte unchanged, and that claim is grep-verifiable, not asserted.
3. **Out-of-scope reads go vacuous, never false.** When the frame itself is discovered ambiguous — the same certificate admitting two readings, one of them unsound — the repair is semantic before it is mechanical: declare the conditional reading normative (the certificate asserts its conclusion *given* its declared environment), so a certificate whose hypotheses cannot be jointly met claims nothing, rather than something false. Then add the mechanical check that makes the declaration well-formed.

The common discipline: the frame is stated where the machine can refuse against it. A frame that lives in prose (“this only applies to the linear case,” “don’t touch the checker”) decays into folklore; a frame that lives in a transport table, a frozen function signature, or a normative semantics section with its checker pass is enforced by machine. The composition-pattern inventory (chapter 13) runs the same discipline at the model tier: which certificates transport across a composite boundary, and which are refused, is part of each pattern's definition.

### When it applies.

- Any artefact with more than one mechanism, regime, or model of the same system — linearizations beside nonlinear flows, discrete beside continuum, per-piece beside global. The recognition question: “could every *identity* in this proof be true while the *theorem* is false, because a premise crossed a mechanism boundary?” If the answer is not obviously no, the transport structure is missing.
- Any planned upgrade of a component inside a verified pipeline. The recognition sign is the phrase “and we’ll just also need to tweak the checker” — the seam is about to leak; freeze the interface first and make the swap's footprint checkable.
- Any review finding of the shape “under reading A this is sound, under reading B it accepts a lie.” That is not a bug in a check; it is an unpinned semantics, and patching the check without declaring the reading leaves the ambiguity for the next consumer.
- At design time, before requirements: the frame question (“what kind of thing is this, really?”) outranks every detailed requirement, because a wrong frame silently poisons all of them. The workshop's own worst-case specimen was a requirements document written against an implicit wrong frame — the modelling substrate read as an expressive logic rather than as a logical framework — whose review verdict was that most of the work needed re-doing. The frame question costs a paragraph; its absence costs the document.

**Worked examples from the record.** **Mechanism-scoped premise transport.** The Kuramoto–Sivashinsky certificate of sections 19.2 and 19.3 certifies two decay claims on two mechanisms: the nonlinear flow (energy monotone, sharp at  $\alpha = 0$ ) and the linear mechanism restricted to modes  $|k| \geq 2$

(rate  $-24$ , sharp at mode 2). The spectral-gap premise is licensed for the linear mechanism *only* — under the nonlinear flow, mode 1 is pumped from pairs like  $(3, -2)$  and the premise is not invariant — and that license is not prose: every mode-exclusion premise carries a transport table keyed by mechanism (invariance-row kind for mean-zero, bridge-obligation kind for spectral support). The battery's centrepiece rewires the gap-sector rate claim onto the nonlinear mechanism: every jet identity, weight, and spectral replay is green, and rejection comes only from the transport table. Without the transport structure, nothing else in the certificate would have objected.

**The frozen seam under a proposer swap.** When the real validated-numeric library replaced the in-house float proposer (section 19.1, seen here from the scope side), the entire change entered through one frozen interface: the adapter builds its Taylor-model polynomial and feeds it through the frozen proposal entry point, and the exact fixed point, split-tree certification, and checker run byte-for-byte unchanged. The claim is grep-verifiable and was re-verified at this chapter's writing: the override parameter appears in the proposer module (the seam's definition) and the adapter's own files, and nowhere in the checker — the checker's text is untouched by construction, not by promise. The payoff compounds: because the swap's footprint was the seam, an isolation probe could later attribute a residual certification wall to the in-house proposer's search loop rather than to the library — a diagnosis that only type-checks when proposers are interchangeable behind a frame that never moved.

**Vacuous, not false.** An adversarial review round found that a new integral-monotonicity rule in the jet certificate schema, read under plain all-pre-valuations sequent semantics, admitted a false ACCEPT: a precondition constraining a bound integral wire, plus free-sign equality cancellation, licensed a conclusion no trajectory satisfies. The repair came in the order this move prescribes — semantic half first: the contract declares the binding-environment reading normative (a certificate asserts its sequents over environments satisfying its preconditions *and* every binding it declares — the declared-hypothesis pattern), under which the attacking certificate makes the hypothesis set unsatisfiable and the certificate *vacuous* — never a false assertion, because under this semantics no environment is claimed. Then the mechanical half: a new certificate-global binding-functionality pass (duplicate bindings of one wire reject; the negative control fires in isolation) makes the declared environment a well-formed function of wires. The residue is scoped rather than hidden: until the registered-environment lane ships, a consumer composing these certificates owns the hypothesis-set satisfiability check the same way it owns assumed rows — stated in the normative section, where a composer will meet it.

### The failure mode it prevents.

- **Premise smuggling:** a true lemma licensing a false theorem across a mechanism boundary. This is the failure that green batteries cannot catch from below — every constituent identity replays — which is why the transport table has to exist as its own refusal channel.
- **Seam leak:** an “upgrade” that touches the trusted side “just a little,” after which nothing about the pipeline is a plug-in and every future swap re-opens verification of the world. The byte-for-byte-unchanged claim, grep-backed, is what keeps upgrade cost at zero on the trusted side.
- **The silently-false certificate:** an artefact sound under its author's intended reading and unsound under the reading a consumer will actually use. Declaring the semantics normative in the contract — and making the unsound reading *forbidden* rather than merely undiscussed — converts a latent soundness hole into a documented conditional.
- **Frame-blind requirements:** detailed specification against an implicit wrong frame, discovered at review, fixed by “most of this needs re-doing.”

### Exercises.

1. **The registered environment.** The jet schema names the successor leg for its own residue: carry the declared binding set as first-class certificate data (a registry object) with a sound existential-elimination/composition rule, so consumers compose certificates without carrying the conditional semantics by convention — the frame promoted from normative prose to checked data, this section's move applied to its own example. Success condition: two certificates composed through the rule, with a mutant pair (a composition whose environments conflict) refused at a named check.

2. **Transport tables as shared machinery.** Mechanism-scoped premise transport currently lives in the Kuramoto–Sivashinsky artefact’s checker. Extract it into the PDE campaign’s shared checker machinery so the Burgers and Fisher–KPP artefacts consume the same transport module — the fan-out built it once where it was needed; the unification makes it the family’s frame discipline. Success condition: all three batteries green through the shared module, plus one new transport mutant per retrofitted artefact.
3. **Unrepresentable out-of-frame states.** The modelling substrate’s tensor-contraction definition (chapter 5) was deliberately ratified in the form whose side condition — every un-hit index is an output — makes the value-relevant free choice (a dropped axis silently scaling results) unrepresentable rather than discouraged; the side condition is exactly the proof-irrelevance theorem. Realize contraction rows with that condition enforced by construction, and write the property test that witnesses proof-irrelevance (no auxiliary choice affects any value). Success condition: the lowering rejects ill-framed index maps at the type/row level, and the property test runs green against the reference semantics.

## 19.7 Separate the Timescales

**The move.** When a system’s rates split into well-separated bands, do not pay the stiffness tax in the checker — restructure the *proposal*. Timescale separation is a **producer strategy**: everything below lives in the untrusted lane and in certificate *structure*; the checker never learns what “stiff” means, and the separation parameter  $\varepsilon$  enters certificates only ever as an exact rational coefficient in rows, never as a concept — no new rule family, no new trust surface. Four sub-moves, run in order:

1. **Diagnose** (cheap, float): decide whether you are in the situation at all (recognition signs below). The diagnosis routes; it is never a claim.
2. **Factor** — reparameterize into fast/slow coordinates, as rungs of the toolkit’s reparameterization ladder. The first rung (shipped) is eigenmode coordinates: the modal matrix of the linearization is float-proposed and dyadic-snapped — the proposer/disposer pattern again — with the declared inverse verified by exact multiplication and the pullback identities replayed, so the frame travels with the certificate as an interface hypothesis whose identities the checker replays. The eigenvector matrix is the standard fast/slow splitter, and it costs nothing to de-trust. Higher rungs cover patch-local slow sets (per-patch affine; chart maps with certified-positive denominators) up to the ladder’s ceiling — hypernet maps for genuinely nonlinear slow manifolds, where the reparameterization is itself certificate content cited by digest. The ceiling is frontier at this preview: named, wire-format slot reserved, semantics awaiting their first consumer.
3. **Witness** — make “separated” a *checkable claim*, not an assumption. Two readings, used per what your matrix admits. The quadratic-form/Lyapunov reading (shipped): a fast-block rate floor  $\alpha_f$  via positive-semidefiniteness rows ( $P_f \succ 0$ ,  $Q_f - \alpha_f P_f \succ 0$ ), a slow-block rate ceiling, and the **gap row**  $\alpha_f \geq 2r\alpha_s$  as one exact comparison — and this reading works for nonsymmetric linearizations, which is the generic case. The eigenvalue reading (proposed, not shipped): certified spectral windows and an inertia rule — eigenvalue *counting* across shifts, the one conclusion shape the shipped roster does not span. When those ship, “the spectrum splits into  $(-\infty, -1/\varepsilon] \cup [-c, 0)$ ” becomes a specific certified sentence.
4. **Compose** — certify the blocks separately, then buy the coupled conclusion with the classical two-timescale composite  $W = w_s^T P_s w_s + \lambda w_f^T P_f w_f$  (Khalil, *Nonlinear Systems* [136], ch. 11, in linear-quadratic form). For polynomial and linear blocks the composite’s rows are ordinary conclusions on the full coupled system — the weighted sum *is* the certificate, and the weight  $\lambda$  is the producer’s small-gain balancing act, float-searched and exactly disposed. The general rule family is in the catalogue: SMALLGAIN (chapter 15), the calculus’s feedback-composition rule, which elaborates to a single SYZGY node whose exact conclusion identity at weights  $(1, \lambda, 1, 1)$  makes the cross-supplies cancel by construction — nothing fixpoint-shaped survives to checking time. Timescale separation is the special case in which the gain asymmetry makes the small-gain product easy: the fast block’s gain to the slow one scales like  $1/\alpha_f$ , so a real gap buys the composition its slack. And carry **the full error term**: whatever the slow-manifold or modal-frame approximation leaves over is a *certified remainder* inside the composite rows, never a dropped term. In the linear case this remainder is

literally visible — the exact off-diagonal entries the dyadic snap leaves in the modal frame. In the nonlinear case it is a certified enclosure of the approximation error: Taylor models today, with a fancier-approximants ladder (Chebyshev models [42], Remez with a-posteriori error certification, Padé with certified-positive denominators) in design at this preview.

**When it applies.** Recognition signs, each a cheap float-lane probe:

- **Eigenvalue-ratio probe:** eigenvalues of the linearization at a few representative points; a ratio  $\gtrsim 10\times$  between rate bands is the signature (one eigvals call).
- **Enclosure anisotropy:** cover refinement concentrating splits along particular directions everywhere — cells forced small in two axes at once by a skewed feature is exactly what a reparameterization fixes.
- **Step-size collapse:** an explicit integrator's stable step is orders of magnitude below the timescale of the observables you care about — classical stiffness, and the reason the certificate's cover would otherwise inherit the fast timescale globally.
- **Search-space conditioning:** certificate searches starving because coordinates live at wildly different scales. A measured instance from the workshop record: an Adam-driven certificate search starving on value ranges spanning 1 to  $10^6$ , fixed by a coordinate-scaling knob — the same pathology one level up, in the proposal lane's own dynamics.
- **The domain says so:** filters, controllers, chemical networks, neural dynamics — fast transient plus slow drift is the modal architecture of engineered and biological systems both. The workshop's worn witness is a deployed interactive-tracking system whose fast loop runs at 72–120 Hz against a 0.03–1 Hz slow loop, three orders of magnitude apart, named in its own documentation as the decision everything else rests on.

**Worked example from the record.** A deliberately linear toy, taken end to end through all four moves on shipped machinery: a two-fast/one-slow coupled linear system — slow rate  $\sim 1$ , fast rates  $\sim 64, 80$ , all-dyadic entries — exact throughout:

- float eig proposes the modal matrix; dyadic snap at  $2^{-12}$ ; exact inverse declared; the checker replays  $T \cdot T^{-1} = I$  and  $\tilde{A} = T^{-1}AT$  in  $\mathbb{Q}$ ;
- the snap's leftover off-diagonal coupling ( $\sim 7 \times 10^{-3}$ , exact) is the certified remainder, carried inside the composite;
- fast rate floor  $\alpha_f = 117097/1024$  through the *unmodified* checker, slow rate  $\alpha_s$  exact (a  $1 \times 1$  block's rate is one number), gap row  $\alpha_f \geq 2 \cdot 32 \cdot \alpha_s$  — certified per-state ratio  $57.9\times$ ;
- the two-timescale composite with  $\lambda = 8$  from a 12-point float search: composite rate  $\alpha_c = 455/256 \approx 90\%$  of the slow quadratic bound — the slow mode governs, which is the separation story's signature;
- 0.81 s end to end, a 554-byte certificate, 3/3 producer refusal probes and 8/8 checker mutants refused. The probe worth naming: cranking the back-coupling flips the slow mode *unstable* (the Schur-complement correction crosses zero) and the pipeline refuses at the exact modal row — the classical quasi-steady-state trap, caught by arithmetic rather than by vigilance.

The toy is deliberately linear — every claim rests on rows that exist at this preview. What the linear case cannot exhibit, and the frontier behind it: hypernet slow-manifold reparameterization (frontier), the eigenvalue-reading witness (proposed), and nonlinear certified remainders (in design). Each item names work in flight.

**The failure mode it prevents.**

- **Paying the stiffness tax in the cover:** without the factoring, a certificate over the coupled system inherits the fast timescale everywhere — cell budgets explode along directions the slow claim never needed. The reparameterization moves the tax into one exact similarity replay.

- **The quasi-steady-state trap:** classical singular-perturbation practice *assumes* the fast subsystem settles and substitutes its equilibrium — sound only under conditions (attractivity, weak back-coupling) that the classical workflow rarely certifies. The witness sub-move makes exactly those conditions the checkable content; the toy’s refusal probe is the trap sprung on purpose.
- **Monolithic non-reuse:** one big Lyapunov certificate for the coupled system is re-derived from scratch whenever either block changes. The composite factors the work: the fast block’s certificate is a reusable component, and only the small-gain arithmetic re-runs when the slow side varies — the same economy the assume-guarantee layer exists to buy (chapter 13), arriving here through the gap.

### Exercises.

1. **Land the eigenvalue reading:** the inertia and spectral-window rules are scoped with priced proof obligations in the workshop record. When they ship, upgrade the toy’s gap row to a certified spectral-window sentence and re-run the mutant battery.
2. **Certify a worn witness:** take a production system you operate that already runs a fast/slow split as engineering practice (the tracking-filter shape above). State the two loops as a two-mechanism system, witness the rate gap, and compose — the first deployed-system instance of this section.
3. **Van der Pol at large  $\mu$ :** the classic nonlinear two-timescale system. The slow manifold is a cubic — mid-ladder territory, with the approximants ladder’s certified remainder as the error term once it ships. Success condition: a certified relaxation-oscillation enclosure whose cover is coarse along the slow manifold.
4. **Timescale  $\times$  parameter box:** compose this section with the campaign’s parameter-boxed oscillator artefact (uniform decrease over a damping box) — a fast/slow system whose *rates* live in boxes, certifying separation uniformly over the box. One new fixture, no new rules.

## 19.8 Anchor at the Known Point

**The move.** When you must certify something about an object you cannot compute — a fixed point, a limit, an optimum — do not analyse the iteration that approaches it. **Invert the anchoring: state every hypothesis at the concrete artefact you hold** (the snapshot, the candidate, the last iterate), and let one contraction-style row transport the conclusion to the unknown object. Concretely, for a fixed point  $\mu_*$  of an operator  $T$  and a snapshot  $\hat{\mu}$ :

1. certify a **two-point contraction** on a ball around  $\hat{\mu}$ :  $d(Tx, Ty) \leq \rho d(x, y)$  with  $\rho < 1$ , as checkable rows;
2. certify the **one-step residual** at the snapshot:  $d(T\hat{\mu}, \hat{\mu}) \leq \delta$  — one application of  $T$  to a concrete object, always computable;
3. conclude  $d(\hat{\mu}, \mu_*) \leq \delta/(1 - \rho)$ , with existence *and* uniqueness of  $\mu_*$  in the ball manufactured by the contraction itself (Banach) — no convergence analysis, no iteration count, no history of how  $\hat{\mu}$  was produced.

The inversion matters because the literature’s theorems are usually anchored at the unknown point (“the iteration contracts *toward*  $\mu_*$ ” — a one-point statement at a place you cannot evaluate anything), which is useless as a certificate hypothesis. A certificate’s hypotheses must be checkable, and only the known point supports checking. The two-point form costs more analysis once, in the untrusted lane; every certificate after that is arithmetic at  $\hat{\mu}$ . This section is the producer half of a seam: the checker half is the catalogue’s QFIXBALL rule (chapter 15), whose hypotheses are anchored at the known snapshot by construction and whose refusals include  $\rho \geq 1$ .

The producer-side companions, from the same worked example:

- **Reduce before you certify.** If the operator provably maps everything into a small family (a pinning lemma: any output of  $T$  is Gaussian with known precision, whatever the input), the measure-space problem collapses to a finite-dimensional one — and the reduction is *forced*, not assumed, so the certificate still speaks about the full space.

- **Guess-and-check the spectral row.** The contraction factor  $\rho$  needs a norm bound on a nonnegative matrix; propose a Perron row vector with floats, snap to rationals, and let the checker verify the row inequality. When bare power iteration oscillates (period-2 on a two-block system), iterate  $(R + I)/2$  instead — same fixed vector, damped rotation. Both proposals are sound to check; the fix buys *sharpness*, not soundness — the checker is indifferent, and that indifference is the seam working.

#### When it applies.

- the claim is “the true object is within  $\varepsilon$  of *this*” — distance-to-fixpoint, distance-to-optimum, a posteriori error bounds — rather than “the algorithm converges”;
- every hypothesis you have tried to state mentions the unknown object’s location (a Lipschitz constant “near  $\mu_*$ ,” a curvature “at the optimum”) — the tell that the literature’s anchoring is backwards for your purpose;
- one application of the operator to a concrete object is cheap, even though finding its fixed point is not (one coordinate-ascent sweep versus the converged posterior; one Newton step versus the root; one Bellman backup versus the value function);
- a self-mapped ball is available: contraction plus residual imply  $T(\overline{B}(\hat{\mu}, r)) \subseteq \overline{B}(\hat{\mu}, r)$  for  $r \geq \delta/(1 - \rho)$ , so the hypotheses only need to hold on a set you can name in advance.

Interval-Newton and Krawczyk verification are this move’s classical ancestors in  $\mathbb{R}^n$ ; the move generalizes them to any complete metric space a reduction can reach.

**Worked example from the record.** Certified Wasserstein balls for variational inference. The task: certify that a CAVI (coordinate-ascent variational inference) snapshot is within  $\mathbb{W}_2$ -distance  $r$  of the true self-consistent fixed point.

- The literature’s theorems (contraction of the CAVI iteration [36]) are one-point statements at the unknown  $\mu_*$ . The certificate inverts: all hypotheses at the snapshot  $\hat{\mu}$ .
- The pinning reduction: every CAVI output is exactly Gaussian with precision  $Q_{ii}$  regardless of input, so the fixed-point problem in measure space collapses to an affine map on means — and the certificate quantifies over *all* product measures in  $\mathcal{P}_2$ , not just Gaussian candidates.
- Receipts: ACCEPT with certified  $\rho = 96/181$  against true contraction factor  $3/(4\sqrt{2}) \approx 0.53033$ ; ball radius  $3.6 \times 10^{-7}$ ; ground truth (computed independently, never consumed by the certifier) inside every ball with slack  $\times 1.9$ ; 11/11 mutants refused at named obligations.
- The period-2 Perron oscillation appeared live: the first run’s bare power iteration proposed a loose  $\rho = 3/4$ ; the  $(R+I)/2$  fix recovered sharpness. Both fixture generations were accepted by the checker — a live specimen of the proposer being fallible and the trust boundary not caring (section 19.1, observed end to end).

**The failure mode it prevents.** Without the inversion, the certificate route dead-ends in one of two ways. Either the producer imports the literature theorem as-is and the certificate’s hypotheses quantify over a neighbourhood of a point nobody can locate — unfalsifiable rows, which a checker must either trust (trust-surface creep) or refuse (no certificate at all). Or the producer certifies the *iteration history* (“ $n$  steps, each contracting”) — which couples the certificate to the trajectory that produced the snapshot, breaks on restarts and warm starts, and still needs the contraction constant somewhere. The anchored form is history-free: any snapshot from any source, certified on its own merits — a corrupted snapshot simply fails the residual row (refusal, not a lie).

#### Exercises.

1. **Block-Gaussian instance** — the worked example’s blocks were scalars; run the same pattern with matrix blocks, exercising operator-norm rows proper. Everything is staged; only the fixture generator changes.

2. **Discrete instance (2-spin Ising)** — the total-variation contraction is free at bounded couplings; this produces the first *discrete* Wasserstein-ball fixture and tests whether the move survives leaving the Gaussian reduction.
3. **The covariance fold-in** — fold covariance error into the ball (dropping the variance-exactness refusal); the disanalogy to price is that the mean-map affinity no longer collapses the whole problem.
4. **The transfer question**, worth a page before any build: which of your own stack’s implicit objects (stationary laws of samplers, Bellman fixed points in value-iteration producers) already have a cheap one-step residual and are one two-point contraction row away from an anchored ball?

## 19.9 Safety Walls and Liveness Tilts

**The move.** A specification that asks a system to be *robustly safe while optimistically achieving a goal* has two halves of opposite character, and most threshold-reading errors in probabilistic specification come from applying one half’s natural reading to the other. The move is to give the two halves opposite **polarities**, explicitly:

1. **Safety is a probability claim, read violation-form: a wall.** Budget the mass on the bad event —  $P(\text{bad}) \leq \beta$  — and hold violation infinitely inconsistent: the belief (the level-of-inconsistency functional of chapter 9) is 0 on the half-space where the budget holds and  $\infty$  where mass on the bad event exceeds it, with nothing in between. In particular, the run that halts, idles, or leaks mass incurs no inconsistency — *a system that stops has not hit the wall*. This is not leniency but correctness: safety is closure-invariant — adding stopping behaviours to a safe system cannot make it unsafe, and leaked mass can only lower the probability of reaching the bad event (chapter 9 carries this asymmetry as a theorem of the partial-model semantics).
2. **Liveness is an expectation claim, read as a tilt: a hinge.** Price the shortfall of the good event’s mass below its target  $\tau$  at a finite rate —  $\lambda \cdot (\tau - \mu(\text{goal}))_+$  — and charge nothing at or above the target. Beliefs take values in  $[0, \infty]$  (the Lawvere quantale: there are no negative levels of inconsistency), so the shortfall is a saturated difference, written  $(\cdot)_+$ , never a signed one. The hinge’s two sides carry the reading: the flat side means overachievement is free and buys nothing — in particular it cannot be traded against the wall — and the sloped side means a near-miss is *priced*, not merely refused, which is what “optimistically” means as mathematics.

The two readings are one family, not two species: as  $\lambda \rightarrow \infty$  the hinge steepens around its kink at  $\mu(\text{goal}) = \tau$  and converges — in the epigraph sense, the right sense for beliefs — to the hard threshold: 0 at or above the target,  $\infty$  below. A *hard* liveness threshold is therefore the  $\lambda = \infty$  endpoint of the tilt, satisfaction-form as it must be: the run that does nothing fails it, and should — that is what a hard liveness threshold *means*. Choosing  $\lambda$  is choosing where on the family the claim lives; the trap (below) is only ever reading a threshold at the wrong polarity, never choosing a finite  $\lambda$  on purpose.

Compose by maximum:  $\max(\text{wall}, \text{hinge})$  is the conjunction of beliefs, and it is **convex** — the wall is the  $\{0, \infty\}$ -indicator of a half-space, the hinge is a maximum of an affine function with zero, and a pointwise maximum of convex beliefs is convex. Certification inherits the cheapness: half-space walls, FARKAS combination, and the ReLU row family (ReLU-Pos, ReLU-Above and kin, chapter 15) — whose native object is exactly  $\max(\text{affine}, 0)$  — already span the composite. The payoff sentence: the standard reach-avoid specification, in its robustly-safe-while-optimistically-live form, costs nothing the toolkit does not already ship.

### When it applies.

- Any specification with a “never / at most” half and an “eventually / at least” half: reach-avoid, stabilize within bounds, achieve a return under a resource budget. The two halves are both thresholds, and they need opposite readings.
- Whenever the modelled system can halt, diverge, exit scope, or otherwise leak mass — partiality — so that the two readings of a threshold genuinely differ. The recognition question is: “what does this specification say about the run that does *nothing*?” If safety and liveness give the same answer, a polarity has been misassigned.

- Whenever you meet a bare threshold — yours or someone else’s — that does not carry its reading. The natural default flips sign between the two halves, so “which polarity did the author mean?” is a question to settle before consuming the row, not after.
- When composition or certification cost binds: the wall-plus-tilt composite stays convex, so the polarity discipline is also what keeps the composed specification in the cheap, Farkas-certifiable class.

**Worked example.** Three outcomes suffice: REACH (the goal), AVOID (the bad set), INERTIA (the run that never commits — halts, idles, diverges). A distribution  $\mu = (\mu_R, \mu_A, \mu_I)$  over the three is a point of the probability 2-simplex, and the specification reads: *reach with probability at least  $\frac{3}{4}$ , never more than  $\frac{1}{4}$  on the bad set*. The safety wall is the violation half-space  $\mu_A > \frac{1}{4}$  penalized at  $\infty$ ; the liveness tilt is the hinge  $\lambda \cdot (\frac{3}{4} - \mu_R)_+$ . Four distributions — the three vertices and one genuine mixture — against the wall, the hinge at two rates, and the hinge’s hard limit:

|                        | $(\mu_R, \mu_A, \mu_I)$                     | wall     | $\lambda = 4$ | $\lambda = 40$ | $\lambda = \infty$ |
|------------------------|---------------------------------------------|----------|---------------|----------------|--------------------|
| commits to the goal    | (1, 0, 0)                                   | 0        | 0             | 0              | 0                  |
| commits to the bad set | (0, 1, 0)                                   | $\infty$ | 3             | 30             | $\infty$           |
| never commits          | (0, 0, 1)                                   | 0        | 3             | 30             | $\infty$           |
| the mixed run          | $(\frac{7}{10}, \frac{1}{20}, \frac{1}{4})$ | 0        | $\frac{1}{5}$ | 2              | $\infty$           |

Read the columns against the doctrine. The **wall** distinguishes the two failures the hinge cannot: committing to the bad set hits it, never committing does not — failing dangerously and failing idly are different verdicts, and only the violation-form reading can tell them apart. The **hinge** carries the orthogonal information: the mixed run, with  $\mu_R = \frac{7}{10}$  against the target  $\frac{3}{4}$ , certifies at *every* finite  $\lambda$ , paying the priced shortfall  $\lambda \cdot \frac{1}{20}$  — the optimistic reading, a near-miss ranked rather than refused — while any distribution at or above the target pays exactly 0 on the flat side. And the  $\lambda = \infty$  **column** is the hinge steepened into the step: the mixed run and INERTIA now both fail, which is correct precisely when the claim intended is the hard one. The composite  $\max(\text{wall}, \text{hinge})$  needs both columns’ information: drop the wall and dangerous failure is merely priced (a large enough achievement elsewhere could dominate it); drop the hinge and every near-miss collapses into undifferentiated refusal.

Where this stands in the toolkit at this preview. The probability-threshold former SPROBGE (chapter 14) is a mass floor — lower probability at least  $p$  — i.e. the  $\lambda = \infty$  liveness endpoint, and the credal semantics makes it feel every lost unit of mass, exactly as a hard liveness claim should (chapter 9: a liveness claim cannot be laundered through a model that is allowed to quietly stop). Safety already runs at the other polarity internally: the safety batteries’ certified object is an upper bound on the violation mass ( $\overline{P}(\text{bad}) \leq V(x_0)$ , the threshold row of QSafetyBATTERY and kin), which is why those certificates remain sound under leak — the wall reading is already how the machinery works. The expectation formers (SRETURNGE/SRETURNLE, chapter 14) are the shipped expectation-claim species that carry the tilt: a hinge belief over an indicator channel is an expected-shortfall bound. And the polarity itself is declared in the grammar — as a sort, which is stronger than a field: the specification cap (chapter 14) types every threshold component by its face, so a mis-faced premise is a formation error, refused before any semantics runs, and each former’s reading is definitional in the certificate theory rather than a habit of its author. One disambiguation earns its keep here, because that chapter also says “safety face” and means a different axis by it. The cap’s polarity answers *who quantifies over the admitted laws*: a ForallSpec component binds every law, an ExistsSpec component asserts some law attains. This section’s polarity answers *which way a single threshold faces*: wall on the violation mass, floor on the goal mass. The two axes are independent, and one specimen shows how far apart they sit: SPROBGE — this section’s hard *liveness* endpoint — concludes ForallSpec, the credal *safety* face, because demanding the goal’s mass from every admitted law is a guarantee about a floor. What remains the author’s is this section’s own discipline: the grammar refuses a mis-faced component, and no grammar can refuse a wall aimed at the wrong event.

**The failure mode it prevents.** One trap, two signs, plus the composite’s own failure:

- **Liveness read violation-form forgives doing nothing.** Two outcomes; a system that succeeds with probability  $\frac{2}{5}$  and otherwise halts; the claim “reach success with probability at least  $\frac{1}{2}$ .” The violation-form misreading — refuse only if mass on the *failure* event exceeds  $\frac{1}{2}$  — sees zero mass

on failure and passes, but  $\mu(\text{success}) = \frac{2}{5} < \frac{1}{2}$ : the mass floor fails, and the correct verdict is refusal. Liveness laundered through leak — the quietly-stopping system certified for a goal it does not deliver.

- **Safety read satisfaction-form punishes halting as if it were violation.** Spell “avoid the bad set” as a floor on the safe-completion event and the safely-idling system fails, though it never approaches the bad set. The downstream rot is worse than the false refusal: an author who knows the system may stop weakens the floor to tolerate it, and the weakened floor now also tolerates genuine violation mass. The repair was never a looser constant; it was the other polarity.
- **The negotiable wall.** Price safety at a finite rate — treat it as one more tilt — and conjunction-by-maximum degrades into trade: enough achievement elsewhere dominates a bounded safety belief, and the optimizer will find that trade. “Robustly” means the wall is not for sale at any exchange rate, and only the violation form at infinite inconsistency says so.

Two polarities, no trap: liveness formers are satisfaction-form by definition, hard at  $\lambda = \infty$  and tilted at finite  $\lambda$ ; the safety machinery is violation-form by construction; and the reading travels with the claim as data instead of living in the reader’s habits.

### Exercises.

1. **The face mutants, now that the sort has shipped.** The cap’s polarity discipline — a mis-faced premise is a formation error — is a refusal, and this chapter’s own doctrine applies to it (section 19.3): a refusal without a firing witness is indistinguishable from dead code. Build the formation battery, each mis-faced construction fed to the grammar with its refusal location asserted — and include the one cell no formation check can own: the laundering-through-leak specimen above, a floor swapped for a wall on the complementary event, which is well-formed at both faces and wrong only about what the author meant. That last mutant’s home is the semantic tier (the flipped reading asserted against the partial-model semantics and refused there), and placing it correctly is part of the exercise.
2. **The epi-limit, certified.** The one-family claim — the hinge at rate  $\lambda$  converges in the epigraph sense to the hard threshold as  $\lambda \rightarrow \infty$  — is stated here as belief mathematics. Formalize it against the belief semantics, so that a hard liveness former and the  $\lambda = \infty$  tilt are interchangeable obligations in one worked certificate rather than two spellings the reader must trust to agree.
3. **The composite on a shipped witness.** The spec catalogue’s hitting-shape witness (goal reached by deadline with probability at least  $\frac{3}{4}$ ) is a hard liveness claim beside a safety wall. Restate it composite-form — wall on the bad set, hinge on the goal mass at two finite rates — and produce the certificate with half-space walls, FARKAS, and ReLU rows only; then check that the  $\lambda = \infty$  run of the same pipeline recovers the original hard claim. Success condition: the composite certifies with no row species beyond the shipped roster, and the two finite- $\lambda$  certificates price the same shortfall the table above prices.

## PART IV

# Appendices

---

# The Lean Cone

---

Throughout this book, claims that lean on a mechanized result cite the result by its Lean name, set in typewriter face. This appendix collects those citations into one place: for every cited declaration, it reproduces the declaration’s statement from the `lean/` trees of `maitria-coalition/qtsl`, with its file and line. We call this set the *Lean cone* of the book: the set of mechanized results the book’s prose binds to, closed under nothing — what you see is what the text actually cites, re-derived from the sources on every build, so the listing cannot drift from the tree it describes.

A word on how to read the entries. Statements are reproduced at signature level: a theorem up to its proof, a definition up to its body, a structure up to its fields (an ellipsis marks the elision), and long source lines re-wrapped to the measure of the page. Each entry is shown in the namespace where it lives, and surrounding context (open and variable declarations, notation) lives in the cited file, so an entry here reads as a faithful excerpt rather than a self-contained module. To verify an entry, clone the repository and run `lake build` inside the relevant Lake package under `lean/` (for example `lean/qtsl` or `lean/su-functor`); the toolchain is pinned by each package’s `lean-toolchain` file, and a build that succeeds has kernel-checked every statement listed here, since none of the trees admits sorry.

Two boundaries of the cone, so that its edges are as legible as its contents. First, the Rule Catalogue displays a Lean or HOL4 statement beside each rule already, extracted from the mechanized rule sources and hash-bound at emission; this appendix lists the catalogue’s citations that resolve into the `lean/` trees of this repository and defers to the catalogue’s own apparatus for its rule-source and HOL4 layers. Second, module citations (a dotted name denoting a whole file or directory of results) are listed per chapter without statements; the module’s file is the reference.

The listing follows the book’s chapter order, and each declaration appears once, under the first chapter that cites it; later chapters that cite the same result say so in a closing line rather than repeating the statement.

## A.1 The Semantic Universe
